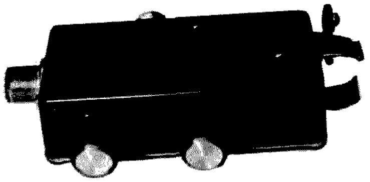
R-X Noise Bridge



- **Learn the truth about your antenna.**
- **Find its resonant fequency.**
- **Adjust it to your operating frequency quickly and easily.**

If there is one place in your station where you cannot risk uncertain results it is in your antenna.

The Patomar Engineers R-X Noise Bridge tells you if your antenna is resonant or not and, if it is not, whether it is too long or too short. All this in one measurement reading. And it works just as well with ham-band-only receivers as with general coverage equipment because it gives perfect null readings even when the antenna is not resonant. It gives resistance and reactance readings on dipoles, inverted Vees, quads, beams, multiband trap dipoles and verticals. No station is complete without this up-to-date instrument.

Why work in the dark? Your SWR meter or your resistance noise bridge tells only half the story. Get the instrument that really works, the Palomar Engineers R-X Noise Bridge. Use it to check your antennas from 1 to 100 MHz. And use it in your shack to adjust resonant frequencies of both series and parallel tuned circuits. Works better than a dip meter and costs a lot less.

The price is $59.95 in the U.S. and Canada. Add $3.00 shipping/handling. California residents add sales tax.

Send for FREE catalog describing the R-X Noise Bridge and our complete line of SWR Meters, Preamplifiers, Toroids, Baluns, Tuners, VLF Converters, Loop Antennas and Keyers.

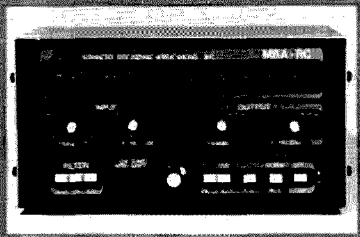
FLEXIBILITY



AEA once again breaks new ground in the code communications field with the new model MBA-RO reader/code converter. The MBA-RO decodes Morse, Baudot or ASCII signals off the air and displays them on a large 32 character alphanumeric vacuum fluorescent display. In addition, it will output Morse code for keying your transmitter. It will also generate RTTY (Baudot or ASCII AFSK two tone output. (170 or 850 Hz shifts.) Any of the acceptable input codes can be converted to any of the specified output codes (any speed to any speed). If you have any of the common Baudot RTTY terminals as an example, you can now send and receive Morse and ASCII with your keyboard and printer. You can even generate ASCII or BAUDOT RTTY using your Morse hand key or memory keyer.

Get the details. Write for our free product catalogue or better yet, see your favorite dealer.

Prices and Specifications subject to change without notice or obligation.

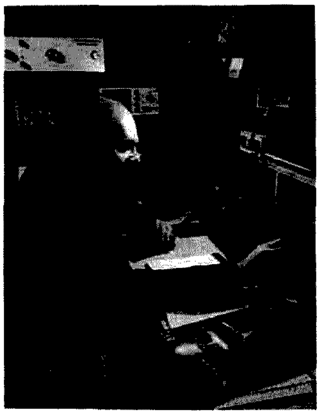
W2NSD/1
NEVER SAY DIE
editorial by Wayne Green



IT'S SNOW FUN

Are you going to be wasting your time the second week of January chasing some fool DXpedition around twenty meters or are you going to be out with a bunch of us on the slopes of Aspen, HTing it and having a ball? That's the low season in Aspen, so the prices are still a bargain. . . and it's right after the Winter Consumer Electronics Show in Las Vegas, if you're in the electronics industry.

During the day, Chuck Martin WA1KPS (Tufts Electronics) will be leading the kamikaze group down the expert slopes, while I'll be struggling to keep up with the geriatric crowd and their walkers on the gentler slopes. It is a lot of fun to ski with fellow hams. . . keeping in touch with HTs. And it's even more fun to get together for dinner at some of the famous Aspen restaurants and talk over the ham industry, DXing, and so on.

If you can get away January 8-12, we'll be skiing out of The Limelight Hotel (again), so don't miss the Eighth Ham Industry Winter Symposium. . . obviously an historic event. We're expecting ham manufacturers there as well as dealers, so there should be some brisk discussions on discounts, service support, needed new products, technical advances, and so on.

THE VIEW FROM OVERSEAS

With such a heavy percentage of our DX contacts going not much further than an exchange of names, locations, and, possibly, in some rare cases, a recitation of the equipment being used, not only are we failing most of the time to live up to one of the fundamental rationales for amateur radio—the development of international friendship—but also we are wasting an impressive technology. When is the last time you got on the air and had a half-hour contact with someone in a relatively rare DX country?

Rather than lecture you and try to make you feel guilty for maintaining the most eternal tradition of amateur radio, meaningless contacts, I'd rather go about this in a positive fashion. I recognize that one of the problems when you meet someone new is to find a field of mutual interest about which to talk. Most of us are so used to our own areas that we tend to forget that though they are pedestrian to us, they might be of considerable interest to someone overseas.

Sure, the chap in a small town in Germany will go to a fair in his area just as you may in yours. But there the similarity ends. While the fair I go to may offer Italian hot-sausage sandwiches with fried onions and green peppers, fruit salad, green salad in a pita-bread pouch, fried dough, french-fried onion rings, french fries, do-it-yourself ice cream sundaes, and corn on the cob, my friend in Germany will be eating a wide variety of sausages, hot potato salad, grilled fish, pigs' knuckles, shashliks, and drinking new wine or a special seasonally-produced type of beer. At French fairs, the fare is again different, but no less delicious.

In order to work toward bringing amateurs together on a worldwide basis, I'd like to solicit regular reports on hamming overseas via a group of correspondents. If you are living in some area of the world which should be reported on in *73*. . . or if you know someone who might be interested in such, I'd like to hear from you.

What I have in mind is a regular. . . perhaps monthly for many areas. . . report on any news of interest to hams around the world. I think many of us would like to know about contests which are coming up which are organized in your area. We'd like to know about new certificates. We'd like to know about any outstanding ham conventions. We'd like to know about ham products which are made in your area. We'd like to know more about the growth of hamming, any special developments, important rule changes, how to get a visitor's license, and so on.

What areas? I'm open to suggestions. Perhaps we'd like to hear from the U.K., Germany, France, Benelux, Scandinavia, Southern Europe, the Mediterranean area, the Mideast, India, Japan, Southeast Asia, Australia-New Zealand, Oceania, South America, the Caribbean. . . and so on?

Regular correspondents will not only be paid for the reporting work, but also will get special press passes from the magazine, special QSL cards, business cards, and other such documents to help them with their reporting contacts.

This would be a good medium for bringing up area problems for world discussion. It would help us know more about coming and past DXpeditions. We might be able, with such a widespread correspondent system, to develop some sort of network of ham help to meet traveling hams and make them welcome. We would be better able to keep things like local net frequencies known, repeater channels publicized, and so forth.

I would love to have some correspondents from Iron Curtain countries, recognizing that they might prefer to be paid in magazine subscriptions and books rather than American cash, which can be a problem.

If you have any good friends in spots around the world who you think might be able to provide a continuing series of interesting reports, you might drop them a line with a copy of this editorial and suggest the idea. Or you could bring it up on the air. . . give you something of interest to talk to them about. The prestige of being published in an international magazine can help a person substantially, sometimes. I remember when I first ran into that. It was in 1956 and I was visiting St. Thomas and Dick Spenceley KV4AA. I was the editor of *CQ* at the time, which I didn't think of as being of much importance. Well, I stopped by a store downtown, happened to mention Dick, and was told how important he was, doing a DX column for an international magazine! Hmmm. It

NEW BAND APPROVED

The FCC has approved use of the 10-MHz band, but amateur operation is limited and the Commission did not release the new rule without a cautionary note.

According to the rule, most of the frequencies from 10.1 to 10.15 MHz are available to hams, except for a slice from 10.109 to 10.115 MHz. That section is still reserved for government use.

General-, Advanced-, and Extra-class licensees are allowed to transmit CW and RTTY (FSK and AFSK) with a final input power of up to 250 W. In its decision, the Commission cited the "limited size" of the band and the "temporary nature" of the ruling.

The FCC's action is valid until the Senate takes action on the WARC treaty, leaving present limitations open for change. Although 30 meters has been a possibility since the 1979 WARC convention, approval of the treaty was delayed.

Though the FCC previously denied an ARRL petition requesting use of the band, the amendment did not directly address the Commission's change of mind.

"Strong interest" in the amateur community was cited as a reason for the decision, but the Commission warned that since its action is subject to future Senate decisions about the treaty, the amendment "may be effective for only a brief period."

The FCC added that hams would be "ill-advised to invest heavily in equipment which can only be used in this band."—WB8JLG.

sure cut a lot of ice in St. Thomas. I was sorry to hear that Dick passed away recently... we'll all miss that incredible fist of his. Any serious CW operator could tell Dick instantly by the perfection of his fist.

Please give me a hand with this so that we can bring amateurs worldwide together a bit. The end result will be a lot more interesting things for us to talk about... perhaps bringing more DX operators onto our bands. Ops in rare countries sure get sick of endless demands for instant contacts and QSL cards. I get ham magazines from the U.K., South Africa, Malaysia, Australia, and so on, so I have a fair idea of what is going on... but 99.99% of you don't have that sort of input or the resources to pay for such a wide variety of magazines. Columns devoted to

QSL OF THE MONTH

This month's winning QSL comes from a Baptist mission in Kenya, the home of Milton (5Z4CL) and Charlotte (5Z4CM) Ertelt. The design is simple and informative, using only two colors to achieve a striking contrast.

Few cards are as succinct as this one, telling the reader at a glance where in the world the station is located. And from a distance, Charlotte and Milton's calls stand out clearly, leaving no doubt that this QSL is probably the pride of many a DXer's shack.

Entering *73*'s QSL contest is easy—send your QSL, in an envelope, to: Editorial Offices, *73*, Peterborough NH 03458. Specify a book from *73*'s Radio Bookshop; if your card is chosen, we'll be happy to send the book along to you. Entries which are not in an envelope or do not specify a book will not be considered.

Well... I Can Dream, Can't I? by Bandel Linn K4PP

Action Machine for 20

Are home-brew rigs a lost art? Not yet! Here's an SSB transceiver you can build.

I designed and built mini'ceiver 20 to learn something about SSB transceiver design. Several times in the course of the project I became convinced that I was learning more about SSB transceiver design than I ever wanted to know! Anyway, mini'ceiver has worked out and it's quite a conversation piece on the air. You can run mini'ceiver from a lantern battery, which opens up a number of possibilities. I have made an effort to use readily-available parts and easy-to-tune circuits in mini'ceiver, so I feel you will have a good shot at making it work if you want to give it a try.

This article covers mini'ceiver's circuit operation once over lightly and then, in some detail, the circuit schematics. No math or theory here, just a shirt-sleeve discussion of the circuitry and how well it seems to work. If you are game at this point, I'll then give you some hints on how to build and tune up mini'ceiver, and I'll wind up with some ideas on accessories, possible design alternatives, and operation. If you've always wanted to build a good size project from scratch but never quite got around to it, this article is written for you. I'll try to give you an idea of what you've been missing.

Photo A. Mini'ceiver 20 is an SSB transceiver boiled down to the basics.

Mini'ceiver Circuit Operation

Let's first look at Fig. 1, mini'ceiver's block diagram. Mini'ceiver is a 20-meter single-conversion superheterodyne transceiver boiled down to the basics. A conventional 9-MHz i-f frequency is used.

In the receive mode, an incoming signal in the 14.25-14.30-MHz range is routed through the receiver antenna switch to a dual-gate MOSFET mixer where it is mixed with the vfo signal (vfo range is 5.250-5.300 MHz). The mixer's difference output, at 9 MHz, is routed through the receiver side of the T/R filter switch to the four-pole crystal filter, which provides the receiver's selectivity. The i-f output from the crystal filter is amplified by a single-stage IC amplifier which can provide a voltage gain of up to about 1000. The output from the i-f amplifier is mixed with the 8.9985-MHz bfo in the MOSFET product detector, recovering, typically, 5 mV of audio.

The audio output from the product detector is amplified by the low-level audio amplifier and then routed to the agc amplifier and the volume control. The agc amplifier further amplifies the audio to around five volts peak-to-peak and then detects this signal to develop the agc control voltage. Meanwhile, audio from the volume control is routed to the audio power amplifier and on to the speaker jack. While in the receive mode, the transmit circuitry is disabled by switching off the +T supply voltage.

In the transmit mode, the +T voltage is switched on as the +R voltage is switched off, enabling the transmitter circuitry as the receiver circuitry drops out. Low-level speech signals from the microphone are amplified to about 1.5 volts peak-to-peak by the speech amplifier and applied to the balanced-modulator audio input. Here the audio is mixed with the bfo signal in an IC double-balanced mod-

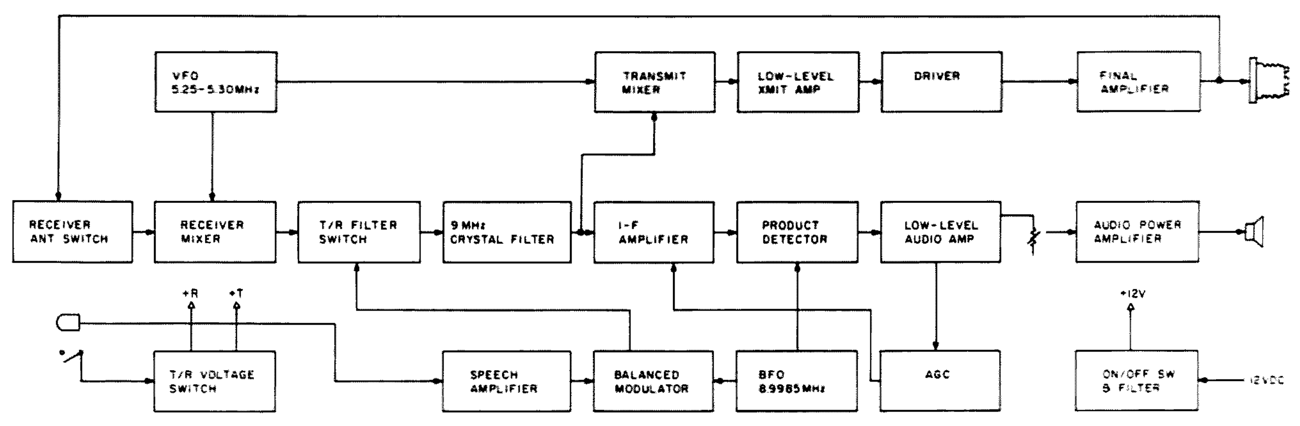

Fig. 1. Mini'ceiver 20 block diagram.

ulator. The double-sideband output from the modulator is routed through the transmit side or the T/R filter switch to the crystal filter. The crystal filter strips off the unwanted lower sideband and routes the 9-MHz SSB signal to the transmit mixer. At the transmit mixer, the 9-MHz SSB signal is mixed with the vfo signal and the sum output at 14 MHz is developed in the transmit mixer's tuned output circuit.

The 14-MHz SSB signal next is amplified by two MOSFET low-level transmit amplifiers to about 600 mV peak-to-peak. The driver stage boosts this signal to about 200 mW and the final amplifier to about 1.5 W. The output from the final is sent to the antenna. Since the receiver antenna switch is open in the transmit mode, the receiver mixer is protected from overload.

The +R and +T power-supply voltages are alternately switched on under the control of the microphone PTT switch. All in all, mini'ceiver is a simple and straightforward design.

T/R Voltage Switch

Almost every modern SSB transceiver design incorporates digital logic, and mini'ceiver is no exception. Refer to Fig. 2, the T/R voltage switch schematic. A 4093BE CMOS quad Schmitt NAND gate is the heart of this circuit. When the PTT switch is open, +12 V dc is applied to R1 and on through the gate interconnections to pull R3 low at pin 10. This turns on Q1 and supplies +R to most of the receiver circuitry. +R also turns on Q4, which helps pull down the +T voltage on a transmit-to-receive transition. Meanwhile, pin 11 is at +12 V dc and Q2, +T, and Q3 are off.

When the PTT switch is closed, the input side of R1 is grounded, which first allows pin 10 to go to 12 V dc, shutting off Q1 and Q4. About 30 milliseconds later pin 11 will go low, turning on Q2 and Q3, supplying +T to the transmit circuitry and clamping +R to ground. R2 and C3 account for the time that both +R and +T are off during a receive-to-transmit or transmit-to-receive transition. R1 and C2 simply form a glitch filter. Schmitt inputs were chosen for reliable logic switching with the slow rise times provided by R1-C2 and R2-C3.

The vfo, bfo, audio power amplifier, and the collectors of the transmitter driver and final amplifier are continuously supplied with +12 V dc from the input power jack. C1 provides dynamic filtering for operating from dry cell batteries, etc.

Vfo and Bfo

Fig. 3 provides the vfo and bfo schematics. We'll start with the latter. The bfo is a grounded-base crystal oscillator designed to work with a series-resonant 8.998500-MHz crystal. It is easily tuned ± 300 Hz, which allows you to tailor the "sound" of the rig somewhat. It will provide a 5-V peak-to-peak output when loaded by the product detector and balanced modulator. Note that it is enclosed in a minibox. This is a must. I first had the bfo circuit on the receiver main board. I also had about two volts of bfo in the i-f amplifier output, plus all the local AM radio stations, etc! Keep the bfo shielded from the i-f amplifier; that is sage advice.

The vfo consists of a buffered Hartley oscillator designed along recently-published guidelines.[1] I found the vfo to be quite stable. Tuning is very fast; you may want to use a reduction drive if you don't have a steady hand. R18 allows the vfo output to be adjusted to 5 V peak-to-peak. The vfo also is built in a minibox, primarily for its own protection. The box helps stabilize temperature and shield the vfo from other rf signals.

Receiver Rf Section

CR3, CR4, R24, R25, R26, C28, and C29 form the receiver antenna switch. In the

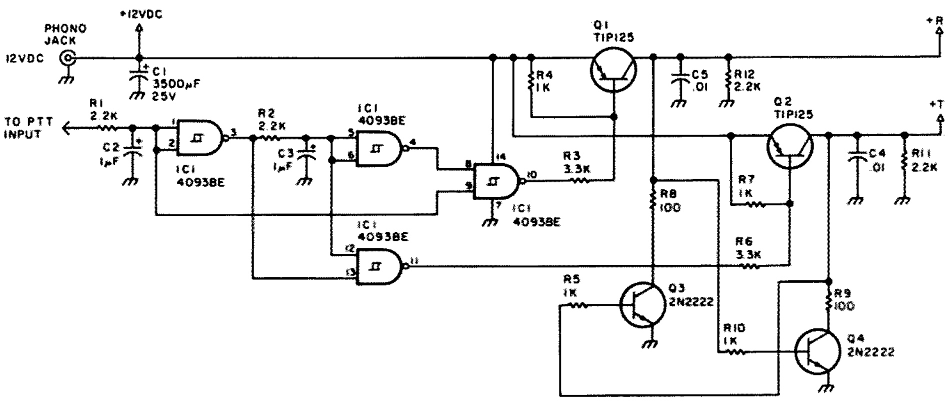

Fig. 2. T/R voltage switch.

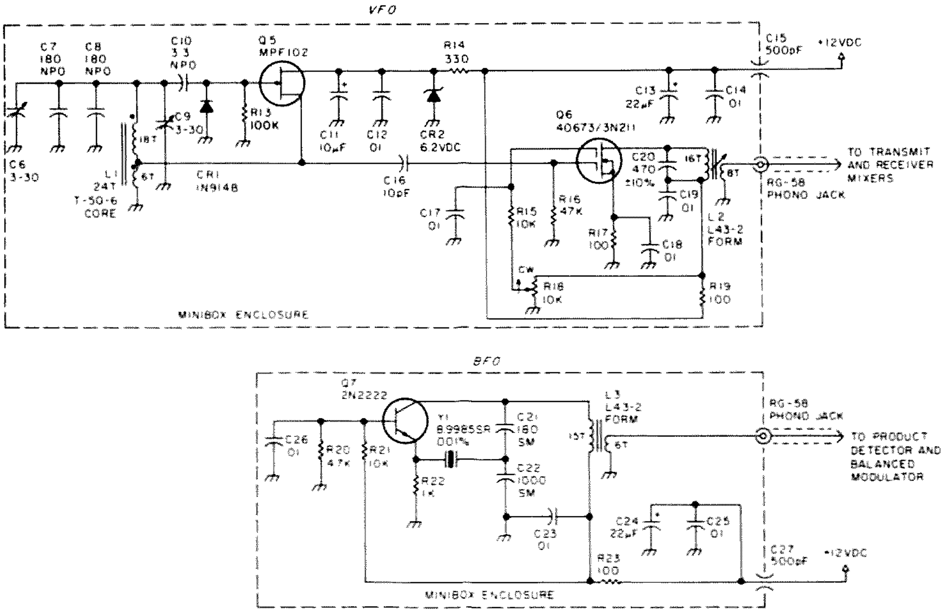

Fig. 3. Vfo and bfo schematics.

receive mode, R25 supplies current to CR3-R24 and CR4-R26 from +R. CR3 and CR4 are forward-biased with about 5 mA dc and appear to small rf signals from the antenna as 25-Ohm resistors. Receiver signals thus easily can pass through C28 and C29, which are dc blocking capacitors, and the two forward-biased diodes to the input transformer of the mixer.

When the bias to the diodes is removed in the transmit mode, the diode switch opens. Notice that when the rf output from the final amplifier is positive, CR3 is reverse-biased so little signal makes it to the mixer input transformer. When the rf output from the final is negative-going, CR3 is forward-biased so the rf signal appears at R25. However, CR4 is now reverse-biased, blocking the rf output from reaching the mixer input.

The use of this type of diode switch eliminates the need for a mechanical relay. Purists would probably add some rf chokes in series with the biasing resistors and might use PIN diodes; however, I'm not a purist —just cheap.

The receiver mixer employs the often-used 40673 (Q8) which is adequate for this application. We now come to the second diode switch in the mini'ceiver, which is used to switch signals to the crystal filter from either the receiver mixer or the double-balanced modulator. CR5 forms half the switch; CR8 (Fig. 6) forms the other half. When +R is on, CR5 is conducting about 6 mA dc, again providing a low-loss path to small rf signals. Meanwhile, CR8 is back-biased, isolating the balanced modulator from the receiver-mixer output and crystal-filter input. R30 is the biasing resistor for CR5. R31 establishes a suitable input impedance for the crystal-lattice filter.

The crystal-lattice filter uses four crystals, two cut for series-resonance 750 Hz below center frequency and two cut for series-resonance 750 Hz above center frequency. The overall 6-dB bandwidth appears to be about 2200 Hz. Unwanted sideband suppression is around 26 dB (5%) at 1000 Hz, which is OK for QRP.

While the filter can be built for under $30, you won't hurt my feelings if you use a commercial filter here. Remember to adjust R31 and R32 to suit the commercial filter's termination impedance if you decide to go this route.

I've always had good luck with the MC1350 i-f amplifier (IC2). It exhibits high but stable gain when properly terminated and smooth forward agc action, assuming you keep the bfo signal out of it. The value of R40 and the turns ratio of L6 were chosen for high stable gain. I

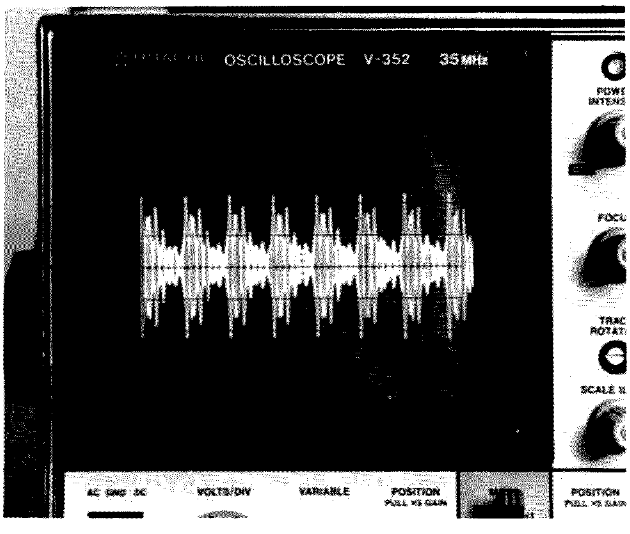

Photo B. Typical mini'ceiver SSB voice waveform. About 1.5-W p-p output.

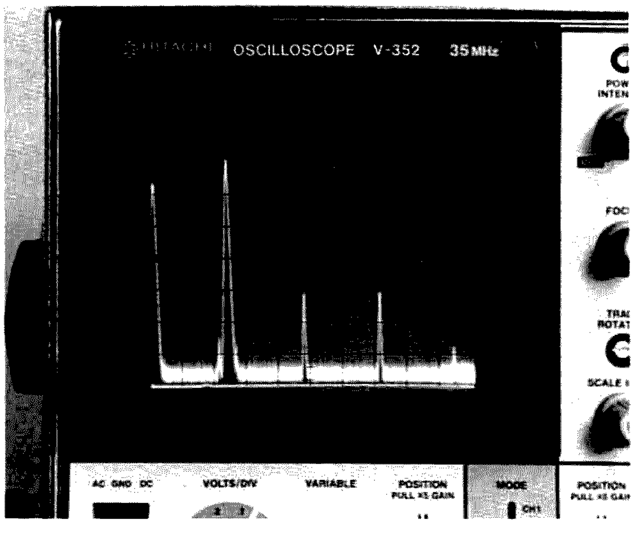

Photo C. Output spectrum consists primarily of the fundamental and harmonics. All spurs are more than 40 dB down.

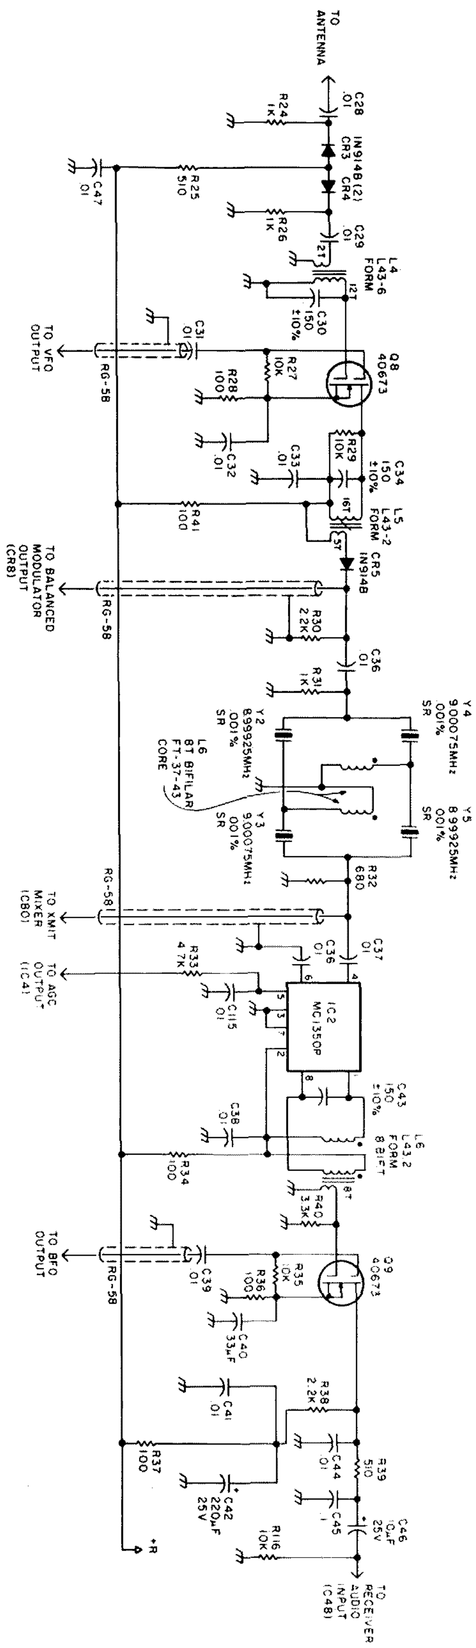

Fig. 4. Receiver rf schematic.

don't suggest pushing the IC harder by raising the value of R40. You don't need the extra gain and accompanying headache.

The faithful 40673 MOSFET is again in service as a product detector at Q9. Notice the heavy audio bypassing and decoupling.

Receiver Af Section

Refer to Fig. 5. An LF353 dual op amp (IC3) is used as the receiver low-level audio amplifier. R47 allows the audio gain to be trimmed out to suit. C50 and C51 help roll off the high-frequency response of the audio section. The LM383 audio power amplifier, IC5, is somewhat of a power overkill, but it provides low-distortion audio at normal listening levels—much better than trying to push an underrated audio section too hard.

IC4 is another LF353, this time used as an agc amplifier and detector. I seem to get the best results with audio-derived agc when the base audio frequencies are rolled off—which explains the small value of C54. R57 controls the agc attack time and R58 controls the release time. Of course, changing C58 messes up both time constants. Agc characteristics are quite subjective, so feel free to experiment here. You might consider agc something of a luxury on a basic transceiver. On 20 meters, I don't.

Speech Amp, Balanced Modulator, and Transmit Mixer

Fig. 6 details the above-mentioned circuitry. Again an LF353 is used as a two-stage audio amplifier (IC6). This time it is rigged to provide a high-impedance input to the microphone. Since high-impedance audio circuits make me nervous, I heavily decoupled the input from rf. A 1496N double-balanced mixer (IC7) is employed as the balanced modulator and works quite well. At least 40 dB of carrier suppression is easily obtained by adjusting R77. Notice the other end of the T/R filter switch (CR8) at the output of the balanced modulator.

After being routed through the crystal filter to do away with the lower sideband, our 9-MHz SSB signal is ready to be translated to 14 MHz. It was at this point that I started learning too much about SSB transceiver design. I won't bore you with all the mixer circuits that didn't work. Let me just say that I have seen just about every picket fence display on my spectrum analyzer that I could imagine (see "Poor Man's Spectrum Analyzer," *73*, August, 1982). The biggest problem was the 3rd harmonic of the vfo at 15 MHz. Now you can supposedly get this out with a carefully designed multipole bandpass filter, but it sort of compromises our simple-to-build theme. Fortunately, there is another way.

First, start with a 1496N double-balanced mixer. Next, don't drive the carrier port (pin 8) with more than 70 mV peak-to-peak of vfo signal. This leaves the mixer pretty much in "linear" operation so that not much 3rd harmonic of the vfo appears in the mixer output. (Refer to the spectrum photo, which tells the story.) Anyway, we now have a clean 14-MHz SSB signal, so on to the transmit amp chain.

Transmit Amplifier Chain

Referring to Fig. 7, we find the transmit amplifier chain uses both tuned and broadband stages. Q11 and Q12 are tuned low-level amplifier stages. There is more potential gain in these stages than needed, so the turns ratio at L9 is not for impedance matching, it's to "throw away" some extra gain without lowering Q. The turns ratio at L10 provides a suitable match between the drain of Q11 and the 30-Ohm or so input im-

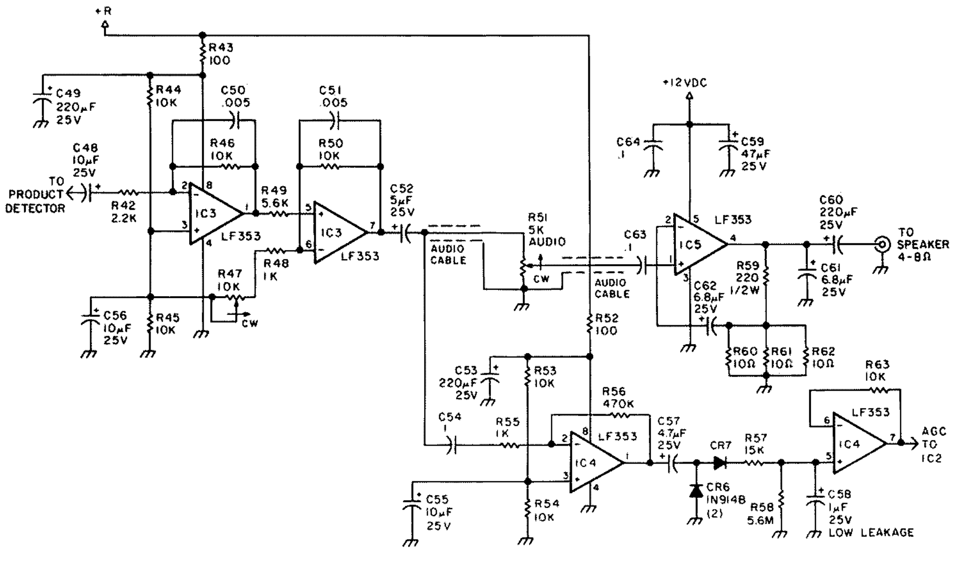

Fig. 5. Receiver af schematic.

pedance of the driver. The driver is the broadband stage. The same feedback that sets the broadbanding on this stage pretty much ensures low-frequency stability, which is what I was after. It seems a little hard to find a suitable driver for HF work, but the 2N3866, which often is used in cable TV systems, is very easy to find. Since it is a VHF transistor, feedback for the sake of stability seems prudent in an HF driver application.

L12 matches the output of the driver to the 5-Ohm or so input impedance of the final amplifier. A single pi network of rather low Q transforms the assumed 50-Ohm antenna impedance to around 35 Ohms, setting up the 1.5-W output with some room to spare. L16 and C108 form a series-resonant trap that takes care of the 2nd harmonic, which is the only offending spur. Notice that the bias to both the driver and the final amplifier are switched by +T. Despite some deliberate and undeliberate attempts, I've not managed to zing the final (probably because I have a spare). Harmonic suppression appears to be fairly insensitive to antenna impedance, which is characteristic of series trap suppression. R99 allows you to adjust the overall gain of the amplifier chain.

Mini'ceiver Construction

I feel that you will have a good chance of successfully building the mini'ceiver, or your customized version of it, if you are comfortable using a triggered oscilloscope in troubleshooting and have built several kits and scratch-built projects. Or, of course, if you can get help from a friend and/or someone in your club or repeater group with the above experience. I'm not trying to discourage anyone; I just want you to have a good chance for success if you embark on the project. Building and experimenting is great fun, and I want it to stay that way for you. I believe that you can build mini'ceiver for about $200, maybe less if you have a big junk box.

Parts

Photo D. Vfo construction detail.

ing of all major parts. As I promised, the parts are readily available. You might have a little trouble finding the NPO capacitors, but many radio-TV parts houses stock them. Keep in mind that one of your best sources for parts information is just a CQ or two away—just don't conduct your purchases directly on the air!

Chassis

I built my mini'ceiver in a 12" L × 7" W × 4" H Bud CU-3011A minibox, and used two 2¾" L × 2-1/8" W × 1-5/8" H Bud CU-3000A miniboxes within to house the vfo and bfo. As you can see in the construction photos, I put the power supply, receiver, speech amp, balanced modulator, and transmitter mixer on a main board and the transmit amp chain on a smaller piggyback board. This worked out successfully. However, I plan to use two cards of the same size mounted vertically, each facing out, in the next mini'ceiver. In this case, I would put most of the transmitter circuitry on one card. If you decide on this layout, keep the speech amplifier and final rf amp at opposite ends of the transmitter board!

Circuit Boards

The layout of high-gain rf and audio PC boards is something of an art form. For a one-shot project, it's hard to beat the use of single-sided (2-ounce copper) circuit board with the copper on the component side used as a ground plane. Notice that the transmit amplifier chain is built in this way. It's generally faster to duplicate a circuit using this approach than to go through the process of lifting circuit board art, exposing resist, etching, etc.

I've outlined the approach I like to use in an earlier article, but it's worth going through again. If nothing else, it makes component substitutions a snap. Get some drafting vellum with a light blue 1/10th-inch grid on it. After you have gathered all the parts for a circuit, you can begin developing the board layout. Start by mulling over the schematic and inspecting the components. Then lay out the components on the grid paper and think through their interconnection. Juggle the components around as needed for a neat arrangement that minimizes trace lengths and crossovers. If you think in terms of circuit strips, it makes things easier.

After you have the layout and interconnection for a section of the circuit visualized, pick up the components and sketch in their

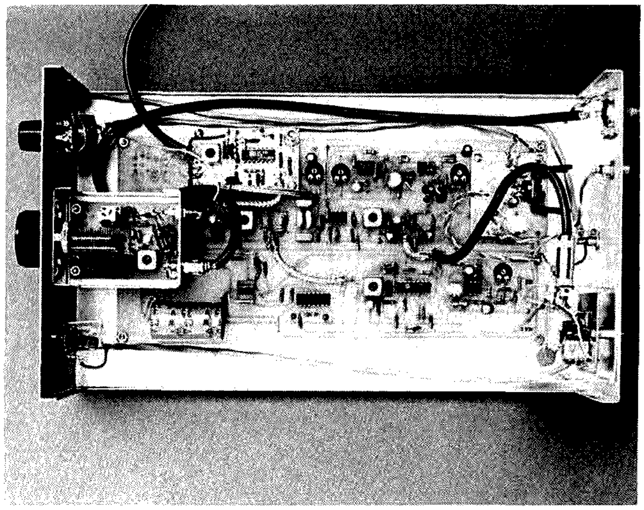

Photo E. View of the main board, which includes the receiver, speech amp, balanced modulator, and transmit mixer.

outlines on the vellum. Show the component interconnections underneath the circuit board with dotted lines. You will be surprised how fast this goes. Remember that all ground connections are on top. Be careful to keep input and output connections of high-gain rf and audio stages separated.

Once the layout is complete, you can tape it directly to your circuit board blank. Drill through the layout and the circuit board each place a component lead or wire goes through the board. I use about a #62 bit for most holes except IC leads, where I use a #68 bit. It's easy to enlarge holes later as needed for the bigger component leads.

After all the holes are drilled, lightly countersink them with a 3/32" bit—except those which are going to be direct ground connections. The countersinking keeps the leads from shorting out on the ground plane. After cleaning the board and perhaps tin-plating it, you can begin installing components. They are interconnected under the board by their leads and/or bus wire. Remember to keep connections as short as possible and watch input-output routing around high-gain stages.

Rf Coils and Transformers

Radio Shack currently markets a packet of magnet wire in three gauges: part number 278-1345. This type of wire can be stripped simply with hot solder, so it's ideal for rf coil and transformer applications. Use the 30-gauge wire for winding all the shielded transformers. Use the 22-gauge wire for winding all the toroids except L6 and L14, where the 26-gauge wire will be easier to use. I used a small 10-uH molded choke for L13. However, this should not be too critical. If you have trouble finding a molded choke, try 16 turns or so on an FT-50-61 ferrite core. It might be a good idea to put a 10-Ohm resistor in series with this choke to avoid any surprise resonances.

You will notice a number of bifilar windings are used. I use an electric drill to pretwist pairs of wires to about 6-8 turns per inch. Use an ohmmeter to figure out which wire is which after winding the bifilar coils. On the shielded coils, bring the bifilar pairs out together at each end of the bifilar winding and then separate and tin them under the circuit board. Don't try to solder directly to the coil-form posts on these transformers. You'll wind up a post short.

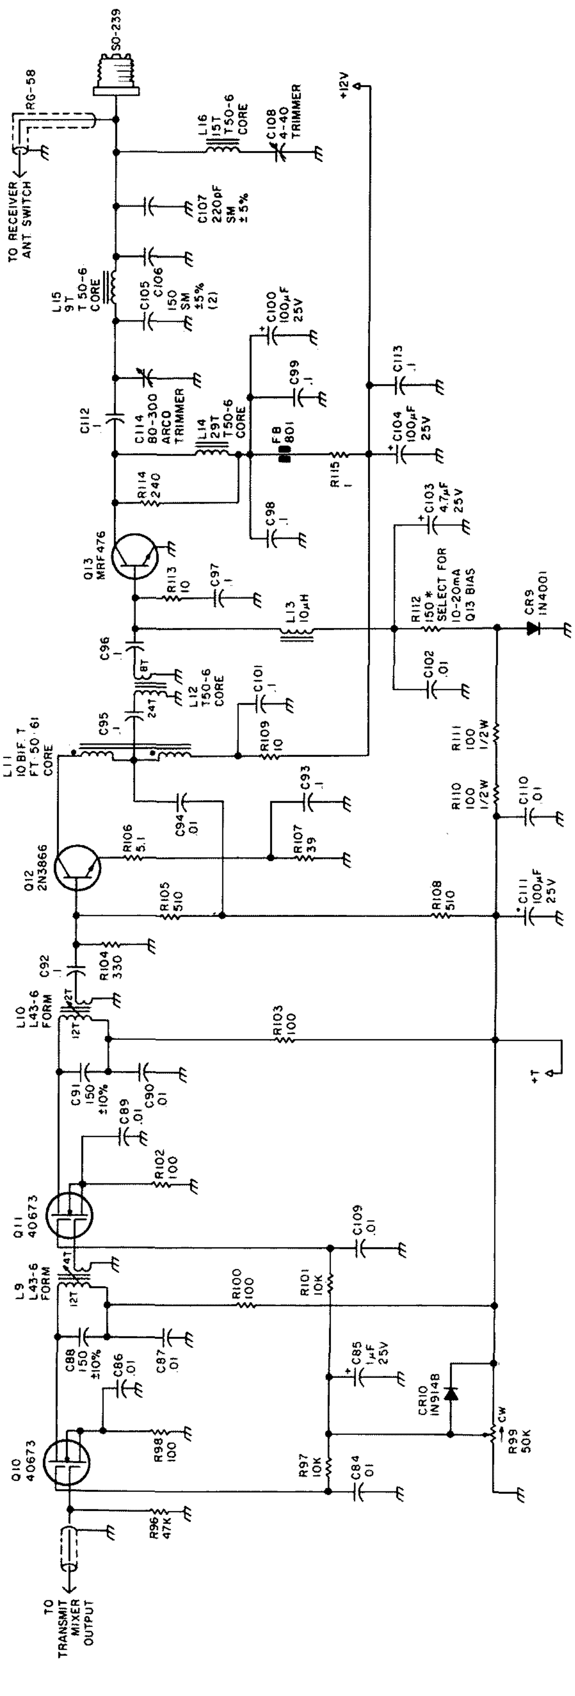

Fig. 7. Transmit-amplifier chain.

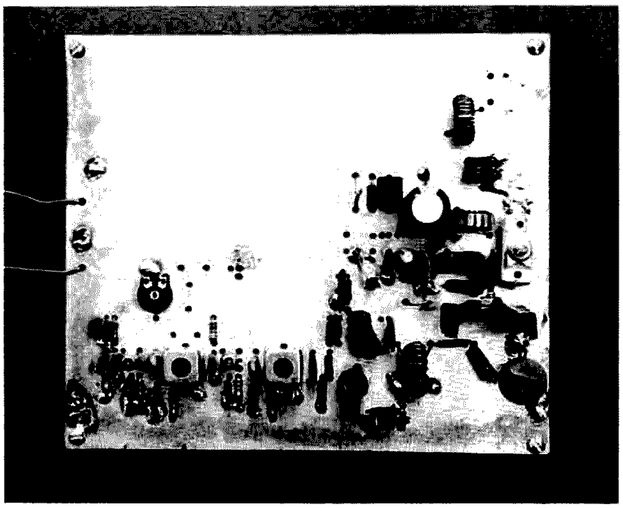

Photo F. Top view of the transmit amplifier chain. Note the "stovepipe" driver heat sink.

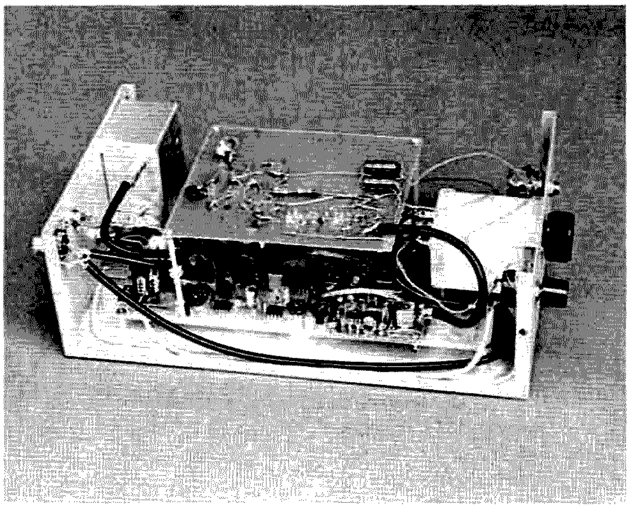

Photo G. Overall view of the mini'ceiver circuitry with the transmit amplifier card in place. The bfo is housed in the small minibox in the back.

You may find the vfo and bfo a little tight to construct since they have to fit in their respective miniboxes. With a little patience everything will fit. For the vfo, it's probably best to etch the copper off the circuit board except around the edges. Hopefully, the vfo detail photo will help with the layout.

Heat Sinks

The audio power amplifier, transmit final amplifier, and transmit driver should all have heat sinks. I made a "stovepipe" heat sink out of copper sheet for the 2N3866 driver. Standard commercial heat sinks were used elsewhere.

Tune-Up

Recommended test equipment for tuning up mini'ceiver includes a triggered oscilloscope with at least a 20-MHz bandwidth, a multiband HF transceiver, a dummy load, a frequency counter, and an audio oscillator. Luxury items for tune-up include a grid-dip oscillator, an rf signal generator with a step attenuator, a two-tone oscillator, and, of course, a spectrum analyzer.

Power Supply and T/R Voltages

You can run a mini'ceiver off a 12-V-dc, 1-A supply. Before powering up the rest of the circuitry, test the T/R voltage switch for proper action. Check the collectors of Q1 and Q2 in each PTT switch position for proper on/off action. You did wire the microphone jack up right, didn't you?

Bfo and Vfo Tune-Up

Apply +12 V dc to the vfo and check for oscillation with the scope at C16. Fully mesh tuning capacitor C9 and adjust C6 for operation around 5.250 MHz. Unmesh C9 and confirm operation at about 5.300 MHz. Set C9 about mid-range and peak L2 while looking at the vfo output. Then adjust R18, clockwise from the bottom, for a 5-V peak-to-peak output. Putting the top on the vfo will change its operating frequency somewhat, so you may want to tune and try a couple of times until you get it on frequency with the top on.

Apply +12 V dc to the bfo and back the slug nearly out of L3. While monitoring the output of L3 with the scope, slowly run the tuning slug in until oscillation starts. Peak the oscillator output. You should get about a 5-V peak-to-peak output. Check oscillation frequency with your counter and fine-tune the slug in L3 for operation at 8.998500 MHz. The bfo must be loaded with the product detector and balanced modulator for proper operation. It's a good idea to put a small hole in the top of the bfo minibox over L3 to allow for touch-up adjustment of the slug with the minibox top in place.

Receiver Tune-Up

Run the tuning slugs in on L4, L5, and L6 so that the tops of the slugs are just slightly above the top of the shield cans. Set the volume control and R47 at mid-range. You should now be able to hear 20-meter SSB signals on your antenna or on a 15' piece of wire stuck in the antenna jack.

Fire up your other HF rig into a dummy load at low output power and set its output frequency for about 14.275 MHz. Tune the mini'ceiver to find the signal. Once found, monitor pin 7 on IC4 (the agc output) and peak L4, L5, and L6 for maximum agc output. If you see the agc voltage peaking above 6 V dc during tuning, reduce your signal level a bit. You can now adjust R47 to suit. Back this pot down a bit if you run into high-volume audio distortion or instability when running off dry cells.

Transmitter Tune-Up

Hook mini'ceiver to a 50-Ohm dummy load. Short the PTT input on the mike jack to ground. Check the voltage across R115. It should be around 20 mV dc, which indicates a 20-mA quiescent bias on Q13. If it's much off this value, replace R112 with a larger or smaller resistor as needed to bring the bias in range. Incidentally, if you have trouble finding a 1-Ohm resistor for R115, you can use a 10-Ohm resistor (200 mV dc), but short the resistor out after setting up the bias.

Input a single audio tone of about 8 mV peak-to-peak into the audio side of the mike jack. Adjust R70 for a 1.5-V peak-to-peak audio signal at pin 1 of IC7. Hook the scope to the anode of CR8 and peak L7. You will see a waveform that looks like an AM signal with 20-40% modulation, about 400 mV peak-to-peak. Check pin 1 of IC8 for a fairly clean 150-200-mV CW signal. Look at the output of L8 and peak for a 14-MHz signal of about 150-200 mV. Move the scope to the output of L10 and peak L9, L10, and R99. Adjust R99 for a lower bias

voltage to Q10 and Q11 if the output of L10 is more than 500 mV peak-to-peak. Check the output of Q12 at C59 for about a 5-V peak-to-peak signal.

Hook the scope to the output of the amplifier chain (SO-239 connecter) and peak C114. This is broad tuning, so watch carefully. You should have about 25 V peak-to-peak of rf output. Find the 2nd harmonic of mini'ceiver's output on 10 meters and tune C108 for a null. Tuning is quite sharp, so tune carefully. C108 can also be tuned to peak the 2nd harmomic; be sure you tune for *minimum* output on 10 meters. You can use a short piece of wire for a receive antenna on your 10-meter rig since it's in the same room with mini'ceiver.

Disconnect the jumper and audio oscillator from the microphone jack and plug in the mike. Readjust R70 a bit, if needed, for an SSB voice signal similar to the one in Photo B. Be careful not to push too hard; there is enough flat-topping out there already.

Operation

Now the moment of truth. The results you get with mini'ceiver depend heavily on your antenna system, but this is true of any station. I think you will be surprised. I've gotten clean audio reports (except when I tried a narrower crystal filter!) and moderate signal strength reports which is expected for QRP. The fact that mini'ceiver is home-brewed does generate QSO interest.

Mods and Alternative Circuitry

An S-/rf-output meter can be added easily if you like to watch meters jiggle. For the S-meter, monitor the agc voltage which will vary from about 4 to 7 V. Add a 2:1 resistive divider across the rf output (about 1k total load) and then detect the peak rf voltage at the divider output with a diode-capacitor rf detector. This should give you about 6 V peak to drive the meter. Use a toggle switch to switch modes on the meter.

There is enough room left to add an "afterburner" if you feel you need a little more power. I suggest using an MRF477, which should take you easily into the 25-W range. No more lantern battery operation, though. The receiver antenna switch should be moved to the collector side of the matching network in this case. I don't suggest this unless you have already done some rf amplifier design.

Mini'ceiver should be fairly easy to put on other HF bands by adding the appropriate crystal oscillator and another 1496 mixer to achieve a suitable vfo output range, along with adjusting L and C values as needed.

From Here

You can never really finish an electronic design (or a computer program for that matter) and mini'ceiver is no exception. There are many ways the design can be improved. If you have an idea, try it! Experimenting is fun. If you would like to ask me a question about mini'ceiver, please send an SASE. 73! ■

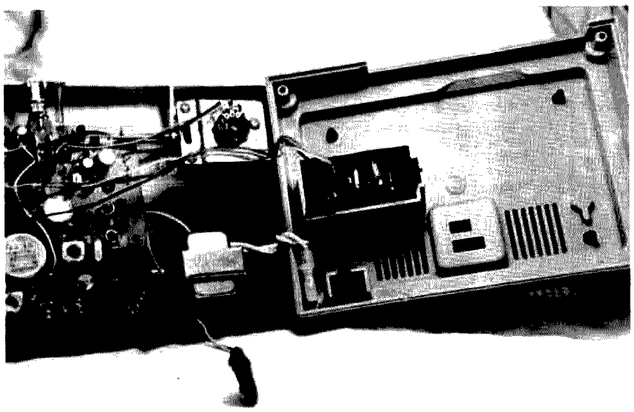
An Alarming Procedure

This false-proof repeater emergency alert won't tie up expensive equipment.

Melvyn G. Morris WA1LCF
Michael Polimer K1FNX
140 Hampton Road
Sharon MA 02067



Decoder board mounted in battery compartment.

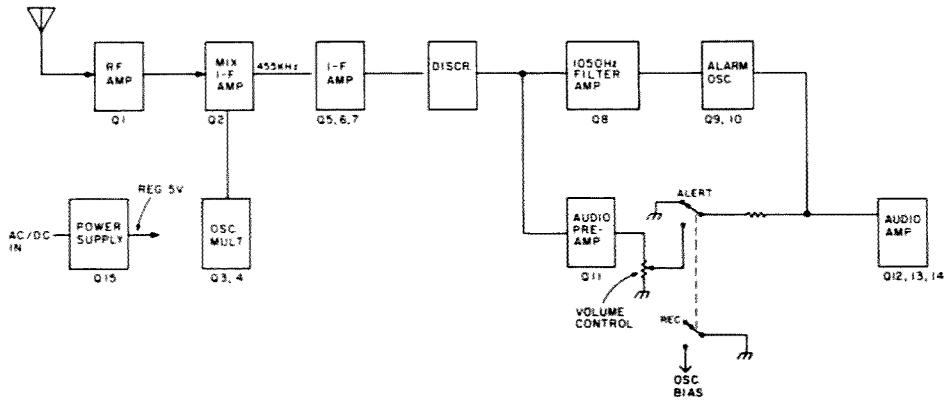


Fig. 1. Block diagram.

Two-meter repeaters provide reliable communication for relatively large areas surrounding the repeater site. There has long been a need for a reliable warning or alert system operating through a repeater for civil defense, RACES, emergency, and similar type requirements. In particular, if this need is required in the specific area within the locale of a repeater, then the approach described here-

in will prove more than satisfactory.

On the assumption that a secure alert signal must be coded in some way, it becomes readily apparent that the receiver/decoder must be immune (i.e., secure) from false triggering. The problems associated with using a repeater manifest themselves through the types of signals transmitted. For example: engine whine, noise, voice characteristics, whistling, and other distortions contained in speech must not falsely trigger the alarm mechanism. The receiver, therefore, must be of sufficient sensitivity to operate within a given signal-strength area and contain a decoder. The repeater must be able to pass the coded signal with sufficient amplitude to activate the alarm mechanism.

Additional requirements are that any operator can initiate the alarm without the necessity of a special code generator and that existing 2-meter receivers not be pressed into service to monitor and decode the alarm signals. (A previously published article out of Canada described the use of a 2-meter transceiver with a "listening" decoder placed in front of the speaker to receive and decode the alarm signal. Not only does this tie up a piece of very expensive equipment—but also it implies that the user must listen to every QSO and not forget to turn up the audio volume.) Finally, and above all, the receiver and code generator must be inexpensive.

With the rudimentary specifications as set forth above, a search was conducted into readily available equipment that could be modified for the task. After some deliberation it was decided that a crystal-controlled FM weather radio of the type used by mariners for monitoring NOAA

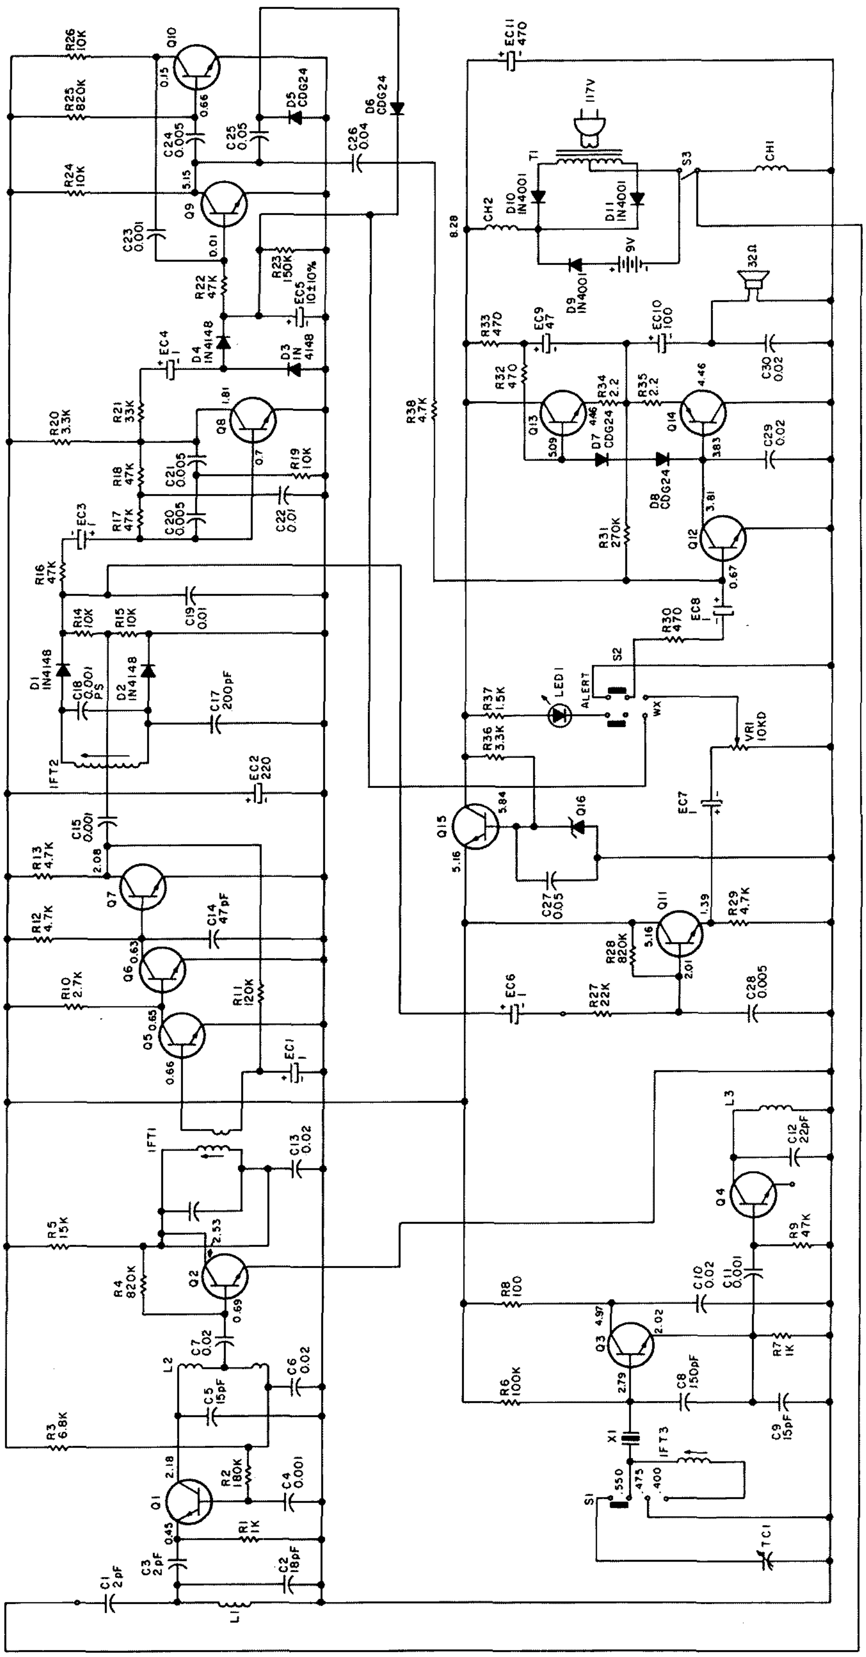

Fig. 2. Schematic diagram of unmodified Weatheradio.

weather broadcasts that also contains the built-in decoder for NOAA-broadcast weather alerts would be ideal. The Radio Shack Weatheradio Alert (catalogue #12-154) was selected and was used as the basis for design.

In the event of a weather emergency, NOAA transmits a tone (1050 Hz) which activates an alarm in the receiver which in turn alerts the listener to activate the audio portion of the receiver and listen to the detailed weather info. (Most weather-alert receivers allow the user to deactivate the audio while still keeping the receiver in the monitor mode.) Normally transmitted speech does not activate the system since a relatively long transmit time (seconds) is required of the coding signal and it is believed that NOAA also "notches out" 1050 Hz during non-coded transmissions.

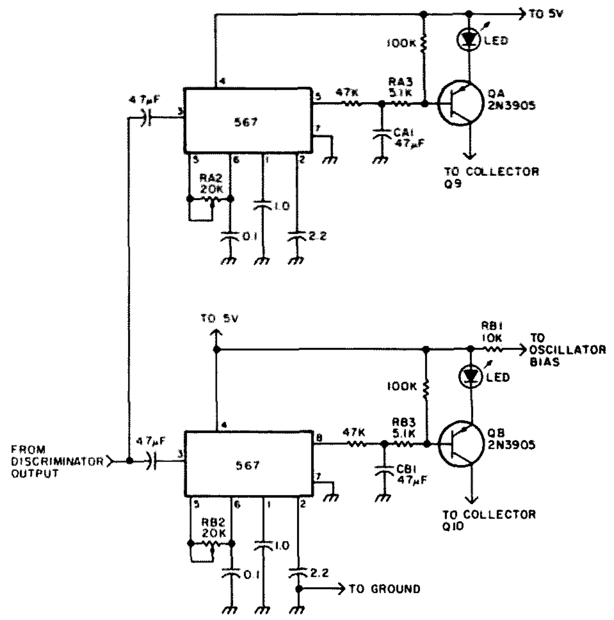

Fig. 3. Decoder subassembly schematic.

Before describing the modifications and design philosophy of our alert receiver, a cursory look at a simplified block diagram of the unmodified weather radio is necessary (Fig. 1).

The incoming rf is supplied (via a link to the ac power cord) to an rf amplifier. A crystal-controlled LO drives a diode multiplier and is loosely coupled to the input of a mixer stage. The output of the mixer (455 kHz) drives a tuned i-f amplifier and discriminator which provides detected audio to the audio preamplifier and to the 1050-Hz filter. In the normal listening (WX) mode the audio is boosted through the audio amplifier and drives the speaker. In the monitor (or alert) mode the alarm oscillator is enabled and the output of the volume control is disconnected from the audio amplifier and speaker. Reception of a 1050-Hz tone will trigger the oscillator and the signal thus produced will be amplified via the audio amplifier and sound the alert. (There are some auxiliary features which will be described in the discussion on modifications.)

NOAA broadcasts operate on frequencies of 162.400, 162.475, and 162.550. This is facilitated in the unmodified alarm receiver by operating the crystal padded with either a capacitor, an inductor, or nothing. A three-position switch on the rear of the unit is provided for this purpose. Since we will be operating on a fixed frequency, this is an unnecessary feature and must be disabled. (We set the switch in the "unpadded" position and epoxied it in place.)

The repeater frequency we are using is 146.865-MHz output. The rf stages must be retuned to this frequency as well as selecting a new crystal which will provide an i-f of 455 kHz when operating in conjunction with this frequency. A crystal frequency of 16.202 MHz is used to generate 455 kHz when operating with the "central" NOAA frequency of 162.475 MHz. Working backwards, 162.475 MHz −455 kHz = 162.02 MHz. It becomes obvious then that the multiplier is operating at a multiplication factor of 10. At the repeater operating frequency of 146.865, a crystal of (146.865 - 455 kHz)/10 = 14.641 MHz is required for the LO. (The crystal can be purchased from: Sentry Mfg. Co., Chickasha, Oklahoma: #SCM-18, HC-25/μ case with wire leads, 15-pF load.)

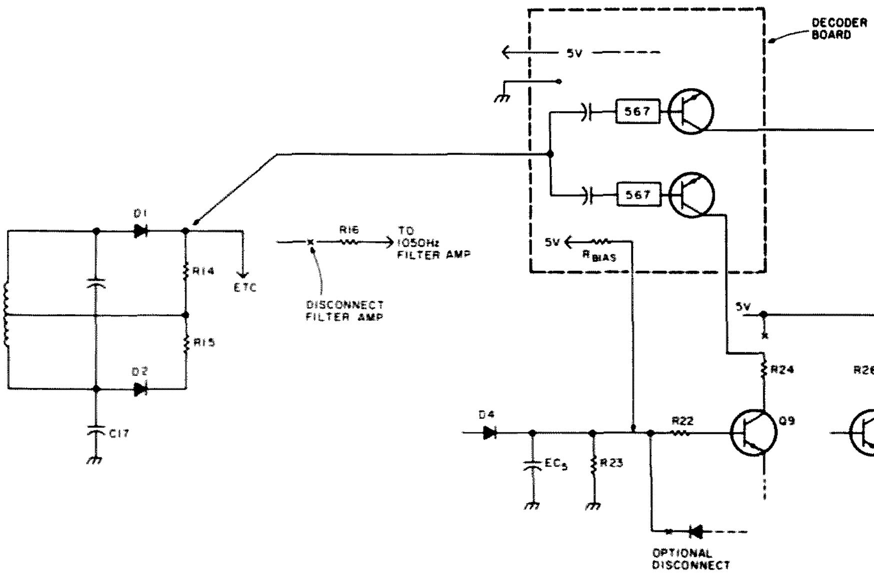

Fig. 4. Connecting the decoder board to the receiver.

With this determined and the planned use of the 1050-Hz coding signal, we set off to modify the receiver. First we applied a signal at the NOAA frequency of 162.475 MHz FM modulated with 1050 Hz (3-kHz deviation) and measured the output of the discriminator at the point where the alarm would just trigger. We observed the output of the signal generator and used this output (in microvolts) as the target sensitivity at the repeater frequency. On the trial unit this was observed as approximately 1 uV. Next we replaced the crystal, ob-

served that the LO was operating, and proceeded to retune the rf and LO stages. Unable to lower the tuned frequency adequately by squeezing the inductor coils closer together, we added capacitors in parallel to the tank circuits to bring the tuning in range of the coils. All the while we monitored the output of the discriminator and tuned for maximum output of the 1050-Hz signal. With judicious twisting and squeezing of the coils we were able to match the sensitivity observed at the NOAA frequency.

A hastily designed 1050-Hz tone generator was implemented and the receiver was put to the test. It triggered obediently in response to the coded signal—as well as from alternator whine and anybody who spoke with the right quantity of 1050-Hz energy! We quickly deduced that any decoding scheme that was dependent on a single frequency was doomed to a similar fate. In order to minimize the cost of the decoding circuitry, we decided against any scheme which required timing sequences. We also felt that the more complicated the scheme, the larger (and more costly) the decoder would be, and we did have space limitations within the receiver.

The solution decided upon was to code and decode a single two-tone composite signal much like that used in the Bell Touch-Tone™ system. In fact, for purposes of simplicity and availability, we designed around an actual DTMF tone pair. The 1050-Hz filter/amplifier was of no further use; therefore, it was bypassed. A small printed-circuit board containing the two tone decoders and their associated drivers was designed to fit into the backup battery compartment. (The backup battery would be glued to the receiver case using double-sided masking tape.) A detailed description of the electrical design and receiver modifications follows.

To understand how our decoder design developed, it is first necessary to understand the operation of the unmodified decoder-alarm circuit. Transistors Q9 and Q10 are operated as a triggered astable multivibrator. R22 and R23 keep the pair in an untriggered state by keeping Q9 off in the ab-

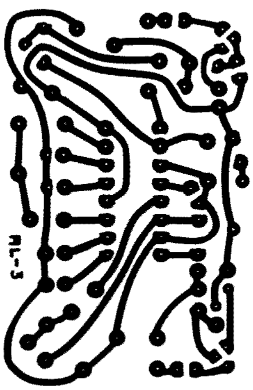

Fig. 5. PC board.

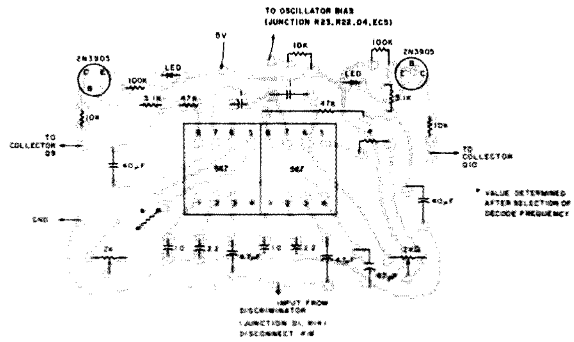

Fig. 6. Component layout. If resistors marked with asterisks are not used, they must be replaced by jumpers.

UNIVERSAL M-600 MULTI-MODE AND CRYPTO-DECODER

— NEW —
DECODES:

TOR-SITOR
BIT INVERSION
WEATHER FORMAT
NON STANDARD SHIFT

The M-600 converts these Codes plus RTTY (Baudot & ASCII) to video and will drive a Serial or Parallel printer for hard copy. Baudot speeds from 60 to 132 WPM and ASCII from 110 to 1200 Baud rates. Morse reception, auto range up to 60 WPM. The M-600 has 3 fixed shifts and 1 tunable shift. Multiple scroll inhibit and un-shift on space are included along with a built-in self-test system. Isolated loop MIL-188 or RS232 and optional parallel ASCII.

NOTE: Price, Specifications subject to change without notice and obligation

sence of any external bias current. When the coded 1050-Hz signal is received and passed through the 1050-Hz twin-T filter/amplifier (Q8), it is rectified and doubled via D3, D4, and EC4. The resulting dc is applied to the base of Q9 through R22 as a trigger current. The multivibrator then oscillates. Diode D6 rectifies the oscillator output and feeds it back to the input of Q9, thereby maintaining the alarm even after the initial trigger signal is removed. Depending on the desired mode of operation as an alert receiver, this may or may not be a desirable feature. This will be discussed later.

The two-tone-decoder design is a relatively straightforward adaptation of a standard NE567 design. Two decoders are connected in parallel and drive a pair of PNP trigger amps. In order to use as much of the existing receiver as possible, it was decided to disconnect the collectors of the multivibrator transistors from the supply rail and drive each of them from the tone decoders. In this way the oscillator cannot function unless both tones are present, thereby acting as an AND gate as well as an oscillator. The PNP trigger amps (Fig. 3) provide the necessary inversion of the 567 output as well as a convenient node to add some time delay to the decoding functions. (To prevent accidental triggering, a time delay was added to the decoding spec.)

Referring to Fig. 3, the output of either 567 (pin 8) goes low when the correct tone is presented to its input. This in turn provides bias current for the base of the PNP (QA or QB), but not until CA1, B1 is first discharged (providing the time delay). The LEDs in the emitters of the PNPs necessitate that the base drop an additional two diode drops (in addition to VBE) before the PNP can turn on again for time delay purposes. (They also add the additional feature of illuminating for test purposes.)

As mentioned above, when both PNPs are on, the multivibrator can oscillate. Note: Since the 1050-Hz filter/amp is disconnected, a permanently enabling bias voltage is applied to multivibrator transistor Q9 through RB1 on the decoder board. Potentiometers RA2 and RB2 permit tuning the tone decoders for the desired frequency. Refer to Fig. 4 for the modified schematic showing points of connection (and disconnection). Figs. 5 and 6 show the PC layout and an assembled board, respectively.

Some final comments are in order. We decided not to depend on rf coupled through the power line for our input. A banana jack was mounted on the case and connected to the rf input through a small capacitor. An inexpensive ¼-wave antenna was implemented using a piece of #10 electrical wire soldered into a banana plug.

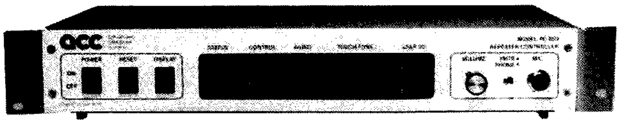
Also, for the needs of the Sharon, Massachusetts, Civil Defense group for whom this receiver was designed, the latching diode (D6) was disconnected. Our philosophy is that in time of civil emergency the intent of generating an alarm is to alert *available* personnel. If within the vicinity of the receiver, they will respond by switching to the audio mode and following the broadcast instructions coming over the repeater. If they are not around or available, latching the alarm will not serve any useful purpose. This is obviously a policy decision based on individual need.

One of the obvious advantages of this system is that any DTMF tone pair can be used. Using # or * has the advantage that they are not normally used tones in a repeater with a phone patch. If, however, it is felt that using known (and easily generated) tones can cause false alarms, then any pair can be used simply by designing simple multivibrator oscillators driving speakers and holding them against the microphone of a transmitter. Only authorized personnel would be issued coders.

The first prototype was built using perfboard and placed in continuous operation in the spring of 1980. As of this writing it has never "falsed" yet and continues to respond when needed upon adequate application (several seconds) of the coded tone pair. The unit is self-tested merely by unplugging and replugging the ac power by virtue of the momentary-charging current to the two time-delay capacitors, CA1 and CB1, applied through the base-emitter junction of the PNP drivers. That, by the way, is why the capacitors are connected to ground and not the supply rail, and why resistors RA3 and RB3 are required (to prevent burnout of the junctions).

One final comment: A more secure three-tone system is possible with no further modification of the receiver. Merely reconnect the 1050-Hz filter/amp (disconnecting the bias resistor RB1) and now a simultaneous three-tone signal (of which 1050 Hz is one) is necessary to trigger the alarm. Of course a proper three-tone generator would have to be designed. Other options are available if the filter frequency is altered from 1050 Hz.

We believe this design achieved our initial objective of providing a relatively inexpensive alert receiver wth minimal modifications and additions to an existing receiver. At the same time it did not require an elaborate code-generating device. It also does not require modifications to or need the use of other 2-meter equipment. ■



The New Standard in High Performance Repeater Control...

□ FRIENDLY, POWERFUL, EASY TO USE - Human engineered to be your "assistant" at the repeater, with capability second to none.

□ REMOTELY CONFIGURABLE - Change command codes, messages, tone characteristics, timing, and more, remotely! Reliable storage in E²PROM.

□ Room to grow: BUILT IN! - Features intelligent remote control and meter readback. Interfaces to synthesized remote bases and links. Planned software upgrade path.

□ SUPPORT - We invented the "Computer Controlled Talking Repeater," so we know how to provide the applications assistance, and long term support so crucial to a computer based product.

□ BRING YOUR REPEATER SYSTEM INTO THE 80'S - Starting at less than $1200!

The RC-850 Repeater Controller!

Call or write for detailed specifications.

Manual and demonstration cassette tapes available separately.

Trimming the Fat from ATV

Why use 3 MHz when 500 kHz will do? WB6FHD proposes a way.

My colleagues of the Southern California Amateur Television Club have been asking me to submit an extended article to *73 Magazine* since my brief presentation of this concept at our monthly club meeting, July, 1980, and its subsequent publication in our August newsletter. My purpose in publishing this article is to stimulate those of my radio amateur colleagues blest with true scientific creativity to develop this concept into a refined state-of-the-art system of global amateur radio television communication.

The development of a practical narrowband system of real television, in the true sense of the word, is of tremendous importance at this time, because every time we turn around, this or the other big commercial interest wants to lobby the FCC to give them portions of our amateur bands for their own private use, even though other amateurs in other countries still continue to use these same frequencies. My proposal not only will result in making it possible to transmit a picture almost similar in quality to a commercial televison station, but will do it in only one-twelfth of the usual channel bandwidth normally required. It will do this as low as six meters if we get together and petition the FCC with a proposal for experimental narrowband television privileges on the almost disused upper three-fourths of the band.

Another reason I want the experimentation to be on six meters is that occasionally there are some pretty good band openings into other countries.

I want to give thanks to Al Lipkin W3AEH, whose narrowband TV article in the 1964 ATV Experimenter Anthology (by *73 Magazine*) inspired me to carry his idea through the next few logical steps to the present engineering conceptualization of the entire system, all the way from camera to TV receiver. I sincerely hope that this article will start an avalanche of contributions by other engineers—as happened with SSTV exactly twenty years ago.

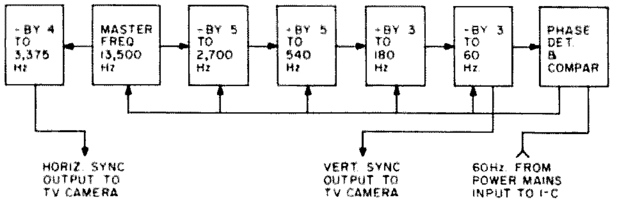

Fig. 1. The sync-generator countdown frequency-divider chain.

My profession is electronics-concepts design engineering, but I was caught in the aerospace layoffs of 1969 and have not been active in it since then. This means I am not up on the newest devices and technology, and accordingly will not submit any schematics.

The most interesting things about this proposal are that:

- The entire channel, video and sound combined, can be fitted into a bandwidth of only 500 kHz.
- The video and sound signals are generated independently, each crystal-controlled, both just above 10 MHz.
- Using simple SSB techniques (but no balanced modulator), the lower vestigial video sideband is completely filtered out, like an SSB signal, while retaining the carrier (for the present, but some day . . .?).
- The signal is now heterodyned from just above 10 MHz upward in frequency to the region between 51 and 54 MHz, where the maximum video modulating frequency will be less than one percent of the final transmitting carrier frequency, as with good engineering practice.
- The scanning standards will be: 225 lines per frame, 4:1 interlace, 15 frames per second, 60 fields per second, 56.25 lines per field.

The horizontal deflection frequency will be 3,375 Hz, and the vertical deflection frequency will be 60 Hz. The synchronizing pulses for the TV camera are generated by solid-state frequency divider-comparators and a phase-locked loop. The master frequency for the countdown (frequency-dividing) sequence will be 13,500 Hz.

To obtain the horizontal sync pulses, some of the master-frequency oscillator output goes to a divide-by-four device, output, 3,375 Hz. To obtain the vertical sync pulses, some of the master-frequency oscillator output (13,500 Hz) goes to a series of divide-by devices (see Fig. 1) resulting in an output of 60 Hz. This sync generator will provide the camera's modified horizontal and vertical sweep oscillator/amplifiers with the complex sync necessary to scan a 225-line, 4:1 interlace raster on the camera's vidicon image tube.

If the usual practice of ATVers is to be the case, this system will work fine, as there will be no discernible flicker if the motion in the image is not excessively rapid. We ATVers who use vidicon TV cameras know better than to either pan the camera quickly or go suddenly from a bright to a

dimly-illuminated scene, as we get smear in the image. The reduced horizontal scan rate will increase the vidicon's light sensitivity due to the photoelectric/photon-charge-storage principle, so an ordinary table lamp should suffice to light up the shack.

You might ask, why use only 225 lines in the image? Commercial television uses 525 lines; wouldn't the picture have less than half the sharpness, resolution, and detail of standard TV? Believe it or not, unless you have a huge screen and are almost sitting on the set, you probably won't even notice the difference. Have you seen how sharp the picture is on a 14" surveillance-camera monitor TV screen, or how crisp the detail is on your living room TV set when the kids are playing with the TV game? Those security systems and the TV games have one thing in common: The images are non-interlaced, and provide an image of only 262.5 lines on a security monitor or on any TV set.

I'm sure you're all wondering by now how a TV set can receive both a 525-line *and* 262.5-line image! Did you know that when your TV set is not receiving a signal, it is scanning only 262.5 lines on the screen? Whether or not you're receiving a signal, an interlaced signal or a non-interlaced signal, the TV set's scan oscillators don't change frequency. The 2:1 interlace system used in commercial television allows twice the number of scanning lines (and, therefore, vertical image detail) to be scanned by the TV camera than its scan-system oscillators, actually operating at no difference in frequency, would normally scan.

Whether the camera is scanning 262.5 lines or 525 lines, the maximum video frequency in the camera output is exactly the same. A 525-line non-interlaced picture would require a horizontal deflection frequency of twice that used for an interlaced system, and the maximum video frequency also would be twice that of an interlaced system. As for the difference between the 262.5-line picture which was discussed earlier and a 225-line picture, the difference amounts to only 37.5 lines—slightly noticeable, yes, but only if you had a 262.5-line picture being displayed on another TV set of the same screen size alongside.

In practice, a 14" screen is about the largest practical size for a 225-line TV system, and at a viewing distance of eight feet, no line structure can be resolved by the eye. The 4:1 interlace system outlined in this proposal consists of transmitting four coarse-scan fields, each consisting of 56.25 lines, in 1/15 of a second, to form a complete frame of 225 interlaced scanning lines.

The requirements for designing a 4:1 interlace system are as follows: The master frequency must end in a zero, and each divider stage downward in frequency must also end in a zero, all the way down to the mains-power frequency. The vertical scanning frequency must be the same as and lock to the mains-power frequency. The horizontal scanning frequency must be 1/4th of the master frequency, and end in the whole number five. The total number of lines comprising a frame, when divided by four, must end in the decimal .25 in the lines-per-field count.

Only a very limited number of different 4:1 interlace line-count systems which are mathematically possible are practical for a television system of this kind, and far fewer can be constructed to work, much less work reliably, if a relatively high frequency must be divided to a far lower frequency in just one device. This is because of these three big problems to be solved: stability, obtainability, and cost.

The following is for a 225-line-per-frame system with a 3×4 aspect ratio: The horizontal deflection frequency of 3,375 Hz is derived by multiplying the rate of frames per second (15) times the line count per frame (225). If the line-per-frame count is divided by four, we get the line-per-field count of 56.25, as four of these interleaved fields are scanned consecutively to form one complete frame. The usable lines and portions thereof for the image with any line-count or aspect-ratio scan system are approximately and on the average only 5/6ths of the total lines scanned, due to loss of lines during vertical retrace time, vertical and horizontal overscan on the camera image tube, and other scanning efficiency factors.

To calculate the maximum video frequency which will be produced by a television system, we first consider the aspect ratio (the ratio of height to width). In America, we use an aspect ratio of three units high to four units wide, or 3×4. Converting the 225-lines per frame to picture elements (pixels), we have 225 pixels vertically. As we have a 3×4 aspect ratio, 225 pixels is therefore only 3/4ths of what must be the horizontal pixel count; it follows that the horizontal pixel count is 300. The total number of pixels per frame, then, is 67,500, and multiplied times 15 frames per second is 1,012,500.

We must now divide this large number by 2, as at this point it must be understood that the maximum video frequency consists of alternate black and white squares on each scanning line, a black and white pair equaling one full cycle. When the video signal is closely examined, however, it is found that only the black (or only the white) squares count as the maximum measured video frequency. Therefore, 1,012,500 cycles divided by 2 is 506,250, and as we only have 5/6th efficiency, it follows that the maximum video frequency is 421,875 Hz.

For the sake of making things slightly easier, divide the product of total pixels times "rep-rate" by 2.4. (1.012,500 divided by 2.4 is 421,875.) Using the same system to calculate the maxium video frequency of a conventional commercial TV camera, 525 pixels × 700 pixels is 367, 500 pixels × 30 frames/second is 11,025,000 divided by 2.4 is 4,593,750 Hz.

In commercial practice, a filter limits the maximum video frequency to 4,000,000 Hz. As this 225-line system is incompatible with commercial television standards, it must be pointed out that commercial vacuum-tube TV camera and TV sets can be modified easily to a 225-line system, and what's more, I'll tell you just how to do it, too!

To begin with, the vertical deflection circuits in both TV cameras and TV sets aren't touched at all, as both systems are locked to 60 Hz. The TV camera conversion, first of all, must have the solid-state sync-generator board installed within, along with its power source. The horizontal-sweep circuitry will have to be modified from a frequency of 15,750 Hz to 3,375 Hz. If the vidicon won't fully scan horizontally, either more energy is required or the associated deflection coil hasn't enough inductance to give a good reactive load at this much lower deflection frequency.

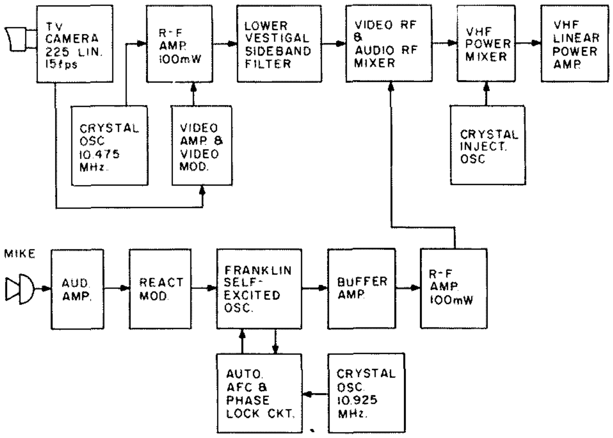

Fig. 2. The rf-generator video and audio-exciter chain.

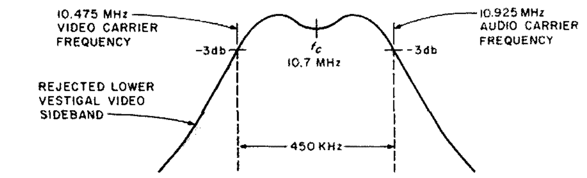

Fig. 3. The over-coupled, double-humped-response curve of the modified 10.7-MHz i-f transformer used in the output/filter circuit of the video-modulated rf amplifier.

Instead of the high-impedance horizontal-sweep tube, a silicon PNP transistor may have to be used, as its output impedance is low, and at 3,375 Hz it will be "looking into" a load which will be closer to a correct impedance match.

The receiver conversion will be fun. The horizontal-oscillator/amplifier circuit will continue to provide the picture tube with high voltage, but that's all. The afc circuit will be disconnected from both the horizontal oscillator and the horizontal-output transformer, and the horizontal deflection coils will be disconnected from the same transformer. A solid-state horizontal-oscillator/amplifier circuit will be built using the latest state-of-the-art phase-locked-loop technology to "lock the sync" even under adverse conditions of heavy QRM.

As with the TV camera, a silicon PNP transistor will likely be required to directly drive the horizontal-deflection coils. The metal case of the transistor will be grounded directly to the metal chassis of the TV set (and remember, the transistor's case is the collector) and the emitter will be connected to the sawtooth-scan side of the horizontal-deflection coils. The other end of the same coils will go to the plus side of the transistor's power supply. Since both the horizontal sweep frequency and the circuit impedances are now much lower than before, the diode damper normally required in the horizontal-output circuit should not be needed. Of course, the one in the high voltage power supply will naturally remain, as it is part of the "bootstrap" power supply associated with the high-voltage circuit to the picture tube.

An electron-beam squelching circuit will have to be added to put a dc voltage on the picture tube's electrode which blanks out the vertical retrace lines, because when no signal is being received to cause a fully 4:1 interlaced raster to appear on the screen, the free-running deflection circuits in the modified TV receiver will be scanning only 56.25 lines on the picture tube. This much-reduced scan of only one field will be intensely bright and will permanently damage the phosphorescent coating on the face of the picture tube with ugly brown horizontal streaks from which little or no useful light will come. Remember, 3,375-Hz horizontal-scan frequency divided by 60 Hz vertical-scan frequency equals 56.25 lines on the picture tube!

Now, on to the signal circuits. The TV set's tuner must have the swamping resistors removed to narrow down the band-pass to around 500 kHz. The channel 2 coils will be our concern here, as the signal coils will be centered between 51 and 54 MHz, say, 52.5 MHz. The oscillator will be modified to tune this range, but 23 MHz above. Why 23 MHz? Only the older TV sets had an i-f that low; all modern TV sets use 40-MHz i-f amplifiers! Well, first of all, the modern i-fs are twice as broad as we need, so they'll have to go—and be replaced with some Miller (or other) bifilar-wound 20-MHz i-f transformers, with best Q at around 23 MHz. All of the swamping resistors associated with the former i-f transformers are to be removed, of course. All of the i-fs will be tuned to the same frequency, not only for best gain, but with three i-f stages—optimum bandwidth, too. At the output of the last i-f stage, the bandpass should be around 500 kHz at −3 dB.

If it is desired to use an intercarrier sound-recovery system, it will operate on a frequency of 450 kHz, as this is the heterodyne difference frequency between the picture and sound carrier frequencies. 455 kHz i-f transformers will tune down here easily. The sound system is NBFM with plus and minus 5-kHz deviation. Another way to recover the sound is by using a low-band FM communications receiver made to tune below 30 MHz to the region between 22 and 24 MHz. The local oscillator should be converted from crystal control to self-excited, with the tuning control on the front panel. An afc circuit should be added to prevent drifting off center frequency.

Now we get to the *piece de resistance*, the rf generator. A block diagram is shown in Fig. 2. The video circuit will consist of a crystal-controlled oscillator driving a very low-powered amplifier with an output below 100 mW. This amplifier will be grid- or cathode-modulated by a video amplifier/modulator, supplied with composite negative-going video and sync by the modified TV camera. The output of the video-modulated amplifier will pass through a lower vestigial video-sideband filter composed of a large 10.7-MHz FM i-f transformer with overcoupled primary and secondary windings; this is in order to slightly broaden the bandpass and form the characteristic double-humped response curve.

Other components of the filter include a tunable 10.7-MHz series-T rejection trap, and a few crystals—in order to put a deep, wide notch just below the video-carrier frequency so that the lower vestigial video sideband will be completely filtered out. The video-carrier crystal oscillator will operate at a frequency of 10.475 MHz. The audio-carrier crystal oscillator will operate at a frequency of 10.925 MHz. These two frequencies are 450 kHz apart; both are sym-

metrically on opposite sides of the 10.7-MHz center frequency of the i-f transformer, and both, therefore, are the same number of dBs down on the transformer's response curve.

The FM audio signal's rf does not pass through the same i-f transformer used in the output/filter circuit of the video-modulated rf amplifier, but it will pass through a similar transformer in the output of the video rf/audio rf mixer. The 10.925-MHz FM audio generator will have one crystal oscillator and one afc phase-locked loop self-excited oscillator, both operating on the same frequency. The time constant of the afc/phase-lock circuit will allow for FM carrier deviation.

Now comes the rest of the answer to the question I'm sure all of you are asking by now, which is: Why does he keep harping on six meters? Doesn't he know that the FCC would never allow "that sort of thing," and hasn't he heard about the "national band-apportionment plan"? Well, I'll tell you, at the risk of sounding like some sort of rebel.

First of all, about FCC—how many of you can remember back when we could do anything we wanted to do on those ultra-shortwave bands? I do! As for this so-called national band-appointment plan, how many of you out there really agree wholeheartedly with how two meters and now 220 have been and are being chopped up into neat little slices for all of those open and closed machines?

Where are those "wide open spaces" we knew in the 40s and 50s where we had megacycles to burn? I know, I know—progress! OK, fine. Two things I know: A long time ago, I read somewhere that no one has a monopoly or right to any "personal" frequency in the "ham bands"—and I've got a box full of crystals for six and two meters and I guess a lot of them must fall across repeater-band edges and outputs!

'Nuff said? I think so, too, so let's get back to business. By now, at least a few of you must be wanting to say, Hey! How can a country with a different mains-power frequency than ours send us a picture with a 50-Hz vertical-deflection frequency and some cockamamie horizontal frequency and we receive it?

That's easy! All you have to do is remember that your TV set doesn't care what it gets—just design enough latitude into your horizontal and vertical hold controls and their phase-locked-loop circuits, and you can reach out and hold on to the "man in the moon"!

Next question: How about color? Thought you'd never ask!

Let's get black and white off the ground first (!) but, since you won't get any sleep unless I tell you, here goes. Yes, of course, the present American or European systems can be converted to work with my system. The TV receiver should have many adjustments (like a scope) so that any scan system, type, and polarity of sync or modulation can be received. Incidentally, I've got another, even narrower-band system of real TV which I can tell you about. It would fit into an FM channel. Of course, it wouldn't have nearly the definition or quality of what I'm offering you here. However, I'll give you one more hint. It would be like slow scan, but real TV. Cheerio! ■

WHEN YOU NEED JUST A LITTLE MORE AUDIO

The FASTRAK® model 2003 audio amplifier module produces 250 mW of low THD audio. This transformerless design has a low parts count and does not require a heatsink.

The model 2003 features a dc-operated volume control. Output level is selected by changing a dc voltage with an on-board pot, remote pot or micro-computer D/A interface.

- Low-Z, ac-coupled output drives speaker or headphones.
- Dc-type volume control assures hum-free operation without using shielded cable to the volume control.
- No interstage transformers or heatsinks.
- Compatible with other FASTRAK® modules, such as the model 2002 sound synthesizer.
- One evening assembly using 3.6 by 1.0 inch pc board and instructions supplied.
- Price: $9.45

Price includes: glass-epoxy, etched, plated, drilled pc board; instruction manual; postage in U.S.A. (Ohio residents add 5% sales tax).

Send $1.00 for illustrated FASTRAK® product catalog and refund coupon.

The Forgetful Autodialer Puzzle

Even Sherlock couldn't figure out how to make an autodialer that reprograms with no hardware changes. Elementary, says dear Batie.

Howard F. Batie W7BBX
12002 Cheviot Drive
Herndon VA 22070

Photo A.

Among some autodialer designs for 2-meter mobile autopatch use, a common limitation has been a lack of programming flexibility.[1,2,3] Although it is much easier to design and implement a diode-logic or PROM scheme for storing phone numbers, changing or adding a telephone number can be quite inconvenient for hard-wired systems or PROM-based designs. In this design, programming is done directly from the tone-encoder keyboard and allows programming of up to eight phone numbers. Numbers which are not programmed can be dialed directly from the keyboard in the normal manner.

The primary disadvantage of a RAM-based design is the requirement to continuously power the RAM to overcome its volatility. However, when you consider that an ample power source is available at both places in which an autodialer has a real application (your car and the shack), the disadvantage is more than offset by the ability to reprogram the memories very quickly and easily. Since the circuit described here has a total continuous current drain of only about 45 mA from a 12–15-volt source, it may be connected directly to the car battery without fear of running it down, since cars usually do not sit idle for weeks at a time. If complete disconnection is necessary, each phone number can be reprogrammed as quickly as the phone number can be manually dialed.

The RAM used was carefully selected after considering all available CMOS and bipolar memories; the logic support circuitry was then designed to meet the needs of the RAM. The most important constraints were that the RAM have bidirectional input/output lines and that these lines be tri-state. These requirements were necessary in order to significantly reduce the circuit complexity and cost while still permitting the keyboard to be used manually without affecting the stored phone numbers. Of secondary importance, it was desired that the RAM

be organized 8 bits wide to allow direct interface with the seven data lines of a 3×4 keyboard matrix. The RAM selected was the Texas Instruments TMS 4036 since it met all of these requirements.

Description

Fig. 1 shows the complete autodialer schematic; connections to the transceiver are shown in Fig. 2. The autodialer memory holds up to eight numbers of up to seven digits each (* and # count as digits); therefore, the number actually stored may be either a standard 7-digit telephone number or an autopatch access code of from 1 to 7 digits in length. The total number of phone numbers in memory is a function of the RAM organization, in this case 64×8. With selection of a different RAM, more or fewer telephone numbers could be stored. For example, if the RAM organization were 128×8, sixteen phone numbers could be stored. Eight 8-bit words are required to completely store each 7-digit telephone number.

Inclusion of D2 and D3 drops the voltage supplied to the RAM from +5.0 volts down to about +3.5 volts. This decreases the current required by the entire autodialer from 65 mA to about 40-45 mA. Reliable data retention is maintained with this RAM as long as the Vcc pin remains above +2.8 volts dc.

In addition to direct programming from the encoder keyboard, other features of the autodialer include a speed control to vary the rate of readout, an onboard audio amplifier to allow you to hear the tones sent to the transceiver, a visual indication to aid in both programming and readout, and a minimum number of controls. The autodialer may also be used as a "standard" tone encoder to manually dial

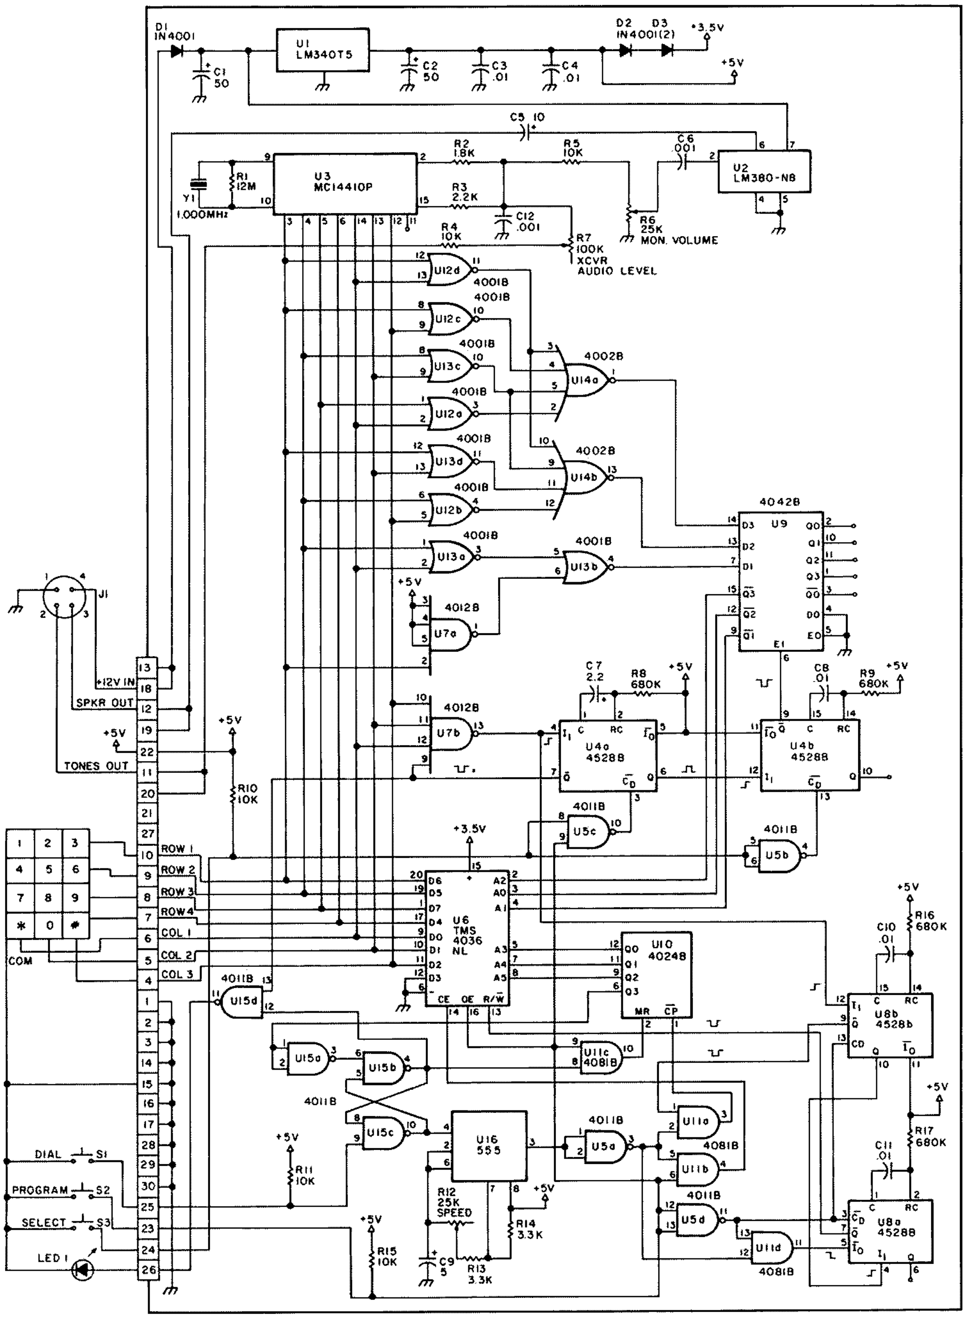

Fig. 1. Schematic diagram.

phone numbers or access codes which are not programmed directly into the memories.

Operation

Selection of one of the eight stored phone numbers is accomplished by depressing the appropriate keyboard digit (1-8) while holding down the SELECT push-button, S3. This action latches the logic state of three RAM address lines (A0, A1, and A2), and is used to select the desired phone number location for either autodial readout or programming. The selected phone number will then be available until a new one is selected; neither manual operation of the keyboard nor autodialing the stored phone number will alter the selection of the phone number.

To program the autodialer, the phone number digits are keyed in on the tone encoder keyboard with the PROGRAM push-button, S2, held down. This action routes the U8b output pulse produced by each keyboard digit depression to the clock input of the counter, U10. When each digit key is depressed, LED1 will light for about half a second; when it goes out,

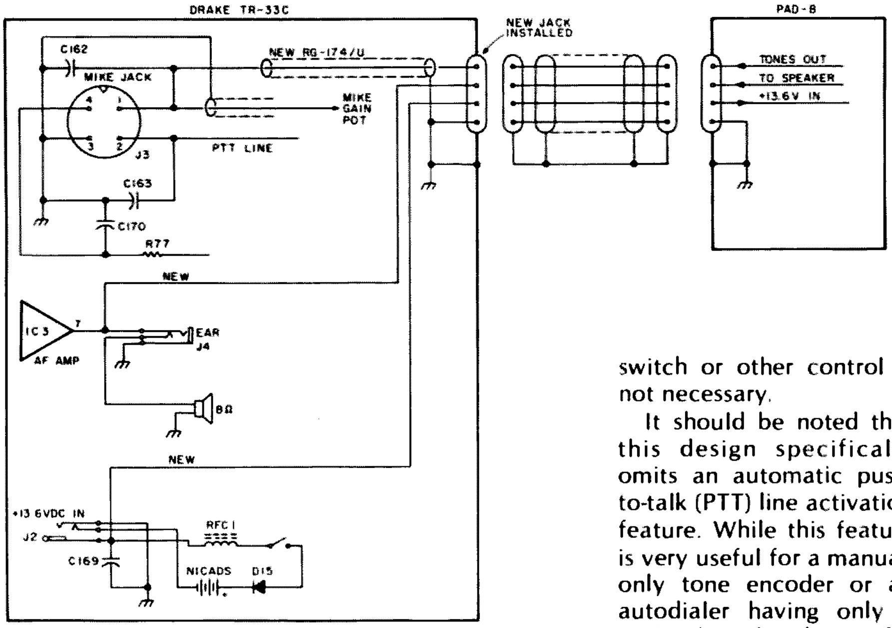

Fig. 2. Typical transceiver connection detail.

that digit has been programmed in and the next digit may be programmed. If only four digits are to be programmed (as in an access code), they are keyed in in the same manner.

Then, after the last digit has been entered, tap the DIAL push-button, S1, while keeping the PROGRAM button down. This activates the clock and steps the address counter, U10, through the remaining memory addresses for the selected phone number. Whatever information may have been stored previously in the latter part of the 8-digit memory segment is automatically erased. The LED will light up while the clock cycles through the unused digits; when it goes out (or when all the digits have been entered into the memory), release the PROGRAM push-button, and the memory is ready to be autodialed.

To read out (autodial) a phone number, simply select the phone number you want and press the DIAL push-button, S1. LED1 will light up during the autodialing sequence; when it goes out, the number has been completely autodialed.

In the manual mode, the tri-state memory data lines are always in the high-impedance OFF state; the keyboard activates the tone encoder, U3, and the encoder tones are fed directly to the transmitter mike input. Since the autodialer is always ready to dial a phone number manually (except when programming or during autodial readout), a separate manual/autodial switch or other control is not necessary.

It should be noted that this design specifically omits an automatic push-to-talk (PTT) line activation feature. While this feature is very useful for a manual-only tone encoder or an autodialer having only a PROM-based scheme for storage of phone numbers, incorporation into a keyboard-programmable autodialer based on a RAM design is actually undesirable. In a ROM-based scheme, the manual keyboard is used only for dialing unprogrammed numbers; however, in a keyboard-programmable RAM-based scheme such as this one, the keyboard serves two additional functions—selection of the phone number to be autodialed and programming of the actual digits. This also eliminates panel clutter by making additional controls unnecessary. Inclusion of the automatic PTT feature on a keyboard-programmable autodialer would activate the transmitter when selecting or programming a phone number. This is undesirable and was avoided, allowing off-the-air phone number selection, programming, and autodial readout monitoring. The microphone PTT switch is used in the normal manner to key the transceiver for both speaking and for autodialing.

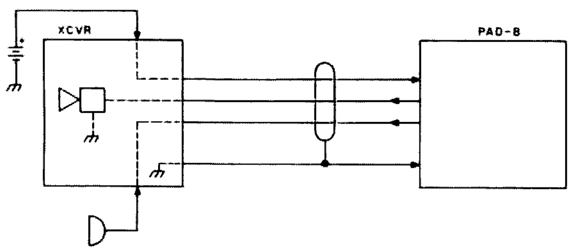

Fig. 3. Connection as shown for Fig. 2. Power is derived from transceiver and transceiver speaker is used for monitor.

Construction

A conscious effort was made to keep the overall size of the finished autodialer to the minimum necessary, so that installation in the car would not be hampered by a bulky cabinet. A large and expensive multideck rotary switch for phone number selection was eliminated from an earlier design, as was an internal monitor speaker. The final PC board design and layout now incorporates keyboard-selection of the phone numbers and still retains the on-board audio amplifier to permit monitoring the encoder tones in the speaker of your transceiver.

The requirement for bulky panel controls in an earlier project[4] has been eliminated by incorporating the panel control functions within the logic design. The result is a very compact unit which retains all the necessary features. A standard LMB enclosure (CR-531) was chosen, based on its small size and neat appearance, and the PC board was laid out to conform to it.

The PC board itself measures 2½" × 5¼" (6.35 cm × 13.34 cm), is of top-quality commercial-grade G-10/FR-4 material, is double-sided with plated-through holes, and contains all of the components required except the three panel push-buttons, the input/output jack, and the LED. Connection to all panel controls is eased by providing all required logic and power signals to a central location on the PC board; a ribbon cable can then be used to interconnect the PC board with the panel controls. All panel, signal, and panel-control lines are also available at the dual, 15-pin edge-connector fingers on the PC board (0.156"/3.96 mm spacing). By laying out the PC board in this fashion, maximum flexibility is afforded for selection of any convenient-sized cabinet or, if desired, the panel controls can be remoted entirely from the autodialer PC board through an edge connector.

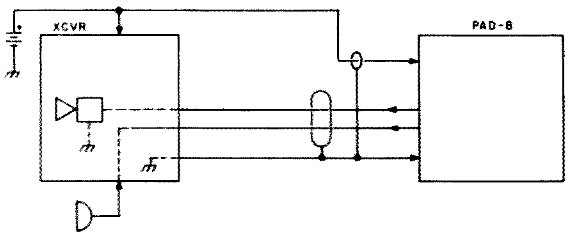

Fig. 4. Autodialer power is derived directly from car battery; transceiver speaker is used for monitor.

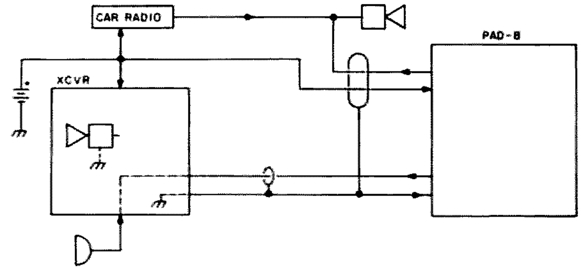

Fig. 5. Autodialer power is derived directly from car battery; car radio speaker is used for monitor.

Installation and Adjustment

Autodialer interconnections to your 2-meter transceiver include the +13.6-volt supply line, tone encoder output, and the audio amplifier output; these should be shielded between the autodialer and transceiver as shown in Fig. 2. The TONE jack on the rear of my Drake TR-33C was replaced with an audio DIN jack. Although a six-pin jack was used (for possible future access to other parts of the transceiver), only the three lines mentioned above plus ground are required by the autodialer.

The supply line can be run to a +13.6-volt source separate from the transceiver, if desired, permitting use of a standard 2-wire shielded mike case between the autodialer and transceiver. The autodialer tone-encoder output is extended through a short piece of RG-174/U to the transceiver microphone jack; the coax shield need not be grounded at the mike-jack end. The audio amplifier, U2, is connected directly to the transceiver speaker; normal transceiver audio is not affected and this arrangement eliminates the need for a separate speaker. The wire to the speaker inside the transceiver cabinet need not be shielded. The tone encoder output can be interfaced directly with either low-impedance microphone inputs (e.g., TR-33C) or with high-impedance inputs (e.g., the Heath HW-2036A).

Only three adjustments are necessary for proper operation of the autodialer. The speed is set by R12 to give a total autodial duration of about one second for all seven digits. The tone encoder output level into the transceiver microphone input is adjustable by R7. If a deviation meter is available, the tone-encoder output may be set to yield a deviation of about 4.5 kHz when any keyboard digit is held down.

Alternatively, the level may be adjusted by ear with the help of another operator on the repeater to a point which gives reliable autopatch access and dialing operation but which does not sound distorted (over deviated). The last adjustment is to set the audio-amplifier output level to give a comfortable and undistorted speaker volume under road conditions. R7 is the trimmer which does this. If the external audio monitor is not desired, R5, R6, C5, C6, and U2 can be eliminated altogether.

Final Notes

The addition of the autodialer described here has made a great improvement in the ease and enjoyment of using the local autopatch repeaters and has certainly decreased the risk of becoming a potential traffic statistic while trying to dial a phone number. Further, the ability to rapidly and conveniently program or reprogram phone numbers in the memories is greatly appreciated, especially when access codes are changed periodically. In addition, performance of the autodialer has been absolutely flawless throughout three very cold winters and hot summers, and I'm looking forward to many more years of enjoyable repeater autopatch use with this autodialer.

The printed-circuit board for this project and a 10-page illustrated step-by-step assembly manual are available from me for $10.00 postpaid in the US. I'll be happy to answer questions about the autodialer, but please include an SASE. ■

My Own Silver Mine

For W1FLP, reclaiming silver from photographic fixer is cheap, easy, and profitable. King Midas should have had it so good.

I recently purchased a brand spanking new Azden 2m rig. As I was installing it in the mobile, I came to the realization that my total cost was $2.50—yes, that is correct—two dollars and fifty cents! No, it was not "hot!" I paid a local dealer full list price.

Knowing that many brother hams are also amateur photographers, I thought they might have an interest in how to obtain goodies for the shack at a relatively low cost. The secret is in silver reclamation.

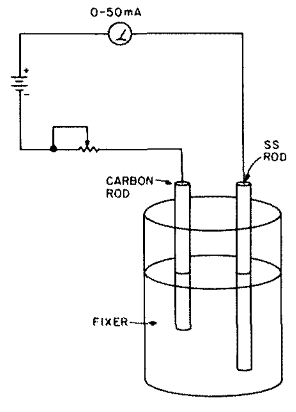

Fig. 1. Typical electrolysis circuit.

Silver reclamation is generally thought to require expensive capital equipment and in large photo labs it does, but for the amateur, the equipment can be very simple. How simple is determined by the amount of silver-saturated solution you have, how rapidly you obtain it, and how fast you want to reclaim it.

The silver-saturated solution referred to is the photographic fixer in every darkroom. The process of fixing photographic film removes the unexposed silver crystals from the film. This silver remains in solution in the fixer. The more film processed, the more silver in solution.

With the price of silver what it is, it doesn't take much math to find the "break-even" point at which investment in capital equipment is desirable.

For hams, using their innate ability to scavenge junk boxes to produce working apparatus, there is an inexpensive, easy method to reclaim impressive amounts of silver at very low cost.

The method I use is electrolysis. Basically, it is accomplished by passing a current (dc) through the solution, thereby "plating" out the silver. Industrial concerns use large containers with large currents and constant circulation of the solution.

I will not get into the math required to determine the current and voltages; the important parameter is the current density required to reclaim 90% to 98% pure silver. The current density needed is determined by the amount of silver in solution, the surface area of the electrodes, and the level of circulation of the solution. A typical electrolysis circuit is shown in Fig. 1.

Any dc supply can be used; regulation is not required. A simple half-wave rectifier without filtering will do fine.

The simple system I use is a 1.5-V alkaline battery, a potentiometer, a 0-50 mA dc meter, a stainless steel rod, and a carbon rod. The 1.5-V battery and the pot can be replaced by any available power supply, with an increase in the cost of silver recovery.

When a dc current is passed through the solution, the silver is plated out onto the stainless steel rod.

It is important to monitor this plating process until you arrive at the correct dc current (current density) for your individual setup. The plated silver should appear white to light cream-colored. If it appears dark cream to brown, the current density is too high. A darker color means that higher amounts of contaminants are being plated out.

Reduce the current. The color changes can be seen in seconds, so if it has not been dark for more than a few minutes, no harm has been done.

High current densities without circulation of the solution will result in lowered purity of the plated-out silver plus a chemical change in the fixer that will reduce the amount of silver you can reclaim.

When the silver has built up to a thickness of between 1/8 inch to 1/4 inch, remove the stainless steel bar holding the silver, rinse it in warm water, and let it dry.

To remove the silver, spread out a plastic or paper sheet, strike the plating sharply with a screwdriver, and it will crack. Simply chip off the plating until it is all removed. Return the stainless steel bar to the silver mine and continue.

Of course, this mine is not bottomless. The fixer solution will eventually become so low in silver content that it must be replaced with fresh solution. Fresh solution, in this case, means solution that has been used to process film and is no longer useful for fixing film because it is saturated with silver.

There are many methods to determine the useful plating life, i.e., silver content, of the fixer. The easiest but least accurate is the color of the solution. When it turns the color of medium strength tea, replace it. The more accurate method is to use the Kodak Silver Estimating Test Papers, cat. no. 1965466. When dipped in the solution, this test paper will turn from its normal yellow to some shade of brown. The darker the color, the higher the silver content remaining in solution. There is a color comparison chart on the back of the Kodak folder. I generally discard the fixer at a remaining silver level of 1 gram/liter.

To set up this simple silver mine, I used a carbon rod from a discarded D-cell battery, a 6-inch stainless steel rod, a 1-lb. plastic margarine container, and a battery, pot, and meter as previously described.

With no agitation of the solution, I maintain a current of 5 mA. I have been plating out approximately 3 ounces troy of silver per month. I am blessed with the availability of 12 gallons of fixer every 12 weeks that has a silver content of approximately 10 grams/liter. The amount of silver you recover per liter will depend upon its starting silver content, i.e., how much film has been processed through it and the average image content of the film.

The effect of the film image on silver content is that a very dark image has most of the silver left in the film. Conversely, a light image has had most of the silver removed. The Kodak test papers can be used to determine this silver content and, barring the probable contamination of the fixer with other chemicals, can be used as a guide to the useful life of the fixer.

The above method requires monitoring but twice daily and fixer replacement when required. If you have plenty of fixer and/or want a faster recovery rate, simply provide a means of gentle agitation. I have successfully used an old clock motor with a plastic shaft with a ½-inch by 2-inch paddle connected to the sweep second-hand shaft immersed in the fixer. This has yielded about an ounce a week. Larger electrodes, higher currents, greater agitation, and larger solution containers will of course increase the recovery rate.

So why throw good money down the drain? Dig into that silver mine and buy some more ham gear. ■

Fun-Equipment Revisited

Here are higher-band versions of the ever-popular Fun-Mitter and Fun-Amp. They are based on the Fun-Philosophy: cheap and simple.

Mark Oman WA0RBR
528 Deines Court
Ft. Collins CO 80525

Home-brewing is alive and well! I reached this conclusion following the response to the publication of my series of "Fun" home-brew gear.[1-4] Response to the simple, low-cost home-brew units has been great, indicating that hams are still building at least some of their own gear. From nearly-Novices to long-time Extras, hams have built the Fun rigs and have discovered that building is easy, fun, and very rewarding.

Many requests have been received asking for different band coverage of the Fun-Mitter and its companions. This article is the result of those requests. It describes a simple CW transmitter for 15 or 20 meters operating off 24 volts and modification of the 20-Watt Fun-Amp for operation on the same bands.

The Fun-Ceiver and Fun-Oscillator are not included in this article on modifications due to instability problems at higher frequencies. Frequency stability is of prime importance with today's rigs and it is just too difficult to obtain the type of results desired on the higher frequencies and still maintain the objectives of the gear.

This second version of the Fun-Mitter is a five-Watt-output, crystal-controlled CW transmitter that uses either low-cost FT243 crystals at one-third the operating frequency or HC6U fundamental crystals on the operating frequency. If the variable crystal oscillator (vxo) capacitor is installed (C option), the frequency can be varied by as much as 10 kHz from the crystal frequency, using HC6U crystals.

This coverage allows enough flexibility to provide plenty of frequencies with only a few crystals. Crystals are cheap, easy to obtain, reliable, and very stable. They make simple transmitters easy for all of us to build!

Philosophy

An early objective with the Fun-Mitter and Fun-Amp was to design simple gear that was easy to build with parts that could be obtained from Radio Shack. The Mark II versions of these rigs follow the same objective with only the crystal and its socket not being found at Radio Shack. Other objectives: costs of less than $25 each, no tuning adjustments, and same size PC boards (2¼" × 3").

These objectives are continued in the higher-band versions. A twenty-meter transmitter and amplifier can easily be built in an afternoon and put on the air without adjustments. (The reader is strongly urged to review the articles on the Fun-Mitter and Fun-Amp for detailed construction and design descriptions.)

Circuit

The circuits remain unchanged from the original designs. The resonant circuit and filter values, however, must be changed to allow operation on the higher frequencies. Radio Shack rf chokes and disc ceramic capacitors again were used.

The Fun-Mitter schematic is reproduced in Fig. 1. The Pierce oscillator operates on the operating frequency using either third overtone or fundamental crystals. (A third overtone is simply three times the value marked on the crystal.) For example, to operate the transmitter on 14.060 MHz, either a 14.060-MHz fundamental crystal can be used or a 4.383-MHz crystal can be operated on its third overtone. (This allows the use of cheaper FT243 crystals in the Fun-Mitter.) Also, on fifteen meters many of the same crystals used for forty meters, when operating on their third overtone, will provide the frequency coverage desired.

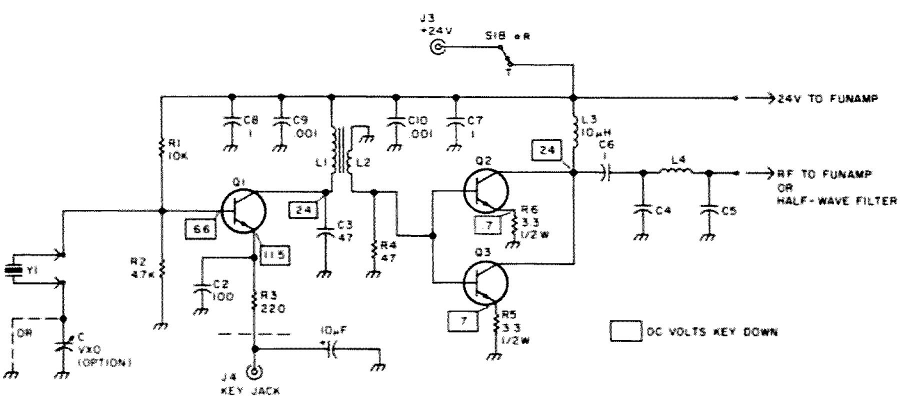

Fig. 1. Schematic of 15/20-meter Fun-Mitter. Reference designators remain the same as in the original Fun-Mitter article in order to match the parts locator for the PC board. Capacitance values less than 1 are in uF.

Fundamental mode crystals in an HC6U holder do, however, have the advantage of more frequency range when used with the vxo capacitor (C option). I have had several HC6U crystals, however, that do not provide a stable, clean oscil-

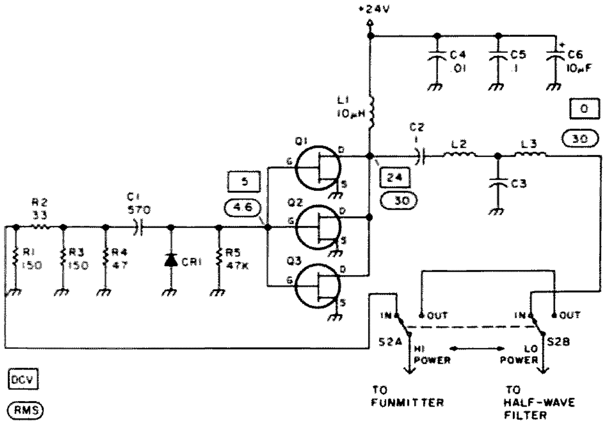

Fig. 2. Schematic of 15/20-meter Fun-Amp.

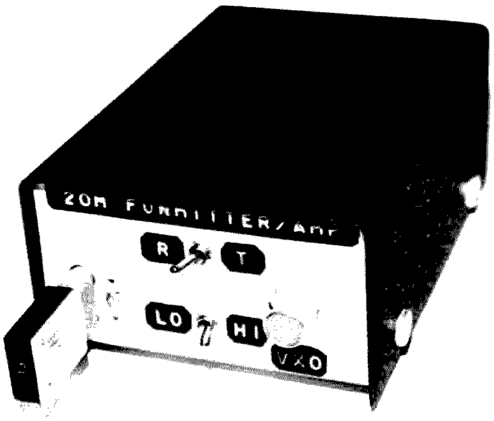

lator signal, probably due to the higher-than-normal power used in the Fun-Mitter oscillator stage. Although the FT243 will have a range of only approximately 1 kHz with the vxo, it will provide better and more reliable operation. (FT243 4.3- or 7-MHz crystals for use on twenty or fifteen third overtone will not oscillate on exactly three times the marked frequency. Depending on the crystal, they may be as much as 10 kHz lower than the marked frequency. Keep this in mind when ordering.)

L1 and C3 determine the resonant frequency of the oscillator. If L1 is constructed correctly, the oscillator should oscillate with no adjustments. A three-turn winding (L2) over L1 operates as a transformer to match the collector impedance of Q1 to the base impedance of Q2, Q3 and provide drive. Q2 and Q3 operate in parallel as a class C amplifier which provides good efficiency.

These 2N3866 transistors, Q2 and Q3, are being pushed to their limits in the Fun-Mitter circuit. Under some load conditions, some hams have discovered that Q2 and Q3 can be destroyed. To avoid this, either reduce the supply voltage to 20 to 22 volts or increase the value of R5 and R6 to 4 to 5 Ohms. Also, the 2N3866 part can be replaced with the much more rugged 2N3553. The only other components needing change are C4, C5, and L4 which, together, comprise a pi-network filter. Component values are given in the Parts Lists.

The Fun-Amp schematic is reproduced in Fig. 2. Using the Fun-Amp on other frequencies is even easier than using the Fun-Mitter on other frequencies. Only L2, L3, and C3 need to be modified. The input circuit remains completely un-

La	26 turns removed	28 turns removed
Lb	26 turns removed	28 turns removed

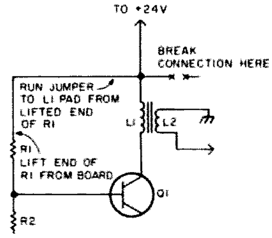

Fig. 4. Modification to allow "spotting" of transmitter (use when using PC pattern from the February, 1981, 73).

changed. This circuit operates very well at 15 and 20 meters due to the excellent frequency characteristics of Q1-Q3. A detailed circuit description is given in the Fun-Amp article.

Two additions have been made to the higher-frequency versions of the transmitter and amp. Fig. 3 shows a half-wave harmonic filter which reduces harmonic radiation. Also, a 10-μF capacitor (272-1013) has been added at the key jack (J4) to shape the keyed waveform and eliminate any key clicks.

Construction

Even though the Fun-Amp and Fun-Mitter are "goof-proof" projects, care and thought must be put into their construction. Although the fifteen- and twenty-meter versions are as simple as the earlier models, it might be helpful to review some pitfalls to watch for.

For best results, use of a PC board is strongly recommended.[5] Refer to the earlier articles for the patterns and component locators. The 2¼" by 3" format shown in Photo B is small enough to allow mounting flexibility. I would suggest that this format be followed. Combining several bands, amplifier, transmitter, etc., on one board can lead to problems, particularly if you are inexperienced in homebrew.

Before building, develop a plan as to how you will load the boards, assemble the unit, and test. After the plan is developed, proceed carefully. Most problems are due to misloaded parts, poorly soldered connections (rosin-core solder is a must!), faulty components, and hasty build-and-test. Most of these problems can be avoided by developing a plan and carefully and thoughtfully following it.

Radio Shack rf chokes are used as inductors by removing turns as necessary. Fifteen- and twenty-meter circuits require less inductance and, therefore, the coils will have fewer turns. In constructing the coils, be sure that the exact number of turns is removed and that insulation is scraped from the end of the wire that will be resoldered to the coil form. The three-turn Fun-Mitter coil (L2) that is wound over L1 should be wound in the same direction as the turns of L1. Also, wind it over the end of L1 that is mounted nearest Q1. The excess wire cut off when the turns are removed is excellent for wiring L2. Refer to Photo B for a view of the coils.

It is best to construct a single band in one box rather than combining bands. This is slightly more costly due to duplication of some parts, but it eliminates switching problems completely.

An advantageous modification to the Fun-Mitter is to allow a "spotting" function. This is helpful when finding your frequency on your receiver without transmitting on the air. This is accomplished by continuously applying 24 V to the oscillator stage. To do this, break the connection between L1 and L3, then connect L1 directly to 24 V. Also, one end of R1 is removed from the circuit board and a wire from it run to the 24-V side of L1. With this modification, pressing the key will produce a note in the receiver with the send/receive switch set to receive. See Fig. 4 for details of the modification.

Crystals can be obtained very easily. After deciding on either FT243 third overtone or HC6U fundamental, both crystals and sockets can be ordered from a supplier such as CW Crystals or Jan Crystals.[6]

Adjustment

Adjusting the high-frequency Fun-Mitter and Fun-Amp is just as easy as with the low-band versions. Again by thinking carefully through the process, the rig can be set up without problems in a short time.

If possible, find a VOM to use at this stage. Although not absolutely necessary, it is much more helpful and educational to see what is happening during tune-up. Begin by ensuring that you do indeed have a 24-V source (either lantern batteries or the Fun-Mitter power supply). Measure the voltage. With +24 V disconnected, measure the resistance at the voltage-input connector to ensure that no shorts exist to ground (use Ohms scale).

It is essential that a dummy load be connected to the antenna connector at all times during tune-up. For the Fun-Mitter/Fun-Amp combination, a dummy load capable of dissipating 20 Watts will be needed. Without a load, the transistors will be destroyed quickly.

The final step in tune-up is to attach an ammeter and begin testing! Connect an ammeter capable of measuring at least 1.5 Amps in series in the +24 line going to the gear. Set the T/R switch (S1) to "transmit." With the Fun-Amp switched

out, the meter should read around 300 mA with the key pressed. Switching the Fun-Amp in should produce a reading of around 1.2 Amps with the key down, indicating a power input of around 30 Watts.

As can be seen, there are no adjustments to be made. This is one of the beauties of the gear. After building the units carefully, they should work the first time with no adjustments!

If trouble is encountered, check the following:

1. Isolate the problem to a stage—Fun-Mitter, Fun-Amp; if Fun-Mitter, does oscillator work?
2. Measure voltages at collectors and drains of transistors with T/R switch in T position (should read 24 V).
3. Check for wiring errors.
4. Check soldering.

Operating

The thrill of home-brew construction comes in the actual operation. Making contacts with gear you built yourself is fun! The high-frequency Fun-Mitter and Fun-Amp easily will produce worldwide contacts. Twenty Watts on 15 or 20 meters can bring in contacts from all continents easily.

With the capability of 15- through 80-meter operation with the Fun gear, WAS, WAC, and DXCC are all within reach. Good luck! ■

TUSA

A WHOLE NEW WORLD OF TV VIEWING WITH TUSA'S NEW MODEL CVU-40, 40 CHANNEL CABLE TV CONVERTER

Receive all the EXTRA CABLE TV "MIDBAND" & SUPERBAND CHANNELS on your UHF DIAL.

Eliminates the need for renting or leasing. This stable and reliable system converts extra cable TV channels so they can be received on the UHF tuner of your TV set.

Use of this unit may be subject to rules by your local cable TV Co.

A MUST FOR VIDEO-TAPING FROM CABLE TV!

The system allows you to program both pay (pay TV decoder required) and standard cable channels for taping on any VCR — while you are watching a different channel on your TV.

Simple to install and operate on any make of TV with UHF.

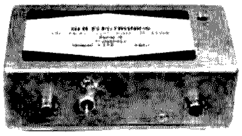
HIGH PERFORMANCE PRESELECTOR-PREAMP

The solution to most interference, intermod, and desense problems in AMATEUR and COMMERCIAL systems.



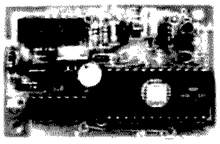
- 40 to 1000 Mhz - tuned to your frequency
- 5 large helical resonators
- Low noise - High overload resistance
- 8 dB gain - ultimate rejection > 80 dB
- 10 to 15 volts DC operation
- Size - 1.6 x 2.6 x 4.75" exc. connectors
- FANTASTIC REJECTION!

Typical rejection:
±600 Khz@144 Mhz: −28dB
±1.6 Mhz@220 Mhz: −40dB
±5 Khz@450 Mhz: −50dB

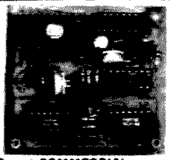
Price - $69.95 bipolar w/RCA jacks
Connector options: BNC $5, UHF $6, N $10
SUPER HOT! GaAs Fet option $20

AUTOMATIC IDENTIFIERS

ID-1



ID-2



- For transceivers and repeaters - AMATEUR and COMMERCIAL
- Automatic operation - adjustable speed and amplitude
- Small size - easy installation - 7 to 15 volts DC
- 8 selectable, reprogrammable messages - each up to 2 min. long
- Wired, tested, and programmed with your message(s)

Model ID-1 - $39.95 Model ID-2 w/2 to 10 minute timer - $59.95

We offer a complete line of transmitter and receiver strips and synthesizers for amateur and commercial use.

The Ultimate Breadboard

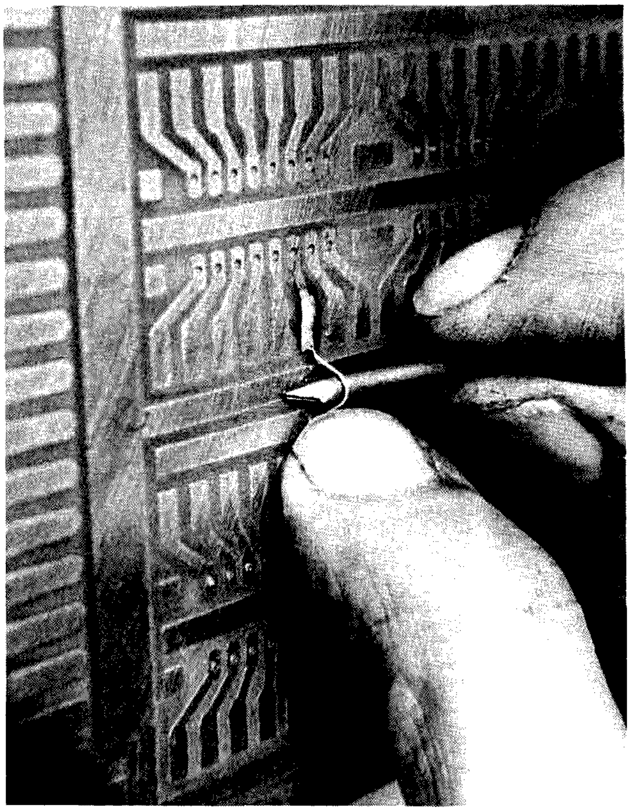
There used to be two styles of prototypes—rat's nest and cramped. Now there is a third style—simple.

There are at least a dozen different boards on the market intended for prototyping and one-of-a-kind construction projects. Most that I have used in my ham activities, in the classes at Los Angeles Access, and professionally have either been lacking in flexibility and ease of construction or are difficult to circuit trace.

Of the commonly-available types, the wire-wrap board, for example, is extremely difficult to circuit trace, especially when the component density reaches a certain point. This is complicated by the fact that components must be placed in IC header plugs.

The widely-used perfboard-type with general-purpose foil pads is much too cramped, lacks definite locations for ICs, is too difficult to circuit trace, and is prone to solder bridges.

The third common type, consisting of many small squares, works reasonably well for small projects. However, it becomes entirely too large for bigger circuits. It also lacks definite locations for components, especially ICs.



Forming a short jumper from bare wire using a small round tool and the end of your finger.

The board shown here solves many of the problems by combining a number of the good features of all systems into one, all contained on a standard 4½"×6½" 22-pin edge-connect card. The connector may be cut off easily if it is not used.

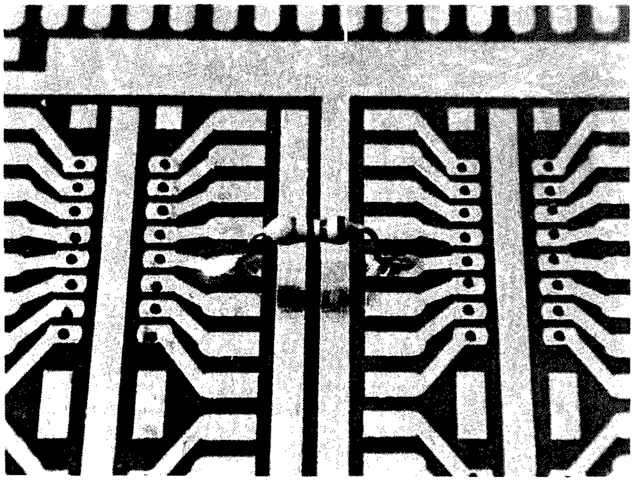
The basic features of the board are sixteen 16-pin DIP patterns for small ICs and one 40-pin pattern for larger ICs such as microprocessors, UARTs, etc. Alternately, the larger pattern will accommodate two additional 16-pin ICs.

Two continuous power rails run throughout the board and are available on both sides of all IC patterns. There is also a set of pads and a foil area for a 3-terminal tab-type regulator. On the opposite end from the edge connector are a number of small pads for switches or indicator LEDs.

Locating Components

Components may be mounted on either side of the board. In some cases, #60 holes will have to be drilled in the plain pads for this. For experimenting, however, all components including the ICs are best placed on the foil side. This leaves the entire circuit in view without turning the board over. In this way, the circuit is much easier to visualize.

For more permanent projects, some of the larger components and the ICs are best placed on the non-foil side. Buses of many wires are also better on the back to keep them out of the way during testing and repair. Resistors, small capacitors, and most interconnecting wires should be on the foil side.



A component properly formed and soldered to the board.

Attaching Components

The biggest mistake most first-time users of the board make is looping components too high. Keep everything as tight against the board as possible. All components should be preformed, with leads kept as short as possible. After soldering, give the component or wire a gentle bend back and forth to relieve lead stress. This is important, especially when connecting another component to the same spot, as it will prevent the first component from moving when the solder is remelted.

Do not connect components in midair. Even if you have to tie one end of a component to an unused pad and complete the connection with a piece of wire, the final result will be much neater and less likely to be damaged by subsequent handling. By the same token, it is wise to use the same technique to avoid crossing components over ICs. If you have to replace the IC at a later date, it will be much easier if you do not have to remove other components.

For long interconnections, use insulated wire. For close or adjacent pads, bare tinned wire is best. To jump over a pad or rail, form the bare wire as you install it. Using a long piece, solder one end first. After the solder hardens, bend the long end up at about a 45° angle. Next place a small round tool, like a common nail, on the pad to be jumpered. It will be easy, then, to bend the wire down over the nail into contact with the pad to which it is to be soldered. Clip the end with small diagonal cutters and then solder.

I recommend wire-wrap wire for use on the board. It is available in inexpensive small rolls at most electronic parts stores. It has solid conductor and heat-proof insulation. Stranded wire or wire with ordinary PVC plastic insulation is very hard to work with. You also may need to buy a little stripping tool—ordinary strippers often work poorly on wire-wrap wire.

Plan Your Work

It is quite a temptation, because of the ease of construction using the board, to simply grab components, wire, and solder and to begin building without planning. Even if you are doing original design work, give the layout of the board some preliminary thought. I find it invaluable to literally draw out the project in pencil. The main benefit is in reducing the number of "across-the-board" wires. It's not possible to eliminate them all, but a little planning reduces the number and makes the final board much neater and easier to repair in the future.

Conclusion

For original design work, for student use, and for producing permanent repeater control systems, the board has become very popular in my local group. Personally, I like it best for "one-of-a-kind" projects that appear in ham magazines. Many articles do not contain board layouts. The board has provided a very satisfactory and quick means to build such projects. It also greatly facilitates modification of published circuits to one's own needs in a form that is genuinely permanent.

The prototype board is available commercially from W6ELECTRONICS, PO Box 5515, Pasadena CA 91107, for $6.95 (California residents add 6% sales tax). For home construction, a photographic negative is available for $4.95. The board is made of G-10 glass epoxy, drilled, and rosin-coated. ■

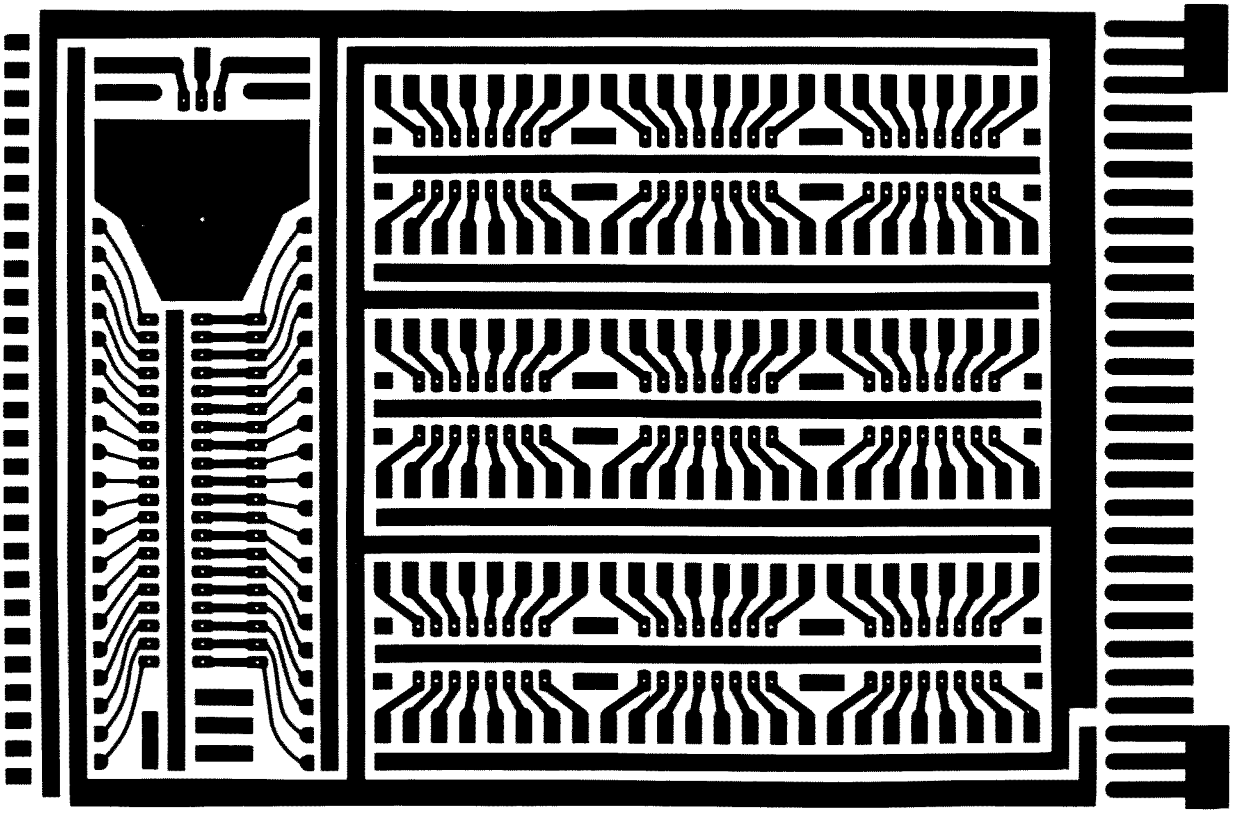


Fig. 1. The better prototyping board.

Beating the Untraceable Buzz

Man-made interference doesn't have to destroy reception. Not when you use W1GV's buzz-beating antennas.

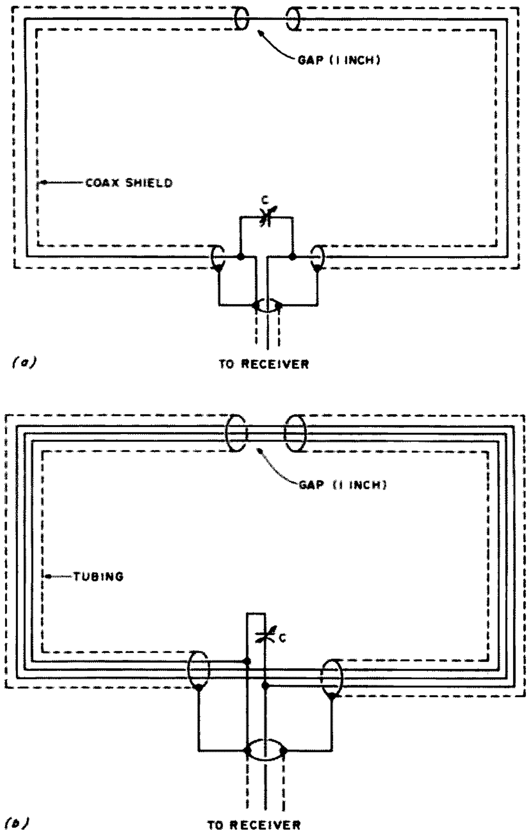

Fig. 1. Two versions of the shielded loop. (a) A single-turn version may be constructed using tubing and heavy wire or by using coaxial cable. The value of C will have to be determined by experimentation, although a 365-pF receiving-type variable usually will suffice. (b) A multi-turn loop is shown. Circumference of the loop should be about 0.15 wavelength in either case, although it may be considerably less if a preamplifier is used. See text.

Stan Gibilisco W1GV/4
PO Box 561652
Miami FL 33156

You've just moved into a new apartment or a new house for rent and the landlord has given his okay to your putting up a four-band trap vertical on the roof. (Miracles do happen!) So you blithely install your new station console, trying to improve the layout still further over what you had the last time; you painstakingly solder every PL-259 onto the interconnecting cables. You ground your equipment with a bus bar of 1/4-inch copper tubing running to a cold-water pipe only three feet away. You install 20 radials on the roof for each band (80 in all, and with the best stranded No. 16 wire). Finally, everything is ready to go.

Frequency MHz	Circumference Feet	Meters
1.8	78	(24)
3.5	40	(12)
7	20	(6.1)
10	14	(4.3)
14	10	(3.1)
18	8	(2.4)
21	7	(2.0)
24	6	(1.8)
28	5	(1.5)

Table 1. Circumference of a shielded loop for various frequencies. These circumferences represent 0.15 wavelength for the indicated bands. If a preamplifier is used, the loop may be used at frequencies below that where it is 0.15 wavelength.

You turn on the receiver. A solid installation, this, you proudly think to yourself. Not a DX killer, to be sure, but it's well built and there should be plenty of good hamming ahead. The S-meter reads a steady S9 + 20. You turn up the volume: ZZZZZZ! Up and down the band you tune. The noise limiter does no good; the pulses must be too broad. ZZZZZZ! So much for 20 meters.

Switch to 40. Peak up the preselector. ZZZZZZ! S9 + 30. Damn. Switch to 15. Peak it up. ZZZZZZ! Only S9. Oh, great! Why even try 10? Why make yourself depressed needlessly?

The Search Begins

The next step, of course, is to switch off everything

in the place except the rig. Thwack! Thwack! Thwack! One circuit breaker after another. And from the shack, several rooms away, you can hear the receiver with the volume up to 3:00: ZZZZZZZ—it stops! Your heart leaps. Whoops, that was the shack. Thwack! ZZZZZZZ...

The XYL shouts, "Will you turn that thing down and stop fussing with the lights? I'm trying to watch TV and iron!"

All your clocks were set to WWV from your watch, which you had to set at a friend's QTH because you can't even hear WWV at yours. Now all the clocks are out of whack since you played with the breakers.

You run all over the yard, using a little, plastic 6-transistor AM radio your Aunt Jenny gave you for Christmas back in '65 and you've hardly used for anything until now. Some places the noise is louder, some places softer. But there is no logical pattern. It's everywhere, but it's centered nowhere.

You try to DF (direction find) using the ferrite loopstick in the little radio. There is a sharp null in the direction of either the elm tree out front, or else 180 degrees opposite, from somewhere under the driveway. Move into the backyard. It's either coming from the rising full moon or else from the base of the swing set.

No power transformers of any consequence in the area. The noise is constant, around the clock. You get up at 5:00 am: ZZZZZZ! You come home for lunch (actually, instead of lunch). ZZZZZZ! Your stomach growls.

You'll never get rid of it.

You Could Search More

Oh, yes, eventually, if you search long and hard enough, you'll find it. Maybe it's an electric blanket in a neighbor's house. But, then, who uses an electric blanket for 24 hours out of every day? A refrigerator? Maybe, but they don't run continuously, unless... unless there is not enough of that coolant stuff in them. Hmmm.

It's not a street lamp starter, since it happens during the day. A fluorescent lamp starter, maybe? Well, who leaves a fluorescent lamp on for 24 hours a day? You might snoop around the neighborhood at 4:00 am or so and see if anybody has any fluorescents on. But, no, you might get arrested or mugged or something.

Maybe it's a thermostat mechanism. God help you.

What Can You Do?

Although I've made light of all this, it's not exactly funny when it happens. And sometimes you just will not, by any reasonable means, be able to locate and/or eliminate a source of man-made noise. If it's somebody's refrigerator without coolant, maybe it will burn up some day. A noisy fluorescent light starter will eventually fail and have to be replaced. Lot of good that does you now.

The situation is not hopeless, though. Noise has different characteristics than signals. There are ways of getting your antenna system to favor those single-frequency signals that you *want* to hear, while discouraging that wide-band hash that you *can't stand* to hear.

There are basically three methods of doing this. You can use them in combination if necessary. They will almost always provide significant improvement. These methods are: 1) Shielded-loop antennas; 2) High-Q antennas; 3) Noise-cancelling antennas. Let's look at these one by one.

Incidentally, these antennas are for receiving only. If you have a transceiver, some sort of switching device, such as a relay, will have to be used. These antennas will all prove quite lousy for transmitting.

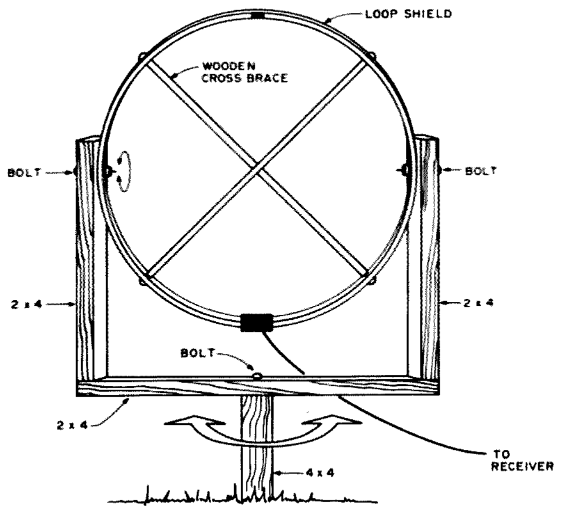

Fig. 2. A method of azimuth/elevation mounting that allows the shielded loop to be pointed towards the focal direction of a noise source. This kind of mount is practical only up to a certain size—about an 8-foot-diameter loop. The loop shield should be constructed from copper tubing if this kind of mounting is used.

The Shielded Loop

Fig. 1 shows two types of shielded-loop antennas. Fig. 1(a) is a schematic diagram of a single-turn loop, which may be constructed from coaxial cable. The loop is tuned to resonance by capacitor C, which may be a common 365-pF receiving-type variable available at most Radio Shack stores. It may be necessary to parallel this capacitor with a 330-pF fixed capacitor if resonance cannot be obtained with the variable by itself.

The loop should have an overall circumference of about 0.15 wavelength. Essentially, it is a single-band affair. If used on a band much lower than where it is 0.15 wavelength, the antenna will not pick up signals very well. If used on a much higher frequency, the antenna will pick up more noise. Nevertheless, you can probably get away with using it at half the design frequency and still get fair results. The loop may be placed on an "X" brace made out of wooden dowels or 2 by 4s, taped to an inside closet wall, or even put up in a tree.

The "shielding" of the loop obviously is not complete. Actually, it is electrostatic (Faraday) shielding, which shorts out the electric component of the signal while letting the magnetic part pass. For some reason, man-made noise seems to be transmitted mostly by capacitive coupling, as an electric field. But signals have both a magnetic and electric component. The result is that the noise gets attenuated more than the signals.

At Fig. 1(b), we have a multi-turn shielded antenna. The overall physical circumference should still be 0.15 wavelength. The shield may be constructed out of copper or aluminum tubing. The loop should have four to six turns; too many turns will lower the Q of the antenna and this will adversely affect its noise per-

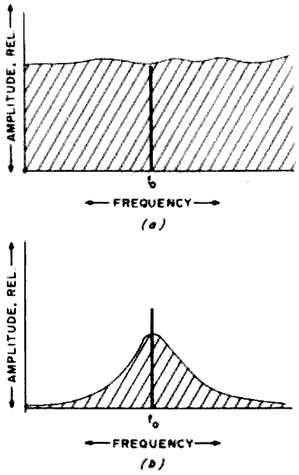

Fig. 3. Effect of increasing the Q of an antenna system. (a) The antenna system has essentially no selectivity. The signal, at frequency f_0, is buried in the noise. (b) A selective circuit is used in the antenna system. The total amount of noise (area under the curve) is smaller and this results in fewer high-order mixing products, which actually reduces the noise level at f_0. But the signal level remains unchanged, improving the signal-to-noise ratio.

formance. (Part of the noise attenuation of the shielded loop is the result of its high Q, which we will discuss later.) Several turns, however, provide for more "sensitivity" than just one. One word of warning: It is a physical contortion of considerable difficulty to find a way to get several turns through the tubing without a good deal of cussing and high blood pressure.

Table 1 gives the circumference of an 0.15-wavelength loop at various frequencies. The loop may be a square, pentagon, hexagon, octagon, or perfect circle. The circle is geometrically best. A long, skinny rectangle will not work too well. You should try to get the largest possible area for the circumference allowed, and keep it all in the same plane.

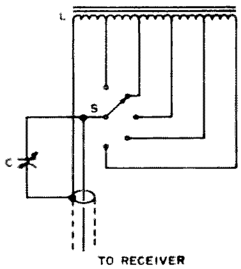

Fig. 4. A ferrite loopstick antenna with multiple taps. The taps should be chosen so that C may be adjusted for resonance on each band used. See text for discussion of inductance values.

A shielded loop does have a directional pattern. The antenna will respond to signals in any direction except right along the axis. There is a sharp null in the line of the axis. The null is so sharp that signals propagated via the sky wave will never fall into it because of their multipath nature. Local signals might possibly fall into the null; just move the antenna a little and they'll come up. Of course, the noise can be nulled out if the antenna is oriented just right. This will provide even more attenuation to an already weakened foe.

Nulling It Out

The noise that is causing you so much frustration may originate in a single device, but it is probably being transmitted all over the place by the ac power lines. Therefore, it may be coming from all around. However, noise will always have a *focal direction*. Mathematically, all the noise combines in such a way that it may be considered to be coming from one single direction. (It's sort of like gravity. Even parts of the Earth that aren't straight under you are pulling at you, but it all averages out to a straight down force.) This axiom holds true as long as it's only one fluorescent light, thermostat, or elm tree that is responsible. If there are two independent culprits, each one will have its own focal direction, and you won't be able to null them both out at once. But chances are that there is only one source of noise. (It is just too horrible to even consider that there might be more!)

Fig. 2 shows a method of mounting a shielded loop so that its null can be pointed in any direction. The focal direction might even be straight overhead, so the antenna must be capable of pointing in the vertical as well as the horizontal plane. The XYL won't let you put such a contraption in the living room? Well, try the attic or the backyard, then. Or even the roof.

It may take some time to find the focal direction of the noise, since the antenna null is so sharp. But once you've found it, there may be as much as a 20-dB drop in the noise level—and this is in addition to the improvement that results from the electrostatic shielding. Now you should be able to hear some signals. Let that guy's refrigerator run until it burns itself out.

High-Q Antennas: The Ferrite Loopstick

Man-made noise differs in another way from signals. The signal you want to hear is never more than 3 kHz wide on the HF bands (unless you want to listen to AM shortwave music broadcasts, which take up about 10 kHz). The noise, however, is hundreds or even thousands of kHz wide.

The higher the Q (the narrower the bandwidth) of the antenna system, the smaller the total amount of noise that gets into the receiver. But that little 3-kHz signal will all be passed. This effect is shown in Fig. 3. The less total noise that gets to the receiver front end, the less noise that will appear within that 3-kHz signal "window," since there will be a lower level of high-order mixing products. Thus, the signal-to-noise ratio will be better.

The shielded-loop antenna, discussed earlier, has a fairly high Q. It can be maximized by using a single turn of very heavy wire inside a piece of tubing, or else by using RG-8/U coaxial cable for the loop section. A preamplifier with rf tuning may be added at the receiver input with any antenna in order to increase the Q. There are several commercially made units available. Ameco Equipment Company (12033 Otsego Street, North Hollywood CA 91607) makes one called the PT-2 that tunes 160 through 6 meters.

An antenna with very high Q can be constructed using a ferrite rod. Just wind several turns of enameled copper wire on the ferrite core from the antenna in Aunt Jenny's at-last-useful AM transistor job. Ferrite sticks are available commercially from Amidon Associates (275 Hillside Avenue, Williston Park NY 11596). The coil should be tuned to resonance using a variable capacitor. Fig. 4 shows a multiband ferrite antenna system with multiple taps.

The exact number of turns that will provide resonance on the desired band using a 365-pF variable capacitor at C will have to be found by trial and error, unless there is data included showing inductance vs. number of turns for your particular stick. Table 2 shows the values of inductance that will provide resonance with 200 pF of capacitance (about the middle of the range of a 365-pF variable) at various frequencies.

A ferrite antenna, complete with azimuth/elevation mount and a built-in

Table 2. Inductance required to resonate with 200 pF of capacitance (the middle range of a 365-pF variable) at various frequencies. This data may be used in conjunction with data provided with commercially available ferrite rods, for the purpose of making a ferrite loopstick antenna.

preamplifier, is available from Palomar Engineers (Box 455, Escondido CA 92025) at the time of writing.

The ferrite loopstick is not electrostatically shielded, but it does tend to favor inductive coupling over capacitive. It is easier to work with mechanically, especially at lower frequencies. Simply orient the loopstick until a null occurs in the noise background. The null will be very sharp.

Need this last comment be made? Let's not take any chances. Don't try using a toroid core for this antenna. It won't work.

Noise-Cancelling Antennas

There's still another characteristic of noise that makes it different from signals. Oddly enough, this is the very resemblance of noise to a signal, with a unique focal direction. You hear the noise on the same frequency as a given signal; the noise may be thought of as a local signal. As such, using two antennas to combine the noise in opposite phase, the noise can be "cancelled out."

Fig. 5 illustrates one such system. The spacing between the two inductively-loaded vertical dipoles need not be very great, but it should be as large as practical without exceeding a quarter wavelength. The elements themselves may be very short. In fact, shortening them increases the Q, which will add to the noise-reducing effectiveness.

One antenna is fed 180 degrees out of phase with respect to the other. The easiest way to do this is to make the phasing lines the same length, but feed one of the antennas upside down with respect to the other. That is, if one antenna has the feedline center conductor going to the top section, the other antenna should have its feedline going to the bottom. In the plane equidistant from the two antennas, phase cancellation will occur. This is a vertically-oriented plane, and by rotating the entire system through 180 degrees, any focal direction can be put into the null plane.

It is possible, but not likely, that a signal will arrive from a direction that lies in the same plane as the noise, once the noise has been cancelled out. Sky-wave signals, since they arrive from a varying direction (ionospheric shift), may fade more if this happens. Local signals will be attenuated considerably.

This particular kind of antenna is mentioned here to illustrate the third way that signals can be distinguished from noise. As described, it will not work as well as the shielded loop or the ferrite antenna. But this scheme could conceivably be used with *two* shielded loops or ferrite antennas! Actually, pointing these two types of antennas at the focal direction of the noise is a means of phase cancellation. But even more cancellation could be obtained by using two such antennas, both pointed at the focal direction of the noise and then combined so that the small amount of remaining noise from each antenna arrives at the receiver in opposing phase.

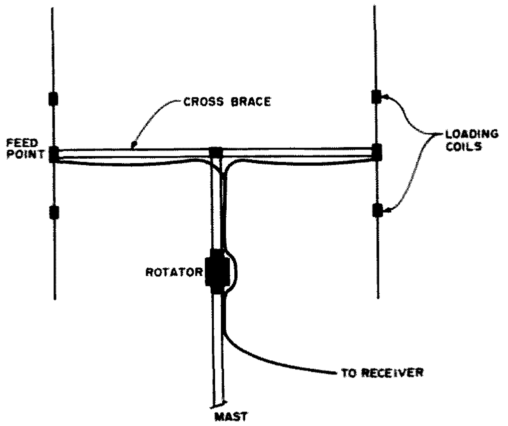

Fig. 5. Using two antennas to obtain phase cancellation of the noise. This particular system uses two inductively-loaded vertical dipoles. This system is illustrated primarily to demonstrate the third difference between signals and noise; this antenna by itself will not work as well as a shielded loop or a ferrite antenna.

Which One?

In a noisy environment, probably the best choice is the shielded loop. Using a selective preamplifier, one shielded loop can be used on several bands; it should be constructed for the highest band used. On lower frequencies, the value of capacitor C will have to be increased by paralleling it with fixed capacitors. The preamplifier will allow reception on lower bands because of its gain.

Perhaps there is no good place to put a shielded loop with azimuth/elevation mounting, and you can't get enough noise attenuation unless the antenna can be oriented towards the focal direction of the noise. Then, the next best choice is the ferrite loopstick. It can be put right at the operating desk! The ferrite antenna will probably not be quite as effective as a shielded loop. The null will not be as well defined (though still quite sharp) and its discrimination against electrostatic coupling will not be quite as good. But it can still be used to advantage.

Conclusion

Noise differs from signals in three ways: 1) Noise is transferred mostly by electrostatic coupling, but signals are transferred by electromagnetic fields; 2) Noise is broadbanded, but signals occupy only a small part of the spectrum; 3) Noise has a unique and usually constant focal direction at a given frequency, and it will usually be in a different focal direction than desired signals. These three differences are taken advantage of by: 1) Faraday shielding; 2) High-Q antenna circuits; 3) Phase cancellation.

These three methods of dealing with noise may be used individually or in combination. A shielded loop with azimuth/elevation mounting takes advantage of all three of the differences between signals and noise. It has electrostatic shielding, has a high Q, and may be oriented to null out the noise. A ferrite loop can be used when the shielded loop is impractical because of space limitations, either in reality or in the imagination of an XYL or landlord.

Good luck! Carry on the search for the noise source by all means. But at least get on the air in the meantime.■

The Care and Feeding of Optoelectronics

There are many ways to make these devices earn their keep. Here is one.

Can you really see which way the wind is blowing with optoelectronics?

The answer to that question is yes—with a little help from you.

The subject of this article is General Electric's H21A1 photo-coupler interrupter module. This module has two components: an infrared LED light source called the emitter, and a photo transistor called the detector.

I think you are safe in believing this so far, because I just read it in an optoelectronics manual.

The H21A1 module has a gap in its housing. The emitter is mounted on one side of the gap and the detector on the other. You may think someone planned it that way because now, if you want to, you can make this little black thing do something to earn its keep. For instance, if you pass something opaque through the gap, you will interrupt the output of the emitter. Do you think that's why GE calls it a photo-coupler interrupter module?

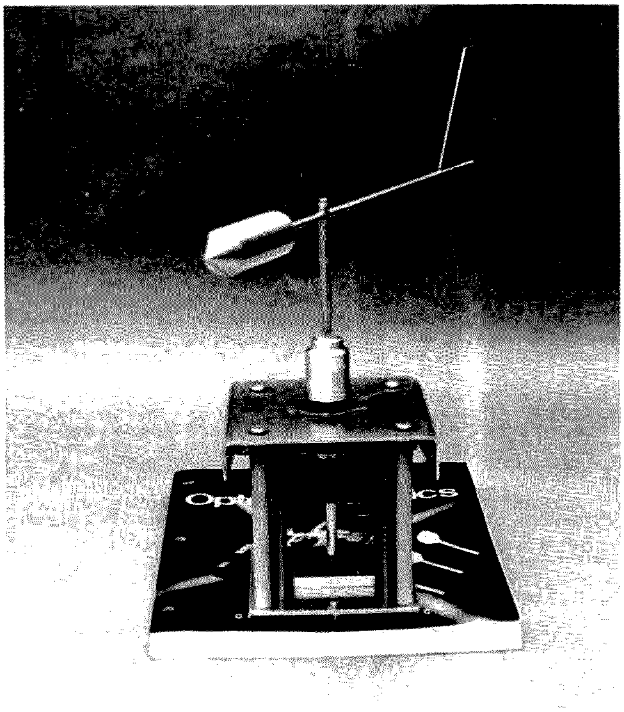

Photo A. Wind-direction indicator with the weather cover removed.

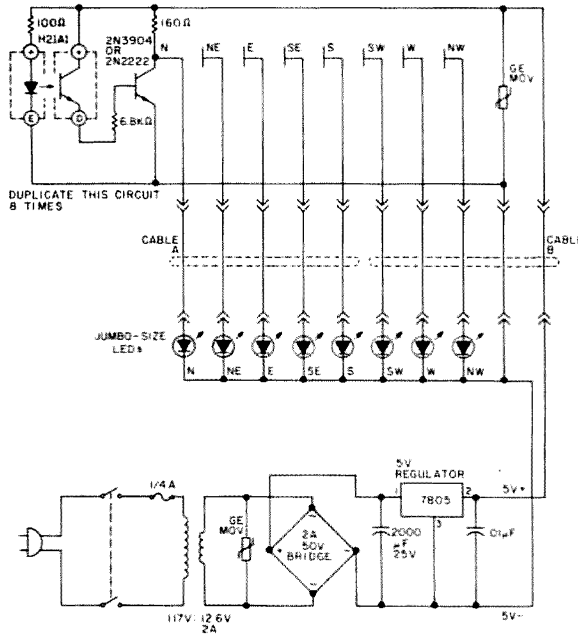

Fig. 1. The H21A1, detector side, is not shown physically correctly drawn here—look on top of the device for the correct pinout. All resistors are 1/4 Watt; capacitors are μF.

The interrupter module is just one of many types of photo couplers. To mention a few, the reflector module could be used somewhat like the interrupter module except that the light source must be bounced off a reflective surface and back to the detector. There are discrete emitter and detector units, and also a whole family of optocouplers in which the emitter and detector are sealed into one cube with no way of anything getting between them, which offer as high as 4000-volts isolation between the input and the output. I have mentioned but a few that are available (most of them cheap). And that brings me to the reason for my taking your time while you read this.

My purpose is to tell you how I used an interrupter-type module in a project and to get you interested enough to think about using optoelectronics in *your* next project. The more you know about them the more jobs you will see that they can do for you.

I sort of hinted at the beginning that I know how to make the H21A1 (actually, 8 of them) tell which way the wind is blowing, so I better get to it. The construction part is a mix of electronics and mechanics. The device, in case you haven't guessed, is a wind-direction indicator.

As you can see in the photos, there are some machined parts used on the model. Don't let this scare you; in almost every case, there is an alternative way to fabricate the same part with hand tools. I will suggest ways as we go along. On the other hand, the fellow with a lathe or machine shop could have a good time developing this project even further. The model pictured here has been perfected only to the point that it works reliably in all weather experienced here in Pennsylvania, and it should continue to work for many years. That is to say, don't be afraid to use the ideas and hardware available to you.

The most important points to remember when planning your construction are that (1) the bearing friction should be low enough so that a gentle breeze will have enough force on the tail of the vane to keep it headed into the wind, (2) you must devise a way of mounting it to your tower or pole, and (3) when it's all finished you must have some means of weather-sealing it.

Photo A shows the wind-direction indicator fully assembled except for the weather cover. The vane boom is 3/16 × 12-inches-long aircraft aluminum rod. (I might mention at this time that all parts were made from T3 aluminum.) The tail is 1/16 × 6 inches and has just about 13 square inches of surface. The vane boom is mounted to the axle or vertical shaft 2/3 of the length of the boom in front of the tail, or 1/3 of the way back of the nose. So, to balance this boom, the nose must be proportionately heavier than the tail. The nose is 1 × 3 inches long and is threaded onto the boom. A 1/16-inch slit has been milled into the boom to accept the tail, but a flat surface filed on the boom with the tail screwed to it would be just as good. The nose could be epoxied to the boom if there is no threading tool available.

The axle or vertical shaft is a 1/4 × 9-inch rod with a a 3/16-inch hole drilled in it near the top to accept the vane boom. A hole was drilled and tapped into the end of the shaft down through the vane boom and on into the shaft another half inch to secure the boom to the shaft.

Photo B is an exploded view. It shows the next component on the way down the shaft—the top bearing weather seal. This rotates with the shaft and, together with a piece of pipe that is epoxied to the top support frame, prevents the elements from getting into the bearing.

The top support frame is 4-7/16 inches deep (as viewed in Photo B) and 4-5/8 inches wide. It provides a mounting surface in the back and was formed from 1/8-inch stock. The back two corners were welded for strength. The inner bear-

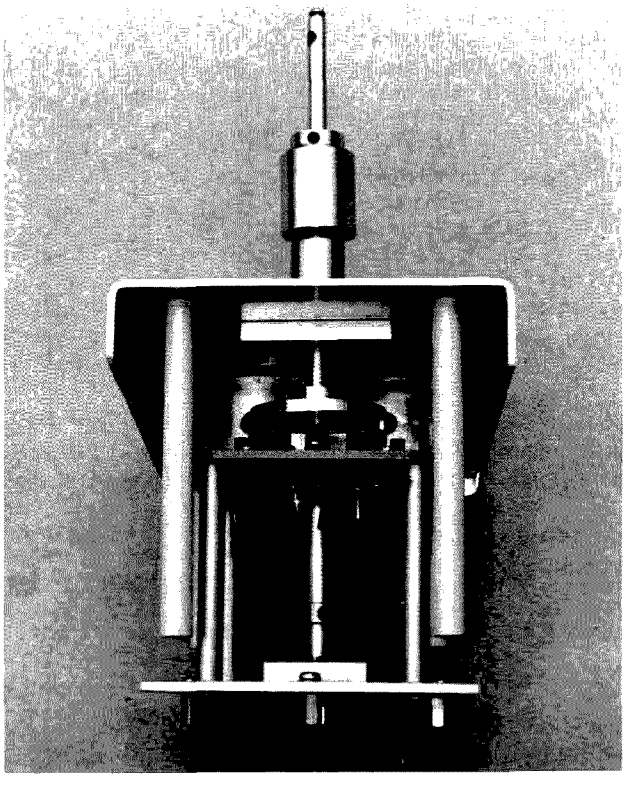

Photo B. An exploded view with the vane boom removed.

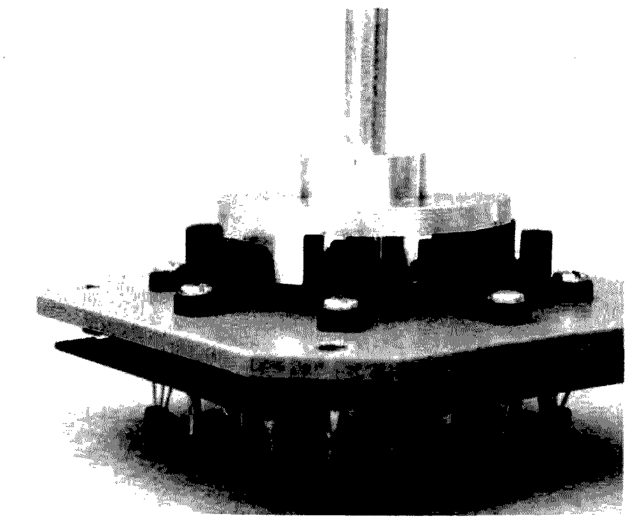

Photo C. A view of the H21A1s mounted on their fiberglass substrate and the disc interrupter tab rotating through the H21A1 gap. Mounted underneath is the PC board with the rest of the circuit components.

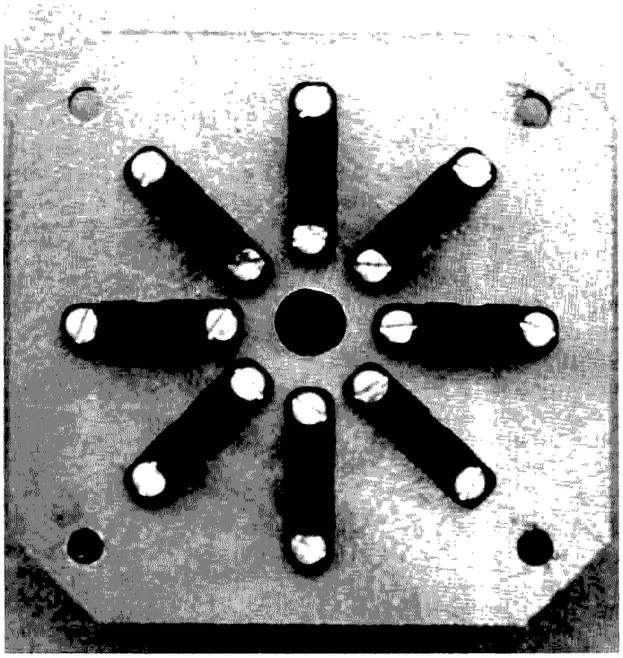

Photo D. The eight H21A1s in a 1-11/16" circle (measured to the center of the gap).

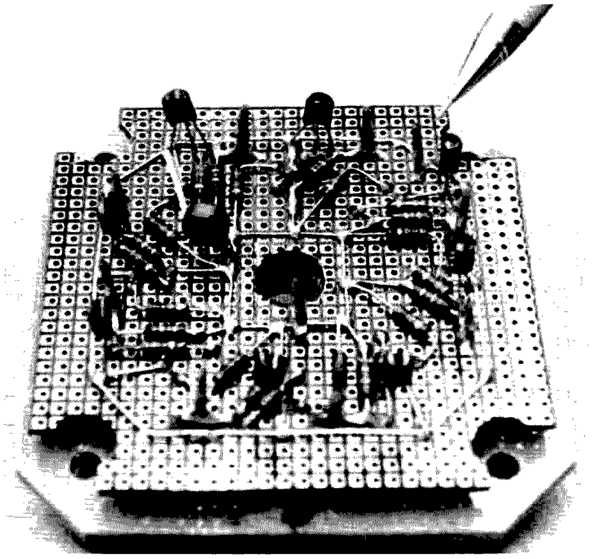

Photo E. The electronic components mounted on what we call a "do all" PC board. The pencil is pointed at one of the ten pins used to terminate the cable coming from the readout LEDs in the shack. The component at 10:00 o'clock near the shaft hole that looks like an overweight disc capacitor is the MOV.

ing seal is 3/4-inch i.d. conduit 1-1/8 inches high. The outer bearing seal is 5/8-inches i.d. × 1-3/8 inches high.

The next component down the shaft is the top bearing. I used ball bearings pressed into a bearing block to facilitate mounting and alignment, but a neat hole in a hunk of brass would be just as good. It would then be smart to use a brass or steel shaft, because brass and aluminum don't get along, especially out in the weather.

The next component down the shaft is the disc interrupter. It rotates with the shaft and is the component that actually tells the optoelectronics interrupter module which way the wind is blowing. (More about that later.) The disc interrupter used in this model was machined from a piece of solid round stock. As seen in Photo C, it is merely a disc with a collar and set screw to secure it to the shaft, and with a right angle tab on it. An easier way to make the disc would be to use the top portion of a small soup can and epoxy a collar to the top to secure it to the shaft. My disc-interrupter tab runs in a 1-11/16-inch circle and is 3/8-inch deep. The width of the tab is cut so that it covers two interrupter modules. (More about that later.) The H21A1's gap is 3/32-inch wide so I made the tab 1/16-inch thick.

Photo D is a top view of the heart of the whole thing, the eight H21A1 interrupter modules mounted in their circle on a piece of fiberglass epoxy board 1/8-inch thick × 3-1/4 inches square. This would have been a perfect situation in which to design and etch a printed circuit board. At the time, however, I did not have on hand PC board material thick enough to do the job. I think it should be at least 1/8-inch-thick stock to get the thermal and mechanical stability needed.

As you can see in Photo E, I used a piece of Radio Shack "do all" board. The leads from the H21A1s were stuck through the board and soldered first, to set the spacing between the two boards. Then the positive bus (near the center of the board) and the negative bus (around the outside of the board) were put down. After that, it's just as the schematic shows. The pencil in Photo E is pointing to the terminal pin on the negative bus. There are 10 pins on the board; two are for power (+5 V and −5 V), and the other eight are the direction signals that are being sent down to the wind direction LED readout in the shack. The male pins on the board will mate with female pins on the end of the cable going to the shack.

I tried various methods of reducing the number of conductors needed in the interconnection cable, BCD, etc., but when the smoke cleared (get it?), two runs of inexpensive 5-conductor TV-antenna rotor wire were found to work fine.

The eight H21A1s are spaced every 45° around the circle. Consequently, with the eight LEDs placed on the compass rose in the shack, you are able to determine if the wind is out of the north, northeast, east, southeast, south, southwest, west, or northwest merely by observing the LEDs. However, by making the disc interrupter tab wide enough to cover two adjacent interrupter modules, two LEDs are lit. So, for example, if the south and the southeast LEDs are lit, we can assume that the wind is out of the south-southeast, or approximately 157°. Obviously, more H21A1s could be added to increase the resolution. At this point, some method of reducing the number of cable conductors between the aerial unit and the readout panel would be necessary.

The electronic theory is super simple. When the disc interrupter tab interrupts the emitter light source, the photo transistor turns off, turning the 2N3904 off, hence allowing the appropriate LED to light.

Any 5-volt power supply that can deliver at least 500 mA continuously will work. The General Electric MOV is for transient voltage-spike protection. I used the

V47ZA7 because I had them; a better choice could be made.

So far, there has been no need for rf suppression, but that is not to say you may not need to add a bypass capacitor or two.

The next to last thing on the shaft is the 1/4-inch collar. It is secured to the shaft with a set screw and rests on top of the lower bearing. It prevents the shaft from falling through. As you can see in Photo B, the collar is not in place because this is an exploded view.

Photo F shows an exploded view with the 3-3/4-inch spacer screws removed from the bottom plate. You also can see the four small 3/4-inch spacers on the bottom of the bottom bearing plate. These spacers will be used to secure the weather cover.

All of the spacers could be substituted for with all-thread rod, and then you would use the nuts to adjust your spacing. The bottom bearing and bearing block are identical to the top bearing and bearing block.

The weather cover is nothing more than a five-sided box that slides up over the lower bearing plate and butts against a cork gasket glued to the bottom side of the top support frame (gasket or cover not pictured). A fruit or soup can of the proper size also would work for a weather cover.

After the machine was fully assembled and tested, I disassembled it so that I could wash all the metal parts with dishwashing detergent. Then everything was sprayed with clear Krylon™, including the electronics board but excluding the H21A1 board.

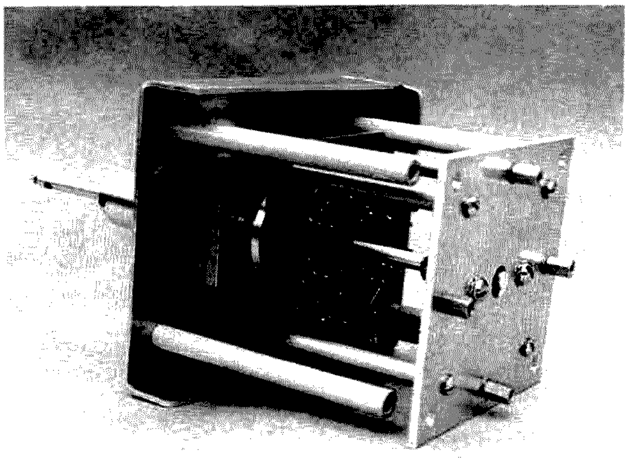

Photo F. An exploded view from the front looking up at the wind-direction indicator.

Photo G is a view of the wind-direction readout panel with its eight LEDs, etc. On a sub-panel on the rear, the power-supply components and cable terminal blocks are located. On the right is the companion meter that I hope in the near future will indicate wind velocity (not ac Amps). My plans for this meter as they stand now are to perfect a 4-inch cup anemometer to the point that it will indicate wind velocity with the additional feature of generating 7 to 10 Watts to be used to light a small lamp or to charge the HT battery.

Tune-up of this little gem is pot pie. Just mount it in the air on whatever structure you plan to use. Point the nose of the wind vane north and by using the set screw in the disc interrupter collar, clamp the tab so it is centered through the H21A1 that you have designated north. Be sure the vane still rotates freely. Secure the weather cover in place, then go down to the shack, turn the power supply on, and watch the LEDs blink. It is that simple. Of course, you knew it was going to work before you put it in the air. Hi, hi!

A word about finding parts and materials. If you can't get the H21A1s locally, see Reference 1. I found a shop in my area where I can buy a foot of this and an inch of that, plus getting some good advice to boot. I found this shop by talking to a fellow who is building an experimental aircraft. They use the same types of material. Perhaps you can find an experimental aircraft club in your area, or you can get your material where I got mine. See Reference 2.

I would be very remiss if I did not implicate my collaborators in this project: Fred Jones K3CVM,

International Success Story: The BBC

From its battery of transmitters, the BBC fires a daily salvo of news and entertainment around the world. No commercials, either.

Roger N. Peterson
25 Orchard Lane
New Canaan CT 06840

Ask just about any shortwave radio listener or look at the most recent listener-preference studies on international broadcasters, and you'll get the same answer. The British Broadcasting Corporation (BBC) ranks number one.

Bush House, home of the BBC's External Services, in The Strand, London. (All photos BBC copyright.)

There are a number of reasons for this popularity ranking, and I was turning them over in my mind as I walked down The Strand in London on a sunny day on my way to the BBC headquarters in Bush House, near Fleet Street. Some cynics say that the only reason for BBC popularity is that it is on the air more often and on more places on the dial than any other international broadcaster.

There is some truth to this, although the facts are not quite as above. The BBC ranks only fifth among international broadcasters for the amount of time on the air, per week. The USSR is first, followed by the US (Voice of America plus Radio Free Europe), the Republic of China (Radio Peking), and West Germany (Deutsche Welle). However, from the standpoint of pro-

grams in English that can be heard here in North America, the BBC does indeed lead all the others. You can hear the BBC round-the-clock in the US and Canada, and this beats such big North American broadcasters as the Voice of America, AFRTS (US Armed Forces Radio), and the popular CBC Northern Service in Canada.

It also is true that BBC programs are often "all over the dial" on your receiver. During many hours of the day, you can pick up their broadcasts on three, four, or even more different frequencies. This is because of its unusually strong transmission facilities—79 transmitters, 47 of them in four different locations in Britain and 32 in eight overseas relay stations, including the US, Canada, and the Caribbean. At certain hours, the Russians offer even more frequencies to the US listener, but only the BBC provides this multiband reception for most of the twenty-four hours.

While these technical advantages give the BBC a big boost over competition, they are not the only reasons for its popularity among listeners. The great reputation for world news coverage makes the BBC unique among international broadcasters. The BBC broadcasts more than 250 news programs a day from its headquarters in London. They are all prepared in an ultra-modern newsroom with electronic readout aids of all kinds, and with a staff that numbers over 100. It may be the world's largest newsroom and, at this writing, certainly the most modern as it was completed just over a year ago.

News is fed into this giant news machine by BBC correspondents from all over the world and by the international news agencies. Another important source is the famous BBC Monitoring Service. This BBC Division, located at Caversham Park, some 50 miles from London, provides round-the-clock reports on the contents of selected broadcasts from foreign radio stations. This supplements the agencies' and foreign correspondents' reports.

The BBC Monitoring Service provides a *Summary of World Broadcasts* every day and, in addition to sending

The control room at Bush House, London, home of the BBC External Services. World Service programs are broadcast 24 hours a day from these facilities in English and 38 other languages.

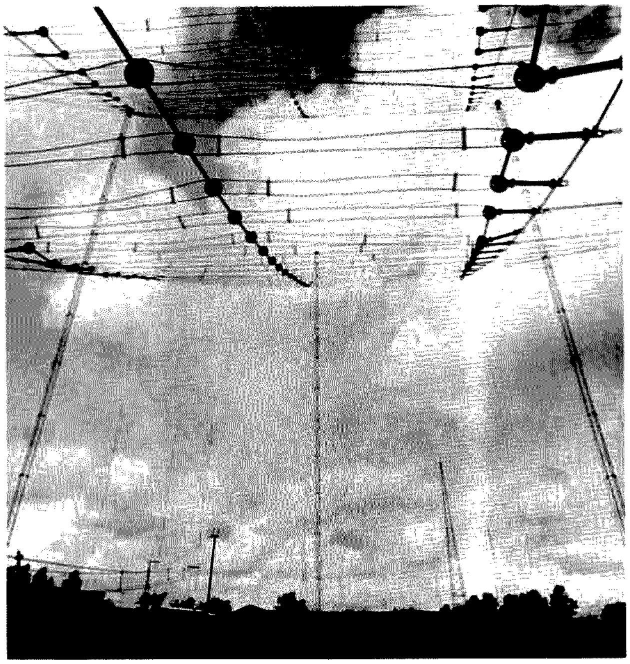
BBC AND THE FALKLAND ISLANDS CRISIS

BBC is at its best reporting on significant news events, and the Falkland Islands crisis certainly was a good example. First of all, the regular news broadcasts generally were an hour or so ahead of the wire services or what your local radio or TV station reported. You heard it first on BBC if you tuned it in. Second, BBC has special programs to deal with current newsworthy events, and the Falkland situation was no exception. On May 2, right after the air attack on the Argentine-held airfields on the Islands, the BBC preempted one of its most popular programs, Letter From America, for an interview with several military experts.

These special programs generally come right after major news programs such as their 1100, 2000, 0000, and 0200 GMT broadcasts, but they can come at any time, as the BBC thinks nothing of interrupting regular programs for something special.

Finally, the BBC has always had a special weekly broadcast to the Falklands on Sunday afternoon from 2209 to 2245 GMT on 9.915 and 12.040 MHz. I heard the one right after the Argentine invasion on April 4, and it was excellent. It included a message from the British Foreign Secretary, a review of British press opinions, and even special messages to relatives. The program was very easy to receive in the Northeast, where I reside. Check it out at the above times and frequencies.



A view of the antenna farm for the BBC's broadcasts to North America. The signal is loud and strong to the US.

it to the BBC News Staff, supplies it on a subscription basis to other governments, news agencies and newspapers, universities, research institutes, industrial and commercial organizations, and private individuals.

World news can be heard in North America seventeen times a day (see box). In addition, back-up programs on the world events are offered daily. Some of the most popular of these (as of last year) are:

- *Outlook*—an up-to-the-minute look at people, events, and opinions together with the latest UK news, sports, and weather.
- *Twenty-Four Hours*—analysis of the main news of the day plus reviews of the British press.
- *The World Today*—examines thoroughly one topical aspect of the international scene.
- *Commentary*—background to the news from a wide range of specialists.
- *Radio Newsreel*—news of events as they happen, and dispatches from BBC correspondents all over the world.
- *New About Britain.*
- *British Press Review*—Survey of editorial opinion in the press.
- *Financial News*—including news of commodity prices and significant moves in currency and stock markets.

In addition to these daily reports, the BBC also offers a number of weekly review-type programs on current events and special interest subjects. Among the most popular:

- *Financial Review*—a look back at the financial week.
- *Business Matters*—a weekly survey of commercial and financial news.
- *From Our Own Correspondent*—BBC reporters comment on the background to the news.
- *From the Weeklies*—a review of the British weekly press.
- *Listening Post*—a weekly survey of comment from radio stations around the world.

While the BBC has no rival for its extensive coverage of news, it also leads the way in many other types of programs—sport, drama, light entertainment, and music. These can be divided into two categories—monthly features and regular programs.

A typical month will have anywhere from 12 to 16 feature programs. These range from general interest to special interest subjects. Some are only for the "intellectuals," and others are for the "common man." In June, for example, the Queen's Birthday Parade (better known as "Trooping the Colours") is broadcast from London with all the music and pageantry you would expect. The BBC also has had weekly programs called " The Poetry of Europe," "The Movie Moguls," and "Medical Hypnosis."

Music is an important part of BBC programming. In fact, no other international broadcaster comes close to providing the number of musical programs—both classical and "Pops"—as does the BBC. Every month there are eight or nine special programs making their bows. Regular music programs include "Concert Hall," "Talking about Music," and a long-time BBC favorite, "The Pleasure's Yours," where Gordon Clyde plays classical requests. Another, "Classical Record Review," reports on new releases.

Classical music is not the only thing that the BBC provides listeners who dig instruments and vocal sounds. For the rock devotee, there is the weekly "John Peel" show where the host selects tracks from a newly released album and singles from the progressive rock scene in London. "Jazz for the Asking" is a popular weekly request show, and "Top Twenty" lets you listen to all the big hits. "Terry Wogan's Album Time" is a weekly show for those people who like the easy-listening kind of music, and there are many more of the same on the BBC every week.

Another area where BBC programming leads the way is in drama. There are four regular weekly features plus specials for the particular month. Total air time per week for this type of show is about 16 hours. A regular drama program is "Thirty Minute Theater." This often shows plays by such famous writers as Dorothy L. Sayers, Terrence Rattigan, and Oscar Wilde.

"Play of the Week," "Radio Theater," and "Short Story" are other regular drama programs.

SOME POPULAR BBC PROGRAMS
(All Times GMT)

Letter From America (Alistair Cooke)	Sundays 0545, 1115, 1645, 2315
Letterbox	Fridays 1415; Saturdays 2315; Sundays 0515, 2015
Look Ahead (Program Previews)	Daily 0940; weekdays 1943
In The Meantime	Thursdays 2120; Fridays 0150, 1115
Outlook	Weekdays 1900, 1515, 0115 (Tuesday-Saturday)
Anything Goes	Saturdays 1215; Mondays 0330, 0830
Concert Hall	Sundays 1515
Top Twenty (Hit Records)	Wednesdays 1830, 2330; Thursdays 1215
New Ideas	Saturdays 0530, 1015, 2230; Wednesdays 1725
Good Books	Saturdays 2015; Sundays 0215
Jazz For The Asking	Wednesdays 2130

Margaret Howard hosts the very popular "Letterbox" program on the BBC. Hear it on Fridays at 1415, Saturdays at 2315, or Sundays at 0515 and 2015 GMT.

Alistair Cooke is heard every Sunday on the BBC with his popular "Letter From America" program. Listen to it at 0545, 1115, 1645, or 2315 GMT.

Book lovers hear the following programs every week: "Book Choice," "Good Books," and "Paperback Choice." For those interested in science and hobbies, "Discovery" covers advanced developments in science, "New Ideas" gives you news of the latest British products and inventions of particular interest to the home owner and small businessman, "Science in Action" lives up to its name, and "Time Off" is a program devoted to hobbies, pastimes, and entertainment.

Religion is not overlooked at the BBC, either. Services broadcast from famous English cathedrals and churches can be heard on Sundays and Mondays. Two other programs are "Report on Religion," a weekly magazine of religious news and views, and a daily program called "Reflections."

Sports occupy a prominent part of the BBC weekly schedule, but a good many of these broadcasts are "very British indeed"—rugby, cricket, British football—and do not have a great appeal to the average US audience. If you have any British expatriates in your area, you can get them really excited by inviting them over to hear something like England versus Scotland in football.

BBC programs are very carefully researched by surveys and opinion polls. A Listener Panel (of which I am a member) is made up of 88% foreign nationals and 12% British expatriates and is asked to vote on individual programs and/or subjects on a regular basis. Panel voting accounts for the unusual number of drama programs and for the addition of a new business news program ("Financial Review," mentioned above). Over 50% of the panel apparently wanted more business news.

Research indicates that one of the most popular BBC weekly programs is Alistair Cooke's "Letter from America." Back in 1946, the BBC commissioned Cooke to deliver a series of radio talks on the subject of the USA where he had been living and working for more than a decade. The original plan called for thirteen weekly programs, but it has never stopped in all these years. It may well be the longest-running series in radio history. Listen to it on Sundays at 0545, 1115, 1645, or 2315 GMT.

One other BBC program that continues to score high marks is "Letterbox." This is a show where several people simply read letters (often complaints or suggestions for BBC programming) from listeners, and the BBC replies. On the surface, it doesn't sound very fantastic. However, the people on the show are so funny—with British wit and satire—that it has become one of the big BBC hits. Hear it on Fridays at 1415, Saturdays at 2315, and Sundays at 1515 and 2015 GMT.

At this point you might well be thinking about why the British go to all the trouble and expense of providing such a wealth of programs to the shortwave radio listeners of the world. To understand their motives we should examine the basics of the whole BBC foundation.

The letters "BBC" were first used in 1922 when the

British Broadcasting Company was formed and when regular daily broadcasts began. In those days, the BBC was a commercial organization, but one that operated under a license on conditions which would have prevented it—even if it wanted to—from turning broadcasting into a moneymaker for the shareholders. From the start, it placed the interests of the public above all. The result was that the British developed a genuine public service broadcasting system, paid for by its audience through their receiving licenses. In 1927, the Company became the British Broadcasting Corporation. It is a public corporation constituted by Royal Charter and holding a license from the Minister responsible for broadcasting. Thus the BBC is neither a government department nor a commercial concern.

The External Services, which is what we hear on our shortwave receivers, are an integral part of the BBC, operating under the same charter as the domestic service and sharing the same traditions. Unlike the domestic service (which is financed by annual "listener licenses"), the External Service is paid for by Parliamentary grants-in-aid. The government prescribes the languages which are broadcast and the length of time each is on the air, but editorial control rests with the BBC.

External broadcasting from Great Britain began in 1932 with a service in English. A few years later, the BBC was asked by the government to broadcast in other languages, the first of which was Arabic. During the early days of World War II, the BBC was a constant ray of hope for the people in France and other Nazi-occupied countries. I can well remember, as an airman shot down in France a few weeks before the invasion and hiding in a French farmhouse, listening to the BBC on the family radio. The BBC used to send coded messages to the French underground during those days.

Today, the External Services broadcast to the world in English and 38 other languages for over 100 hours every day. These programs originate mainly from the 52 studios in Bush House in London.

While the British Empire is no longer the world power that it once was and no longer has all those colonies on which "the sun never sets," it still has thousands of citizens and expatriates living abroad. The BBC brings information and entertainment from home and helps them keep their ties to the mother country. This, of course, is a prime objective of BBC broadcasting overseas.

Naturally, the BBC is interested also in presenting its own point of view to citizens of other countries around the world. The BBC estimates that about 75 million adults listen regularly (once a week or more) to its External Services. The English broadcasts are heard by about 25 million.

Like all international shortwave broadcasters, BBC programs and frequencies change from month to month. How can you keep up-to-date with these constant changes? Basically there are two ways to do it—by your radio receiver and by print. The BBC has three programs which will help you keep abreast of things. First is a show called "Look Ahead" which previews programs for each day. "In the Meantime" is a program which tells you what is new in BBC programs. And third, there is a program called "Waveguide" which covers frequency changes, propagation estimates, and other things which help you to keep tuned well to the BBC.

Serious listeners to the BBC will be interested in receiving a monthly copy of "London Calling." This publication is sent airmail from London every month, previewing programs and giving frequency changes so that the listener is right on top of BBC broadcasts a month ahead of time. Unfortunately, this is not a free publication and the cost to subscribers in the US is $13.00 per year. You can get a free sample copy, however, by writing BBC World Service, PO Box 76, Bush House, London WC2B 4PH. Or, to save yourself the cost of an overseas airmail stamp, direct your order to: British Broadcasting Corporation, 630 Fifth Avenue, New York NY 10019. ■

Active-Filter Design Made Easy

Using this BASIC program, if you don't like the design, then scrap it. All you lose is a few seconds.

B. E. Taylor WD4HPC
922 Reaves Street
Jackson MS 39204

There have been many articles on active bandpass filters in the electronics/amateur publications. Most of the articles are recipes, i.e., if you want my performance, duplicate my circuit. The rest have been tutorial articles which are mathematical in nature.[1,2] There is a section on multiple-feedback bandpass (MFB) filter design in the 1979 ARRL *Handbook*,[3] and there are at least two books devoted to active filter design.[4,5]

The equations used in designing the most common type of active bandpass filter—the second-order, MFB filter—can be solved nearly as easily as the name of the filter can be pronounced. The problem is that all of the design parameters and the component values are interdependent. Changing any one can lead to changes in others, which leads to more calculations.

This is just the sort of calculation that is ideally suited for computer evaluation. The program described in

Program listing.

this article was written to allow one to perform computer-aided design of second-order MFB filters.

The circuit diagram of an MFB filter is shown in Fig. 1. The labeling of the components is the same as that used in the program. The equations for performing the design are listed in Table 1. Most general-purpose op amps can be used in the filter.

This program has been written in such a manner as to be as versatile as possible. It should be helpful to the person wishing to design a filter of specified parameters and equally useful to the person who wishes to alter some parameter or component value in an existing MFB filter design. Take note: There are intrinsic limitations on the Q, gain, and center frequency of MFB filters which are not discussed in this article. The reader who is unfamiliar with these limitations should consult one of the references at the end of this article.

The program has seven possibilities for design, as follows:

1) Specify the values for R1, R3, and R5 in Ohms and C in uF. The program will calculate Q, G (the passband gain), and F (the center frequency, in Hz). This segment is useful in checking the parameters of a filter using the values of the available components.

```

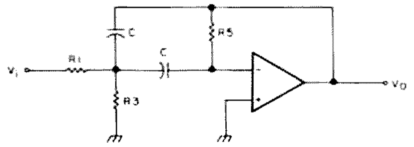

Fig. 1. Schematic of a second-order, multiple-feedback bandpass filter. The notation is the same as that of the program.

$$R1 = \frac{Q}{2\pi FGC}$$

$$R3 = \frac{Q}{2\pi FC(2Q^2 - G)}$$

$$R5 = \frac{Q}{\pi CF}$$

Table 1.

2) Specify the values of G, F, Q, and C. The program will calculate the values of R1, R3, and R5. Since resistors are usually more readily available than capacitors, this portion should be useful when the gain, Q, and center frequency are critical to the proper operation of the device.

3) Specify the values of R1, Q, F, and C. This segment is useful if one is trying to achieve a certain input impedance and the gain is not too critical.

4) This section allows one to change the center frequency of a previously designed filter by changing the value of the capacitors.

5) In this segment, one can change the center frequency by changing the value of the resistors.

6) This segment scales the impedance of the components in an MFB filter while retaining the same F, Q, and G. One chooses the new value for the capacitors and the program calculates the values of the resistors to maintain the same Q, F, and G. This is a useful feature if the desired values of C are not available and substitutes must be used.

7) This section allows one to predict the net Q and G of cascaded identical MFB sections. For example, three sections each of gain 2.0 and Q = 1.0 yield a net gain of 8.0 and a net Q of 1.96. Thus, there is a law of diminishing returns for the Q of cascaded sections. An unrealistic calculation shows that 120 cascaded sections each of Q = 2.0 would yield a net Q of 26.3!

The program has been written so that only the desired sections need be entered into the computer, in case a mass-storage device is not available. The program should run with no difficulty on any computer in which the BASIC has both floating-point arithmetic and string variables. Only minor modification would be needed to run the program on a machine that does not have string variables. This program has been run successfully on an 8K Pet.

To illustrate the use of the program, a sample printout has been included. It should be mentioned that several of the computer-generated designs were built on a breadboard and that the measured performance agreed very well with the theoretically predicted performance. ■

FILTER CASCADING

The most cost-effective way to improve the selectivity of any receiver – old or new – is to improve its IF filtering. A Fox-Tango Cascading Kit puts a high-quality steep-sided 8-pole filter in series with your present filter(s), both SSB and CW. The result is narrower Bandwidth and better Shape Factor, both of which dramatically reduce adjacent channel QRM – a necessity in today's crowded bands.

CONSIDER THESE KIT FEATURES
- Easy installation - 30 minute average.
- No drilling, switching, alignment.
- 16 poles of filtering yield:
  Filter Shape Factor as high as 1.19.
  Ultimate Rejection better than 100dB.
  Works wonders on SSB; improves CW.
- Compensates for Filter insertion loss.
- Complete instructions, clear diagrams.
- No RX audio impairment, TX unaffected.
- Includes Filter and all needed parts.
- Fits all models of Series - any letter.
- All Filters 8-pole – Guaranteed One Year.

SPECIFY KIT WANTED WHEN ORDERING

YAESU FT101 $75; FT101ZD $70; FT107 $75; FT901/2 $65; FR101 $55 (filter only). KENWOOD TS520/R599 $70; TS820 $70; TS830/R820 $150 (Two Filters). HEATH SB104A $60.

Shipping $3 (Air $5). FL Sales Tax 5%

In addition to the above, FOX-TANGO stocks a wide line of $55 SSB, CW, and AM 8-pole filters for Yaesu, Kenwood, Drake R4C and 7-line, and Heathkit. Also, special filters made to order. Send specs for quote.

ALL BAND TRAP ANTENNAS!

PRETUNED - COMPLETELY ASSEMBLED - ONLY ONE NEAT SMALL ANTENNA FOR UP TO 7 BANDS! EXCELLENT FOR CONGESTED HOUSING AREAS - APARTMENTS LIGHT - STRONG - ALMOST INVISIBLE!

FOR ALL MAKES & MODELS OF AMATEUR TRANSCEIVERS - TRANSMITTERS - GUARANTEED FOR 2000 WATTS SSB 1000 WATTS CW. INPUT FOR NOVICE ANO ALL CLASS AMATEURS! IMPROVED DESIGN!

COMPLETE AS SHOWN with 90 ft. RG58U-52 ohm feedline, and PL259 connector, insulators, 30 ft. 300 lb. test dacron end supports, center connector with built in lightning arrester and static discharge - molded, sealed, weatherproof, resonant traps 1"X6"- you just switch to band desired for excellent worldwide operation - transmitting and recieving! Low SWR over all bands -Tuners usually NOT NEEDED! Can be used as inverted V's - slopers - in attics, on building tops or narrow lots. The ONLY ANTENNA YOU WILL EVER NEED FOR ALL DESIRED BANDS - WITH ANY TRANSCEIVER - NEW - EXCLUSIVE! NO BALUNS NEEDED!

80-40-20-15-10-6 meter - 2 trap --- 104 ft. with 90 ft. RG58U - connector - Model 998BUC ... $89.95
40-20-15-10 meter --- 2 trap --- 54 ft. with 90 ft. RG58U - connector - Model 1001BUC $88.95
20-15-10 meter --- 2 trap --- 26ft. with 90 ft. RG58U - connector - Model 1007BUC $87.95

The Cornerstone of Equipment Failure: Heat Damage

The proper heat sink will preserve transistors. Learn how to keep your circuitry from resembling a core meltdown.

Kenneth H. Shamburger
1413 Glendale
Greenville TX 75401

Heat is a hazard to all electronics projects. Many electronics enthusiasts have experienced the displeasure of watching a prized project destroy itself with heat. Understanding heat transfer and heat-sink selection is necessary to avoid this hazard.

This article explains the fundamentals of heat-sink selection, which are easy to understand and apply. It begins with a review of the ways heat is transferred, explains how to calculate the temperature inside a semiconductor component, provides an example of heat-sink selection, and contributes some hints for interpreting semiconductor and heat-sink thermal specifications.

The Review

"Heat transfer" is more accurate in describing the removal of heat than "heat flow." The word "flow" limits the possibilities we associate with the phenomenon to a single action—such as water flowing. Heat is transferred by *three* mechanisms.

It is transferred by radiation as an electromagnetic wave. The heat transmitted from the sun through the vacuum of space to the Earth is an example of radiation.

Heat is transferred by conduction when two objects are in contact. A soldering iron melts solder by conduction.

Heat is transferred by convection when a fluid medium, such as air, moves across the surface of an object. The air drawn through the radiator of your automobile cools the radiator by convection. When air is blown across an object, it is called *forced* convection. But, the air surrounding a warm object will rise, causing cooler air to replace it without the aid of a fan. When air is allowed to circulate by heating, it is called *natural* convection.

Heat is transferred from semiconductor devices by all three mechanisms, as illustrated by the transistor in Fig. 1. It is radiated from the transistor chip to the case (a) and is conducted to the case where the substrate and case are in contact (b). The heat transferred to the case distributes itself throughout the case by conduction and, then, is transferred to the surrounding air by convection (c). If a heat sink is attached to the transistor, heat is transferred from the transistor case to the heat sink by conduction and to the surrounding air by convection. Also, it is radiated from the case and heat sink to objects nearby.

However, the amount of heat transferred by radiation is a small percentage of the heat transferred by convection. For this reason, the heat transfer equations typically used in heat-sink selection calculate only the heat transferred by natural convection. Similarly, the heat transferred by radiation from the chip to the case does not receive special attention in the calculations. And despite the inaccuracy, convenience makes us think of heat as flowing. These simplifications ease the analysis process.

Not all heat generated in the transistor is transferred to the air. Each segment of

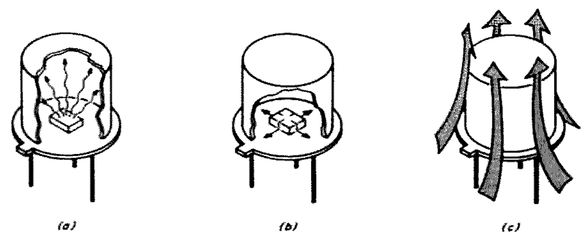

Fig. 1. Heat transfer from a transistor: (a) from chip to case by radiation; (b) from chip to case by conduction; (c) from case to air by convection.

the path between the chip and the air resists heat flow in a manner similar to a resistor resisting current flow. The heat retained in the transistor because of this impedance causes the temperature of the chip to rise. Our goal is to determine the temperature of the transistor chip. The chances of its destruction then can be evaluated.

The Fundamentals

In classical physics, equations have been developed for calculating the amount of heat transferred; they are not complicated. However, their solution depends upon parameters which are difficult to evaluate in practice. For this reason, engineers have devised equations which do not use these parameters, but which make heat flow analogous to electric current flow. In this analogy, a heat source is analogous to a current source, thermal resistance to electrical resistance, and temperature to voltage. The equation relating them is like Ohm's Law and says that *the difference in temperature (voltage drop) across a thermal resistance is equal to the thermal resistance multiplied by the heat (current) flowing through the resistance.* This thermal equivalent to Ohm's Law is expressed by the equation $T = \theta P$.

The symbol θ, with subscripts to indicate the circuit connections, commonly represents thermal resistance. For example, θ_{JC} is the thermal resistance between the transistor chip and its case. (The capital "J", for junction, is used widely to represent the source of heat in semiconductor components.) Values of thermal resistance for semiconductor components and heat sinks are usually obtained from their respective specifications. In an electronic component, heat originates as power dissipated by the device. The thermal analogy carries this into the electrical thermal model by making power, identified by a capital "P," equal to heat. (Sometimes the lowercase "q" is used to represent power because this symbol is used for heat in physics.)

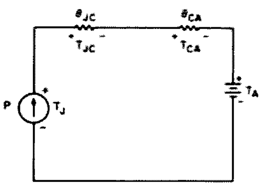

Fig. 2. Thermal circuit for a semiconductor.

The Calculations

Our goal is twofold. First, we must determine the temperature of the semiconductor chip. If this temperature exceeds a safe value, we must determine the thermal specifications for a heat sink which will provide adequate transfer away from the transistor. Using the electrical thermal analogy, the calculations involved in both tasks are similar to electric circuit calculations.

A diagram for the thermal circuit of a transistor is illustrated in Fig. 2. The unique feature of this diagram is the voltage source labeled T_A. This addition does not alter the validity of the model. The properties of the theoretically perfect current source (labeled P) do not allow current to flow backward through it. Since it is the only source of current in the circuit, the current flowing through the circuit equals P. The voltage source is simply a way of representing the temperature of the surrounding air (called the *ambient temperature*). It is convenient to include it so that the ambient temperature appears in Kirchoff's voltage equations for the circuit. Some people, choosing to account for T_A later in the analysis, do not include this source.

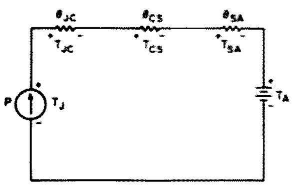

Fig. 3. Thermal circuit for a semiconductor with a heat sink.

A resistor represents the thermal resistance of each segment along the path between the semiconductor junction and the ambient. Each segment can be identified by the letters comprising its subscripts. Beginning at the junction, these are JC for junction-to-case and CA for case-to-ambient.

The thermal analogy for Kirchoff's Voltage Law says that the temperature of a semiconductor chip is equal to the sum of the temperature drops around the remainder of the circuit. This is expressed by the equation $T_J = T_{JC} + T_{CA} + T_A$, where T_J is the semiconductor chip temperature, T_{JC} is the temperature drop across θ_{JC}, T_{CA} is the temperature drop across θ_{CA}, and T_A is the ambient temperature. The values of T_{JC} and T_{CA} can be calculated from the thermal equivalent of Ohm's Law. Substituting these into the above equation, the junction temperature equation becomes $T_J = (\theta_{JC} + \theta_{CA}) P + T_A$.

Many times, a manufacturer specifies a value for θ_{JA}, which is the thermal resistance between the junction and the ambient. θ_{JA} is equal to the sum of θ_{JC} and θ_{CA} and may be used in the preceding equation instead.

A thermal circuit which includes the thermal resistances associated with a heat sink is illustrated in Fig. 3. The case-to-ambient resistance, θ_{CA}, has been replaced by two resistances, the case-to-sink resistance, θ_{CS}, and the sink-to-ambient resistance, θ_{SA}. When these are substituted for θ_{CA}, the equation for the semiconductor junction temperature becomes $T_J = (\theta_{JC} + \theta_{CS} + \theta_{SA})P + T_A$. A heat sink is selected on the basis of its θ_{SA}, which characterizes its ability to transfer heat into the surrounding air. To *determine* the largest value of θ_{SA} that will maintain a safe semiconductor temperature, the equation is solved for θ_{SA}. This yields the following equation: $\theta_{SA} = [(T_J - T_A)/P] - (\theta_{JC} + \theta_{CS})$.

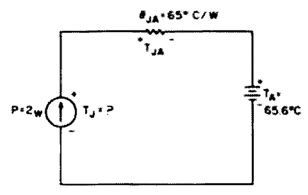

Fig. 4. Thermal circuit for the example without a heat sink.

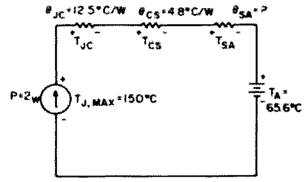

Fig. 5. Thermal circuit for the example with a heat sink.

An Example

Suppose you are designing an audio amplifier. You have estimated the power dissipation of the output transistor at 2 Watts. Having selected a transistor, you determine the relevant parameters from the transistor data sheet. These parameters are the maximum allowable power dissipation (P_{max}), the maximum operating junction temperature ($T_{J,max}$), the junction-to-case thermal resistance (θ_{JC}), and the junction-to-ambient thermal resistance (θ_{JA}). The values you found are listed below.

$P_{max} = 10$ Watts
$T_{J,max} = 150°$ C
$\theta_{JC} = 12.5°$ C/W
$\theta_{JA} = 65°$ C/W

Also, you note that the

Item 3: maximum junction operating temperature.

Item 4: specified thermal resistance θ_{JC}.

Item 6: derating curves for case and ambient temperatures.

Item 1: maximum power dissipation at specified case temperature and derating.
Item 2: maximum power dissipation at specified ambient temperature and derating.

Item 5: specified thermal resistance θ_{JA}.

MAXIMUM RATINGS

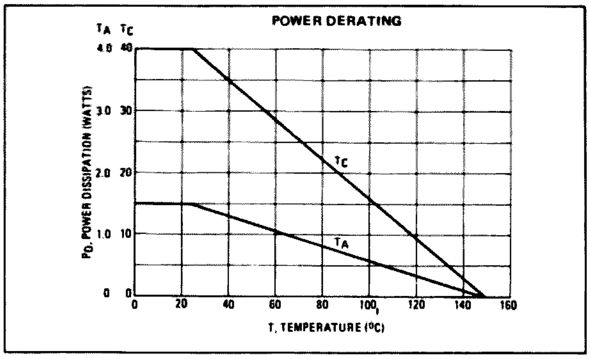

Fig. 6. Semiconductor thermal specifications and parameters.

transistor is in a TO-202 (plastic) case. In addition to these specified parameters, you have ascertained that the temperature of the air surrounding the transistor will not exceed 150° F (65.6° C). Good design practice suggests that you use a value between 10 and 20 percent greater than your estimated value for this temperature, as a safety factor, which you have done. (A diagram of the thermal circuit is shown in Fig. 4.)

Because your first concern is whether your transistor needs a heat sink, you use the value specified for θ_{JA} to calculate T_J as follows:

$T_J = (\theta_{JA})P + T_A$
$T_J = (65)2 + 65.6$
$T_J = 195.6°\ C$

The calculated value of T_J is greater than the specified maximum operating junction temperature ($T_{J,max}$) by 45.6° C.

The next step is to determine the thermal resistance required of the heat sink. This is accomplished by solving the equation for θ_{SA} after substituting the value of $T_{J,max}$ for T_J. However, the value of one other parameter, the case-to-sink thermal resistance, θ_{CS}, must be determined before this equation can be solved. θ_{CS} depends upon the method used to mount the transistor. It usually is provided in a table by heat-sink manufacturers and, occasionally, semiconductor manufacturers. Table 1 lists values of θ_{CS} for some common transistor case types and mounting methods.

After obtaining a value of 4.8° C/W for θ_{CS}, the completed thermal diagram is shown in Fig. 5. θ_{SA} is calculated as follows:

$\theta_{SA} = [(150 - 65.6)/2] - (12.5 + 4.8)$
$\theta_{SA} = 24.9°\ C/W$

A heat sink with a thermal resistance of 24.9° C/W or less will provide adequate heat transfer. A number of small, inexpensive heat sinks with a θ_{SA} of 20° C/W for the TO-202 case style are available. You simply select one which meets your mounting requirements.

Case Style	Metal-to-Metal Dry	Metal-to-Metal Lubricated	Insulated Dry	Insulated Lubricated
TO-3	0.5	0.1	1.3	0.36
TO-66	1.5	0.5	2.3	0.9
TO-83	—	0.1	—	—
TO-94	—	0.1	—	—
TO-126	2.0	1.3	4.3	3.3
TO-127	1.6	0.8	2.6	1.8

The Semiconductor Specs

Except for saying that they are found in the manufacturers' data sheets, details of how the values for thermal resistances are obtained have not been discussed. Yet determining these values from the specifications sometimes requires skill. Familiarity with the types of data most likely to appear in the data sheet is necessary to success. With the aid of the data sheet appearing in Fig. 6, this data and its interpretation are described in the following paragraphs.

The data sheet in Fig. 6. was chosen to illustrate common methods of specifying semiconductor thermal specifications for two reasons. First, all of the specifications are labeled clearly and are arranged into a single, logical area of the specification. This is not true of all semiconductor data sheets. Often, thermal specifications, particularly for linear integrated circuits, are placed in notes. (The entire data sheet should be read before concluding that they have been

omitted.) The second reason for selecting the data sheet shown in Fig. 6 was that it contained all of the data relating to thermal specification. A typical data sheet will provide only a portion.

Thermal resistance is specified by direct specification, by derating, and by thermal-related parameters. A manufacturer uses direct specification when he tabulates thermal resistance in data sheets. The designer simply inserts the specified values into his thermal equations. Items 4 and 5 of Fig. 6 illustrate direct specifications.

A derating specifies how quickly the maximum power dissipation must be decreased as the case or ambient temperature increases. A derating may be given by statement (illustrated by items 1 and 2) or by curve (illustrated by item 6). A numeric value for thermal resistance is needed for the thermal analysis. The technique for determining a number from this kind of specification is more easily explained using an example.

The derating (item 1) indicates that the 2N6034 has a maximum power dissipation of 40 Watts at a case temperature of 25° C. It also indicates that this should be derated at 0.32 W/°C above 25° C. The derating is assumed to be linear above the specified temperature unless otherwise specified. This means that for every degree increase in case temperature, the dissipated power must be decreased by 0.32 Watts.

An examination of the electrical thermal model in Fig. 2 causes us to conclude that the power has to be decreased because junction-to-case thermal resistance is limiting heat flow from the device. Furthermore, the rate at which the power must be decreased as the temperature increases is related to the value of this thermal resistance. Actually, *the rate of derating is the reciprocal of the thermal resistance.* Thus, the junction-to-case thermal resistance for the 2N6034 can be calculated:

$\Theta_{JC} = 1/0.32$

$\Theta_{JC} = 3.125°$ C/W

The same technique can be applied to determine the junction-to-ambient thermal resistance from the derating in item 2.

The type of thermal resistance specified is indicated by the location of the specified temperature. The subscript attached to the temperature symbol identifies this location.

Frequently, a manufacturer will provide a derating curve, such as the one illustrated in Fig. 7, which provides the same information in graphical form. The horizontal axis indicates temperature. In this curve, it is temperature at the case. The vertical axis is the maximum dissipated power allowed at the indicated temperature. To find the thermal resistance from a derating curve, divide the difference in temperature by the difference in dissipated power. From Fig. 7, the temperature changes from 25° C to 150° C, which is 125° C. The change in dissipated power over this temperature range is from 40 Watts to 0 Watts, a difference of 40 Watts. Thus, Θ_{JC} is calculated by dividing 125 by 40.

$\Theta_{JC} = 125/40$

$\Theta_{JC} = 3.215°$ C/W

Notice (in item 6 of Fig. 6) that Motorola gave a derating curve for both case and ambient temperatures. Each curve is labeled with the appropriate temperature.

A manufacturer may not specify either a thermal resistance or a derating. However, a knowledgeable designer can determine a derating specification from other specifications and calculate the thermal resistance from this derating.

The key to determining a derating curve for a semi-

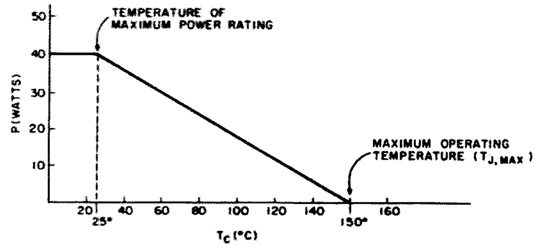

Fig. 7. Transistor power derating curve.

conductor is to find two points of the curve above the temperature where it begins to slope downward. Among other parameters, the derating curve specifies the temperature above which the device can no longer be operated, that is, $T_{J,max}$ (see Fig. 7). At this temperature, the power must be zero. This is equivalent to saying that the current must equal zero in the electrical thermal circuit (Fig. 2).

Because no current is flowing in the circuit, no temperature is dropped across either Θ_{JC} or Θ_{CA}. Thus, the maximum operating temperature of the device must equal the maximum operating ambient temperature and the maximum operating case temperature. When the manufacturer specifies $T_{J,max}$, one point on both the ambient and the case temperature derating curves is known. The second point on the derating curve is established as the temperature where the maximum power dissipation is specified.

For example, the following are specified for the 2N6034 (items 1 and 3).

$P_{max} = 40$ Watts@$T_C = 25°$ C

$T_{J,max} = 150°$ C

The fact that this data agrees with the derating curve can be verified by comparing these two points on the derating curve labeled T_C in Fig. 6, item 6. Though Motorola seems to specify P_{max} as part of the derating specification, the appearance is created by the organization of the data sheet. The common practice is to specify that parameter, though no derating is specified.

Typically, the values of thermal resistance calculated from the derating curve and from the power and temperature specifications will agree with the specified thermal resistances within a few percent. Have you calculated Θ_{JA} by the above methods to find how closely they agree to its specified value?

As a designer searches for thermal specifications, he will discover that either Θ_{JA} or Θ_{JC}, but not both, is specified for a number of devices. Also, these specifications will be void of data which allows calculation of the unspecified value. This is true because manufacturers specify the parameters they believe relevant to the use of the device being specified, as they understand its application. In this regard, a device may fall into one of three categories.

It may have a specific function and the designer is not expected to concern himself directly with the power dissipation versus temperature relationship. For example, an SN7400 TTL quad NAND logic gate has a specific function. In this case, the manufacturer specifies the maximum temperature of operation for the device. The designer is expected to limit the ambient temperature to a value such that the specified value is not exceeded.

A device may be designed for use with or without a heat sink. These devices,

AT LAST!

This service will be available nationally. Lab tested & time proven modifications professionally installed in your amateur Handy-Talkie 2M, 220, 440, MH2 transceiver by Henry Radios warranty technicians (KNOWN AS "A&W PRODUCTIONS")

HAVE ALL PL TONES AVAILABLE AT YOUR FINGER TIPS

Outboard the dip switch! Have it neatly inlayed into the back cover of your Handy-Talkie making all 32 PL Tones Selectable at a moment's notice.

$25 Got your own PL? Send it to us with your Handy-Talkie unit and we do the professional installation for you.

$55 We will install a new PL and inlay the dip switch into the back cover of your Handy-Talkie ready to operate.

Send us your Handy-Talkie unit and a check or money order plus $3.50 for shipping and handling payable to **A&W PRODUCTIONS, INC.**

For **TEMPO** units the dip switch is inlayed into the Push-to-Talk bar. The **TEMPO S-15** will have the dip switch inlayed into the back cover.

$45 We will install a **NEW BATTERY BEATER** in your **TEMPO S-1, S-2, S-4, S-5 READY** to operate. Your New Battery Beater will use the same jack as the charger with no new holes and regulation circuits built into unit. Comes with Cigar Lighter Adapter with internal fuse.

CONTACT A&W PRODUCTIONS FOR SPECIAL MODIFICATIONS YOU MAY WANT TO HAVE DONE. WE SPECIALIZE IN THE TEMPO HANDY-TALKIES.

WE ARE AN OFFICIAL "TEMPO" REPAIR STATION

being rated between 0.25 and 5 Watts dissipation without a heat sink, usually are classified as small or intermediate power devices. An example is the 2N6034 Darlington used in the above examples. Both Θ_{JA} and Θ_{JC} are specified for these devices.

Lastly, a device may be classified for use only with a heat sink. These are the high-power devices, such as the 2N3055. The data manuals commonly provide only the data required to determine the heat-sink requirements.

The Heat-Sink Specs

Values of thermal resistance for heat sinks are more easily determined from data sheets than are those for semiconductors. Thermal resistance for a heat sink can be provided by either of two methods. The first is by direct statement, as in the case of semiconductors. The second method is by curve, as illustrated in Fig. 8. The horizontal axis is heat as power dissipated. The vertical axis shows the temperature difference between the heat sink and ambient caused by the heat flow. To find the thermal resistance, simply find the temperature difference caused by the heat flowing in your thermal circuit. Then, divide the temperature difference by that power.

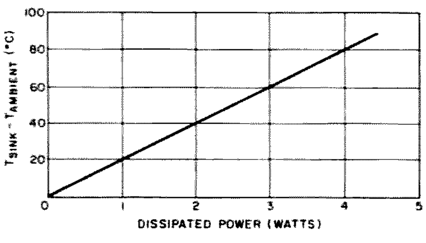

Fig. 8. Heat-sink thermal rating curve.

In the example where we calculated Θ_{SA}, the audio output transistor dissipated 2 Watts. The curve in Fig. 8 shows a temperature difference of 40° C at a 2-Watt power dissipation. Thus, the thermal resistance is:

$\Theta_{SA} = 40/2$

$\Theta_{SA} = 20°\ C/W$

Sometimes, the thermal resistance curve is nonlinear, meaning that Θ_{SA} changes as the dissipated power increases. Thus, it will not be a straight line, as shown in Fig. 8. Usually, it is straight. In either case, this technique determines Θ_{SA} easily.

All manufacturers provide curves with essentially the same data. The only difference is the axis labeling. For example, IERC labels the vertical axis on some of their data sheets "maximum sink temperature rise above ambient (°C)." To avoid confusion, simply remember the thermal equivalent of Ohm's Law: A temperature difference is caused by heat flowing through a thermal resistance.

One other factor must be considered during heat-sink selection. The thermal resistance of a heat sink is specified for a specific physical orientation of the heat sink. (This is true of semiconductors, also.) Except for heat sinks which are designed for special applications, the manufacturer specifies the resistance for *maximum unobstructed natural convection*. To understand the meaning of this, recall that natural convection depends upon heated air rising to be replaced by cooler air. A heat sink operates properly when air can circulate freely across the maximum area of every fin. This means that it should be mounted with its fins vertical. Also, the ends should be kept clear to allow unobstructed entry of air between the fins at the bottom and exit from the top. *Your mounting constraints should always be considered during heat-sink selection.*

Summary

The principles involved in heat-sink selection are now complete. The thermal circuit and its electrical equivalent provide a theoretical model for easy analysis of thermal phenomena. Thermal resistances for an equivalent circuit are determined from the manufacturers' data sheets. Applied to the thermal circuit, Ohm's Law and Kirchoff's Voltage Law, which are understood by those who work with electrical circuits, allow calculation of the semiconductor junction temperature. The calculated temperature is compared to the maximum temperature specified by the manufacturer to determine the necessity of a heat sink. If a heat sink is required, the maximum semiconductor temperature is substituted into the equations to determine the maximum thermal resistance for a heat sink which will limit the junction temperature to a safe value.

Two criteria are used to select a heat sink: Its thermal resistance must be less than the calculated maximum value and its mounting must be consistent with the designer's application. Heat-sink selection using these criteria completes the process.

Your January Home-Brew Project

No frills—just a solid $10 SSB exciter for HF. Who says hams don't build anymore?

Promises, promises. How can any SSB exciter be inexpensive when an i-f filter is needed? I have been regaled with plans for inexpensive SSB generators, but the operative paragraph usually describes how the filter was found deep in the bowels of the faithful junk box or bought for a song from an unsuspecting entrepreneur at the last flea market. I have always arrived just as the last treasure has been sold. The promise of an inexpensive exciter eluded me.

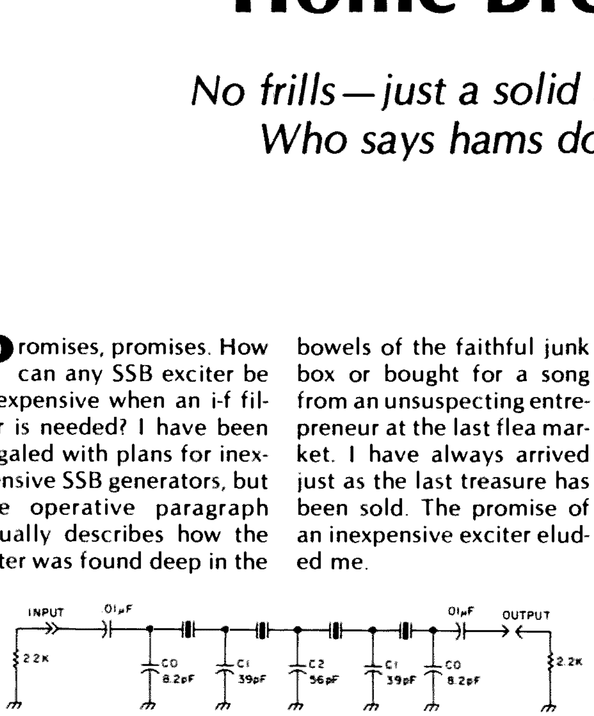

Fig. 1. A 3.58-MHz crystal-lattice SSB i-f filter with an audio bandwidth of 2 kHz and 2.2k input and output impedance.

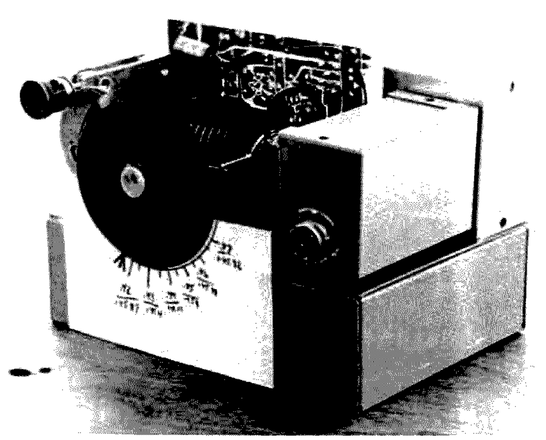
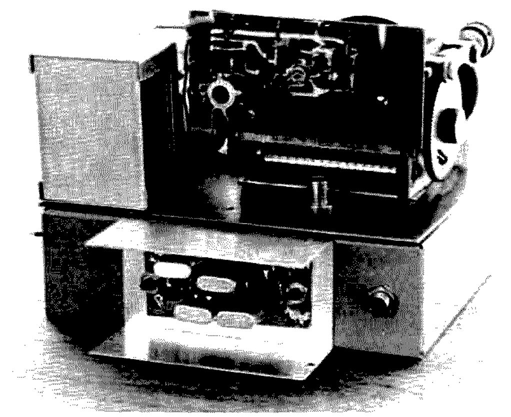
So what am I offering you? Another inexpensive SSB exciter. This time the operative paragraphs will describe how you can make a very satisfactory crystal i-f filter for less than $10.00 which needs no critical tuning or messy and unpredictable crystal grinding. I will then describe how I used it in a 15-meter exciter.

This simple filter is made using four of the ubiquitous 3.58-MHz television crystals in a ladder configuration as shown in Fig. 1. If all you want is a simple i-f filter, this could be built as described by the schematic and you would be pleasantly impressed by its performance. For those who are innovators and have other crystals which are the same in frequency, there are general design rules for making two-, three-, and four-crystal filters. Fig. 2 gives the normalized capacitance values for these. To find the actual value of



The prototype 15-meter SSB exciter.



The exciter displaying the crystal filter mounted in a minibox for shielding.

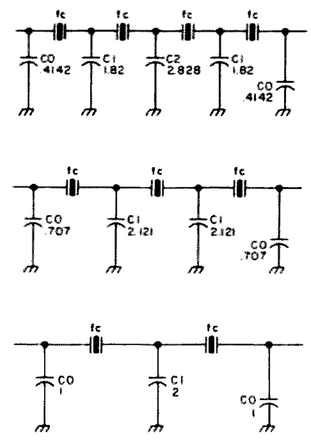


Fig. 2. To find the actual value of the shunt capacitors, multiply the coefficient beside each capacitor by 1/(2πfR), where f is the crystal frequency and R is the filter design impedance.

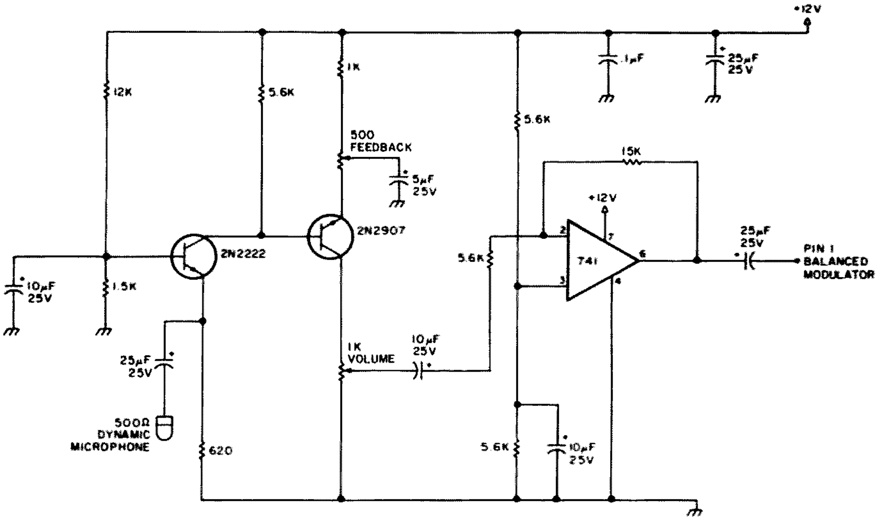

Fig. 3. Microphone amplifier.

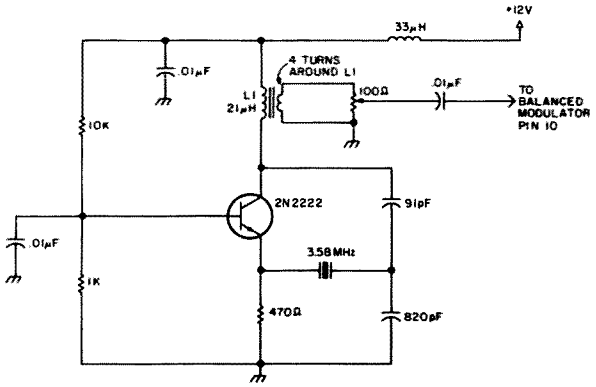

Fig. 4. Carrier oscillator. All resistors are ¼ Watt. L1 could be Miller part 46A225CPC with a 4-turn secondary added, available from Radiokit, Box 411H, Greenville NH 03048.

each capacitor, the coefficient beside each capacitor must be multiplied by 1/(2πfR) where f is the resonant frequency of the crystals in Hertz and R is the design input and output impedance in Ohms. For the suggested filter using the 3.58-MHz crystals, R was chosen to be 2.2k Ohms—thus 1/(2πfR) = 20 pF. C_0 = .4142 × 20 pF = 8.284 pF = 8.2 pF; C_1 = 1.82 × 20 pF = 36.40 pF = 39 pF; C_2 = 2.828 × 20 pF = 56.56 pF = 56 pF.

If the impedance was chosen to be 1.8k Ohms, then C_0 = 10 pF, C_1 = 47 pF, and C_2 = 68 pF. Thus, the impedance which is chosen to work toward is flexible, but there are a few considerations to notice. As the impedance is lowered, the passband of the filter is reduced and the insertion loss will increase. On the other hand, as the impedance is increased, the passband widens but the ripple in the passband also increases. As well, the low capacitance values for higher impedances make stray capacitance more troublesome.

This technique has been used by others to make filters using surplus crystals in the 8-to-12-MHz ranges as well. It was stated that a design impedance of 800 to 1000 Ohms was usable at that frequency for an SSB filter. A design impedance of 1500 Ohms was usable at 5 MHz.

In putting this filter into a circuit, it is imperative that it be properly terminated in its design impedance, both on the input and output. Neglecting this can give a very high passband ripple.

Now, you may think, we have the filter, but there is always a need for carrier-oscillator crystals. Good news! The series resonant frequency of the crystals controls the lower limit of the passband, so one more crystal identical to those used in the crystal filter will allow selection of the upper sideband. How easy can it be?

Listening to OSCAR 8, mode A has whet my appetite for a taste of operating through this satellite. One constraint seems to be that one should have full-duplex capabilities for the most success, but I had no VHF equipment and only one HF transceiver. I built a simple transmitting converter with five Watts output on 2 meters for one-milliwatt input on 15 meters. This gave me VHF capability. I first proposed to excite this with a CW signal; then the idea of a DSB exciter was entertained before I discovered the inexpensive crystal filter just described. I then could proceed with a full SSB exciter with an output power of one milliwatt on 15 meters. The design philosophy was very simple—I used the parts I had easily available to build a basic transmitter without bells and whistles. This was done and I am happy with the results.

Microphone Amplifier

The microphone amplifier described in Fig. 3 must match a low-impedance dynamic microphone to a low-impedance, balanced-modulator input while increasing the microphone output of 2 mV to one volt. The first stage is a common base amplifier to take advantage of the low input impedance and high voltage gain of this configuration. This directly drives a common emitter amplifier with adjustable feedback in the emitter to control the gain of this stage. The output stage is the common 741 operational amplifier, used for its very low output impedance which easily drives the 100-Ohm audio input of the balanced modulator. If you have other microphones, you will need different amplifier circuits than this. Just remember to

use a low-impedance output circuit to successfully drive the balanced modulator.

Carrier Oscillator

The crystal-controlled Colpitts oscillator (Fig. 4) was chosen as the carrier oscillator because it is very easy to get operating and the crystal vibrates in its series resonant mode. The output is terminated in a 100-Ohm variable resistor which allows for the adjustment of the carrier level for best carrier suppression in the balanced modulator. Inductor L1 was found in a Poly Paks assortment and a four-turn secondary was added. Miller part 46A225CPC also could be used for L1.

Balanced Modulator

This is the popular MC1496 double-balanced modulator which, when built with reasonable care, works very well (see Fig. 5). The first one was built on the same PC board as the crystal filter, but the resulting 30-dB carrier suppression was disappointing. With proper shielding of the carrier oscillator and crystal filter, this suppression was increased to a usable 50 dB. The balanced-modulator output is greater than is needed by the carrier mixer and also greater than can be passed by the filter. With this in mind and having a need for a resistive input-filter termination, the balanced modulator is output into a resistive pad, the value of which is chosen to give maximum linear conversion mixer output without limiting while retaining maximum carrier suppression.

Carrier Mixer

The 3.58-MHz single-sideband output of the crystal filter must be converted to the desired 21.5-MHz band to be usable. In order to properly terminate the filter and provide impedance conversion, an FET buffer amplifier is included which drives the 600-Ohm input of the TL442 balanced mixer (Fig. 6). This integrated circuit was chosen as it uses few biasing components and has good carrier suppression without balancing controls. If desired, the MC1496 could be used with equally good results if the TL442 is hard to find.

With this situation in mind, a carrier mixer was built using the easily found MC1496 double-balanced mixer. I had good success with it as well. This mixer circuit, shown in Fig. 7, is almost identical to the balanced modulator. R1, between pins 2 and 3, was made variable, enabling me to set the gain of the stage and thus control the drive to my transmitting converter. The output was made single-ended instead of balanced, so I could use the same tuned circuit as was used for the TL442 mixer. The input drive circuit was made a source follower to properly match the lower input impedance of the new circuit. The SSB drive level into the mixer is adjusted so that the maximum input does not cause the output

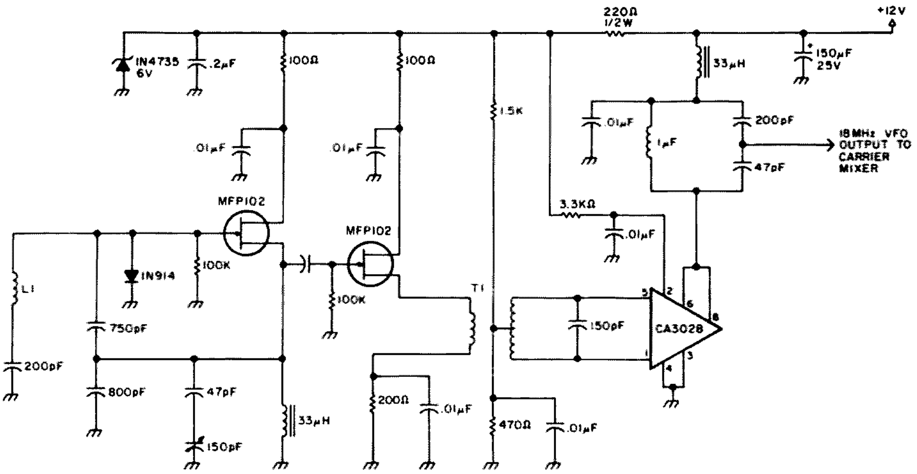

Fig. 9. Vfo. L1: 23 turns of #22 enameled wire close-wound on 3/8″-diameter ceramic form. T1: Primary—25 turns #34 enameled wire on Amidon toroid T25-6; secondary—28 turns center-tapped #34 enameled wire wound over primary.

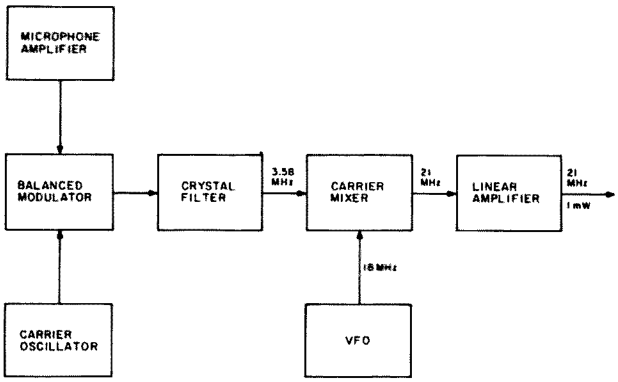

Fig. 10. Block diagram of exciter.

to limit. The output is adjusted by R1 to properly drive the PA stage, and the carrier null potentiometer is adjusted for minimum vfo output. Usually it will be sufficient, in this service, to set the null pot at its midpoint. Carrier suppression is less critical here than in the balanced modulator.

Linear Amplifier

The linear amplifier (Fig. 8) supplies about 1 milliwatt output, sufficient to drive my transmitting converter to full output. An input series trap tuned to 14 MHz was included to reduce the level of the undesired mixer product (probably an unnecessary frill but, having the parts, it was easy to include). If greater output is desired, the collector-base negative feedback could be reduced or more stages of amplification included.

Vfo

The variable frequency oscillator (Fig. 9) is the series-tuned Colpitts or Clapp oscillator driving a push-push doubler to provide an 18-MHz carrier for the conversion mixer. The doubler is made with a CA3028 differential amplifier with its outputs in parallel.

Building Ideas

This exciter was built in the modular configuration which allowed for engineering changes at a whim (also called mistake rectification), and many ideas were tried as I went along. All circuits were put on printed circuit boards as this makes for neat construction. The vfo and carrier oscillator are on single-sided board and the others are on double-sided board. I also put the carrier oscillator and the crystal filter in their own shielded enclosures to reduce the carrier feedthrough, interconnecting the units with RG-174 coaxial cable and audio-cable connectors. A block diagram of my exciter is shown in Fig. 10.

Many parts values may be questioned, and I assure you that I would not argue for their absolute value. My choice has been controlled very much by availability. I had some 1-uH variable inductors bought from Digital Research Corporation of Texas, a bag of assorted inductors and chokes from Poly Paks, some dipped-mica capacitors removed from surplus boards, and assorted resistors.

What I had was used to design circuits that would do the job without my buying every component as a special part. For example, bias circuits can usually be changed if the voltage division provided remains the same. Tuned circuits are flexible because resonance is controlled by both L and C and both can be changed to meet your needs. Amidon Associates can supply a flyer containing a very accurate chart for winding inductors on their various toroid cores if you have a particular capacitor you want to use in a resonant circuit. Bypass capacitors can be chosen from many values which will effectively provide a short to ground for the signal frequency. A command transmitter capacitor was used to provide vfo tuning, but any

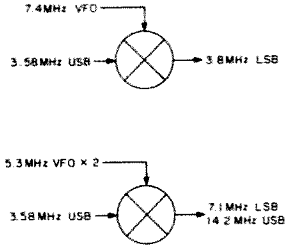

Fig. 11. Suggested conversion schemes for amateur-band exciters.

comparable variable capacitor would do just as well. The transistors used are common, inexpensive, and easily substituted with something you may have on hand.

Ideas

This crystal filter and single-sideband generator could be used in many other ways (see Fig. 11). Using a vfo frequency of 7.3 MHz would give a lower sideband output on 75 meters. Doubling the output of an auxiliary 5-MHz vfo would provide an upper sideband signal on 20 meters or a lower sideband signal on 40 meters. Many refinements are also possible which would make this exciter more versatile, but even without them it is possible to have an exciter with a quality single-sideband filter for very little.

The following parts may not be listed by advertisers, but they usually can supply them:

- MC1496—Godbout Electronics, Jameco Electronics.
- TL442—Active Component Sales Corp., Box 1035, Framingham MA 01701.
- CA3028—Aldelco. ■

A Breakthrough

for Amateur and Commercial Repeater Users.

DIVERSITY RECEPTION—the ability to add a second receiver to your repeater system—can now be a reality for even the small user. The Pegasus VS-2 will allow your repeater to "listen" to two receivers simultaneously and to noiselessly switch between receivers as often as necessary to adjust for fading and nulls. This is particularly useful for repeaters that wish to provide coverage for hand held users or where receiver desense is a problem. You supply the second receiver & RF link and the VS-2 does the rest. Complete instructions and diagrams included with the VS-2.

NEW TS830S for $150?

Yes indeed! Just add a Matched Pair of top-quality 2.1KHz BW (bandwidth) Fox Tango Filters. Here are a few quotes from users:

"... Makes a new rig out of my old TS830S!..."
"...VBT now works the way I dreamed it should..."
"...Spectacular improvement in SSB selectivity..."
"...Completely eliminates my need for a CW filter..."
"...Simple installation - excellent instructions..."

The Fox Tango filters are notably superior to both original 2.7KHz BW units but especially the modest ceramic 2nd IF; our substitutes are 8-pole discrete-crystal construction. The comparative FT vs Kenwood results? VBT OFF—RX BW: 2.0 vs 2.4; Shape Factor: 1.19 vs 1.34; 80dB BW: 2.48 vs 3.41; Ultimate Rejection: 110dB vs 80. VBT SET FOR CW at 300Hz BW — SF 2.9 vs 3.33; Insertion Loss: 1dB vs 10dB.

AND NOW A NEW TS 930S!
Tests prove that the same filters improve the '930 even more than our '830. Don't buy CW filters—not even ours. You probably won't need them!

INTRODUCTORY PRICE: (Complete Kit)...$150
Includes Matched Pair of Fox Tango Filters, all needed cables, parts, detailed instructions. Specify kit desired: FTK-830 or FTK-930.
Shipping $3 (Air $5). FL Sales Tax 5%

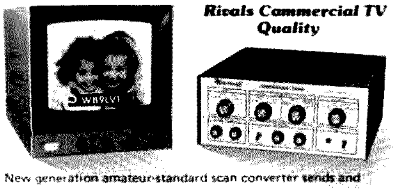
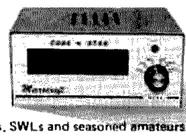
VIDEOSCAN 1000 - HIGH RESOLUTION SSTV
Rivals Commercial TV Quality



New generation amateur-standard scan converter sends and receives sharp pictures with up to 16 times better resolution than earlier units. Three scan rates, optional call sign and much more. Easy to use. Amateur, phone line TV, surveillance, teleconferencing, etc. Free "How To Get Started In SSTV".
Kit: VS-K $595.00 Wired: VS-F $795.00 Shipping: $6.00

CODE★STAR - ALL MODE CODE READER
More Features Per Dollar Than Anything Else!



Ideal for novices, SWLs and seasoned amateurs. Built-in code-practice oscillator and speaker. Copies Morse, RTTY and ASCII. Large LEDs. Easy to connect and operate. Automatic speed tracking. Excellent digital/analog filtering. 12VDC or 120VAC with AC adapter provided. Compact. 2lbs. Connect computer (like VIC-20)/printer with optional ASCII output port.
Kit: CS-K $159.95 Wired: CS-F $219.95 Shipping: $5.00
ASCII Port: Kit: CS-IK $59.95 Wired: CS-IF $79.95

MORSE-A-KEYER — CW Keyboard Kit: MAK-K $159.95 Wired: MAK-F $199.95 Shipping: $5.00

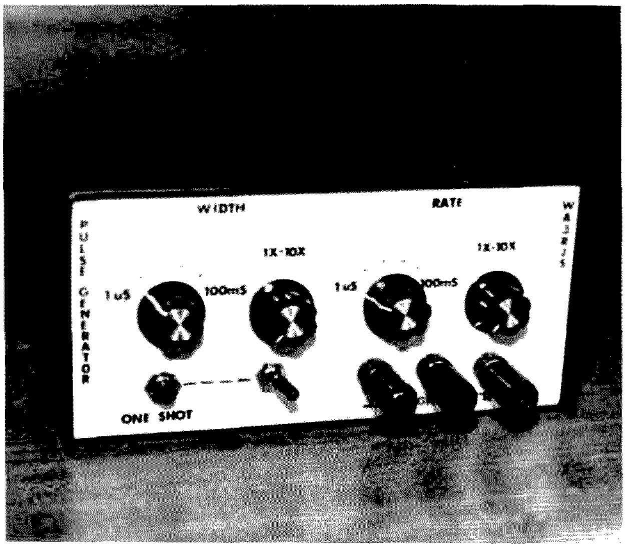
King of the Pulse Generators

One-shot or a train, TTL or CMOS, this generator will fit the bill. It's just what your test bench always wanted.

Ronald A. Miara WA3RJS
8803 Enfield Court, #22
Laurel MD 20708

This handy pulse generator is built around two commonly available under-a-dollar ICs. Both pulse width and repetition rate are continuously variable over six decade ranges from one microsecond to one second. Normal and inverted pulse train outputs are available, and a one-shot feature allows the user to output a single pulse by depressing a front-panel push-button switch. The outputs are TTL and 5-V-dc CMOS compatible.

To operate the generator, the desired repetition rate range is selected with switch S1. (Repetition rate is the time between the occurrence of each pulse and is equal to the reciprocal of the frequency of the pulse train.) The ranges that may be selected by S1 are: 1 µs, 10 µs, 100 µs, 1 ms, 10 ms, and 100 ms. Variable resistor R1 is then used to tune the repetition rate between one and ten times the range value selected by S1. For example, if S1 is set to 10 µs and R1 is set to 1X (fully



Pulse generator.

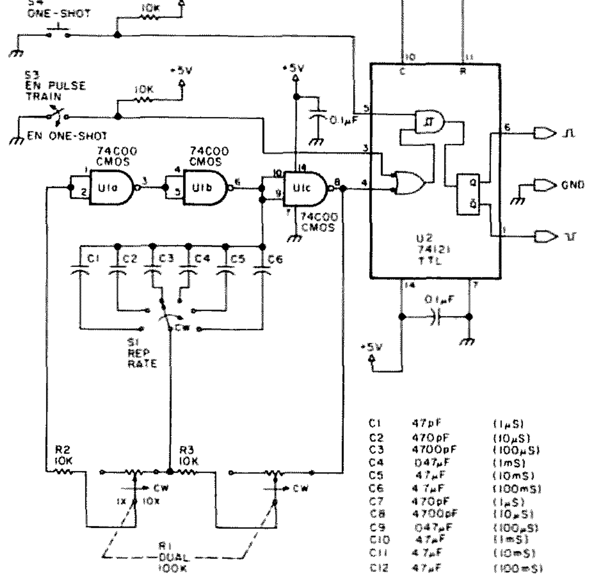


Fig. 1.

counterclockwise), a pulse will occur every 10 μs. R1 may then be tuned up to ten times this value (10X, fully clockwise), in which case a pulse will be output every 100 μs.

Pulse width is similarly set with S2 and R4. S2 selects the same range values as S1, and R4 is used to tune the pulse width from one to ten times the value selected by S1. Pulse widths with duty cycles up to 90% may be set up. (Duty cycle is defined as the ratio of time the pulse is on to the time of a complete cycle, times one hundred. An ordinary square wave would then have a 50% duty cycle since it is on half the time of a complete cycle.)

To use the pulse generator as a one-shot, switch S3 is closed, disabling the output pulse train. Push-button switch S4 is then depressed and released to output a single pulse from U2.

Refer to the schematic (Fig. 1) to understand how the pulse generator works. Three NAND gates in U1 are configured with capacitors C1 through C6, variable resistor R1, and resistors R2 and R3 to form a square-wave oscillator. The frequency of this oscillator determines the repetition rate of the generator. The resistors were chosen to produce repetition rates in convenient decade ranges. The oscillator drives one-shot generator U2. Capacitors C7 through C12, variable resistor R4, and resistors R5 and R6 determine the width of the pulses output from U2. The values of these resistors and capacitors were also chosen to produce pulse widths in decade ranges. Since the oscillator driving U2 causes pulses to be output at a periodic rate, the output of U2 becomes the output of the pulse generator.

Construction of this unit is not critical. Short lead lengths and an all-metal enclosure should be used to ensure a clean and stable pulse-train output. U1 (74C00) should be CMOS, not TTL, to ensure that the oscillator will work. The accuracy of the pulse width and repetition rate depends on the tolerance of the resistors and capacitors used and how carefully the front-panel multiplier controls are labeled (from 1X to 10X). Since I normally use an oscilloscope to set up my pulse generator, I used simple front-panel labeling and rely on the scope for calibration of the pulse train. Simple front-panel labeling also keeps the cabinet size small since less space is required on the front panel. My unit is powered by four penlight batteries which drive a miniature three-terminal +5-V-dc regulator IC (LM309H).

The small size and low cost of this handy pulse generator should make it a nice addition to any ham's workbench. ■

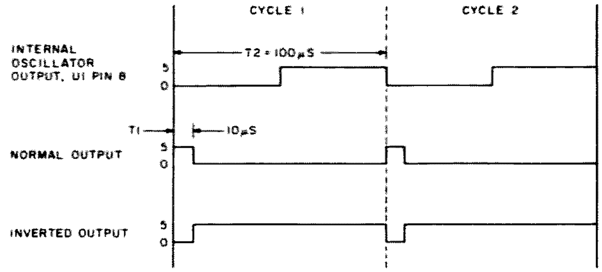

Fig. 2. Pulse generator timing diagram. This shows a pulse train which has a 10-μs pulse width and a 100-μs repetition rate. The duty cycle is equal to 10 μs divided by 100 μs times one hundred percent, which equals 10 percent.

SATELLITES

Late September brought amateur satellite enthusiasts something to cheer about for a change. On the 20th, the University of Surrey amateur scientific satellite (UoSAT) was rescued from oblivion when ground controllers managed to turn its telemetry beacons off for the first time since April. By the time you read this, UoSAT may already be back in full operation.

The trouble with UoSAT (also known as UoSAT-OSCAR 9 or, more simply, UO-9) began when both the 2-meter and 70-cm beacons were accidentally commanded on at the same time. The effect was to desense both receivers aboard the bird, making it impossible for UoSAT to "hear" instructions from the ground. Even the massive 26-dB-gain 2-meter EME array of K1WHS proved insufficient to break through.

After an enormous expenditure of time and effort, the spell was finally broken on 70 cm when the UoSAT salvage team obtained the services of a little-used 150-foot dish antenna at SRI International in California. With a gain at 70 cm of 46 dB and an erp approaching 12 megawatts, the big dish did the trick, though not without practically being rebuilt by the UoSAT gang in the process.

Fortunately, UoSAT seems none the worse for the experience. The satellite, which does not carry communications transponders, continues to send a steady stream of scientific data earthward. In addition to telemetry beacons at 145.825 and 435 MHz, look for HF beacons at 7.05, 14.002, 21.002, and 28.510 MHz. An on-board TV camera may be activated as well.

Ever since the failure of the European Space Agency (ESA) Ariane rocket during its fifth flight (September 9), the date for the launch of AMSAT's Phase IIIB satellite has been anyone's guess. The best bet is now sometime in mid-April, assuming no further problems arise.

Thanks to AMSAT *Satellite Report.*—Jeff DeTray WB8BTH, *73* Staff.

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

ZERO-DISTRICT QSO PARTY

Starts: 2000 GMT January 8
Ends: 0200 GMT January 10

Organized by the Mississippi Valley Radio Club. Stations outside of zero district will work zero stations only, zeros may work any station. The same station may be worked once on each band and each mode. However, mobile stations may be worked each time they change counties.

EXCHANGE:

RS(T) and ARRL section. Zero-district stations also must send county.

FREQUENCIES:

3560, 7060, 14060, 21060, 28060, 3900, 7270, 14300, 21370, 28570, 3725, 7125, 21125, and 28125.

SCORING:

Multiply the number of zero-district counties by the number of contacts. Zeros score by adding ARRL sections, zero-district counties, and DXCC countries worked and then multiplying by total contacts.

ENTRIES & AWARDS:

Certificates will be issued to all entrants who submit a log and an SASE. Endorsements will be given for the high score in each ARRL section, DX country, and Novice/Technician Class. Mail logs by February 15th to: WØSI, 3528 W. Columbia, Davenport IA 52804. Include an SASE for log forms or results.

WORLD COMMUNICATION YEAR

Starts: 0001 GMT January 15
Ends: 2400 GMT January 15

On November 19, 1981, the United Nations General Assembly adopted a resolution proclaiming 1983 a "World Communication Year: Development of Communications Infrastructures." The basic objectives of the WCY are: (1) to provide the opportunity for all countries to undertake an in-depth review and analysis of their policies on communications development, and (2) to stimulate the accelerated development of communications infrastructures. The Potomac Valley Radio Club is sponsoring this contest in support of the World Communication Year.

All licensed radio amateurs worldwide are eligible to participate. There will be two categories: single operator and multi-operator. Both categories are mixed-mode. Only stations using one transmitter are eligible for an award. The same station may be worked once on each band. Telephony (including SSTV) and Telegraphy (including RTTY) emissions count as separate bands. No cross-emission contacts are allowed. The main objective is to contact as many other amateurs as possible, anywhere in the world, using 1.8 MHz to 275 GHz, excluding the 10-, 18-, and 24-MHz bands.

EXCHANGE:

All stations will send their ITU region and their ITU zone. For example, the following stations would send the listed exchanges: DL1AA, 128; W1AAA, 208; and JA1AAA, 345.

SCORING:

QSO points are 4 points per QSO outside your ITU region, 2 points if inside your ITU region but outside your zone, and 1 point if inside your ITU zone. The multiplier is the number of ITU zones worked on each band. For final score, multiply the total QSO points for all bands by the total zones worked for all bands.

AWARDS:

A plaque will be awarded to the high-scoring station of each category (single- and multi-operator) in each of the three ITU regions. A certificate will be awarded to the high-scoring entrant of each category in each ITU zone. In addition, a certificate will be awarded to one UHF/microwave station of each ITU zone judged to have displayed the most outstanding achievement. Members of PVRC may not receive awards.

ENTRIES:

All entrants are to use a suitable log form and summary sheet of their choice. Logs should include times in GMT, bands, calls, complete exchange, and QSO points for each QSO. Multipliers should be clearly marked in each log. Cross-check sheets (dupe sheets) are required if more than 200 QSOs are made on any band.

Summary sheets should be a single page and show number of QSOs, QSO points, zone multiplier for each band, and the total score. The summary sheet must contain the entrant's callsign, region, zone, name, and address. Multi-operator stations must list the name and call (if any) of each operator. Entries for the special UHF/microwave award should be indicated on the front of the summary sheet with a description of the basis of the UHF/microwave award written on the back of the summary sheet.

Entries must be postmarked by February 28th and mailed to: PVRC, PO Box 337, Crownsville MD 21032.

Each entrant agrees to be bound by the provisions of the rules, by the regulations of his licensing authority, and by the decisions of the Amateur Radio Activity Awards Committee. An entry may be disqualified if the overall score is reduced by more than two percent. An entry will be disqualified if more than two percent of duplicates are left in the log. A penalty of 8 QSO points will be assessed for each duplicate QSO or for each miscopied callsign or exchange found by the awards committee.

HUNTING LIONS IN THE AIR CONTEST

Starts: 1200 GMT January 15
Ends: 1200 GMT January 16

The contest is sponsored by Lions Club International and coordinated by Lions Club Rio de Janeiro Arpoador, Brazil. Participation in the contest is open to all duly licensed radio operators, Lion and non-Lion. There are two modes: phone and CW. Participation in both modes is allowed but points are counted separately. All amateur stations participating must operate within their licensing regulation. Separate categories will exist for single operators and radio clubs/societies. Multi-operators may participate, but each prefix must be listed on the log.

Use all bands, 80 through 10 meters. Only one QSO with the same station on each band may be counted. Remember that phone and CW are counted separately!

EXCHANGE:

RS(T) and sequential QSO number. When a contact is made with any Lion,

The RaRa Rag

NEWSLETTER OF THE MONTH

Beauty is not just skin deep. At least, not in the winner of this month's newsletter contest, *The RaRa Rag*, published by the Rochester Amateur Radio Association.

The thoroughly professional look of *The Rag* includes typeset and printed text, with even margins on both sides, headlines, cutoff lines, and clean graphics. It is all printed in booklet format on heavy paper.

But the beauty doesn't stop there. *The Rag's* contents go way beyond the usual list of upcoming events, meeting dates, and president's message. One extra feature of the newsletter is "Cop's Corner," which keeps members posted on local street construction and emergency service.

For history buffs, there is "*The RaRa Rag* 20 Years Ago," and to bring the reader up to date, the editors have included news shorts from the *W5YI Report* and other news services. Other features include news of the club's various special interest groups, a fitting forum for what appears to be an exceptionally active club.

Congratulations to Editor Ronald Jakubowski K2RJ and his staff for putting together a club newsletter that reads as good as it looks.

To enter your club's newsletter in our contest, send a copy to: Editorial Offices, *73*, Peterborough NH 03458.

VOLUNTEERS NEEDED

How would you like to be on the "inside" of a major amateur-radio contest? Here's your chance!

We're looking for volunteers to become members of the *73* Contest Committee. Anyone with an interest in contesting and a willingness to work hard is welcome. Committee members will help with the following:

1. Contest rules and ethics
2. Forms and correspondence
3. Log checking and scoring
4. Filling out and mailing awards

Heading up the contest committee is KE7C. Please drop him a note (with SASE) and let him know you can help. Write to Bill Gosney KE7C, *73* Contest Committee, 2665 North Busby Road, Oak Harbor WA 98277.

We want YOU on the *73* Contest Team!

Leo, or Lioness, the name of the club contacted should be clearly identified.

SCORING:

QSOs within the same continent count 1 point while those between different continents count 3 points. Score 1 extra bonus point for each QSO with a member of a Lions Club, Leo Club, or Lioness Club and 5 points for a QSO with a member of the Lions Club Rio de Janeiro Arpoador. Contacts between Brazilian stations will count only 2 extra points. Contacts between members of the Arpoador club will not count any bonus points.

AWARDS:

For single-operator entries the Lions Club International will present trophies for first, second, and third place on both modes. Fourth through tenth places will receive plaques. A trophy will be presented to the first-place radio club/society on both modes. In addition, each log sent by participants with a minimum of 5 contacts will receive a special certificate. The contest committee will also select and award the most active Lions Club participating in the contest.

ENTRIES:

Keep a separate log for each mode. Each participant will note in the logs the callsign and information exchanged. Confirmation of contacts will be made by comparing the logs of the participants. Participants should send their logs by air mail not later than 30 days after the contest to: Contest Committee, Hunting Lions in the Air, Lions Club of Rio de Janeiro Arpoador, Rua Souza Lima #149, Apt. 402, 22081 Rio de Janeiro, RJ, Brazil.

MICHIGAN QRP CLUB CW CONTEST

Starts: 1500 GMT January 15 Ends: 1500 GMT January 16

This is a CW-only, all-bands (160-10-meter) QRP contest sponsored by the Michigan QRP Club. The contest is open to all amateurs and all are eligible for awards. General call will be "CQ QRP DE..." Each station will be competing within their own state, province, or country in one of three categories: 1) one Watt or less of output power, 2) five Watts or less of output power, and 3) over five Watts of output power.

EXCHANGE:

RST, QSO number, and power output.

SCORING:

Each contact is worth one QSO point. Multiply total QSO points (all bands) by the number of states, provinces, and countries worked per band for total points. If using emergency power (100% natural and 100% battery) then apply a 1.5 bonus multiplier.

AWARDS:

Certificates will be awarded to the highest-scoring stations in each state, province, or country.

ENTRIES:

Log information must include: full log data with a separate log for each band, name, address, equipment used, and power output. Logs must be received by the contest manager no later than six weeks after the end of the contest. W/VE stations please send an SASE, all others please send 2 IRCs if contest results are desired. Address all entries to: Contest Manager, Michigan QRP Club, 281 Crescent Drive, Portland MI 48875.

THE NORTH DAKOTA QSO PARTY

0000 to 0800 and 1600 to 2400 GMT January 22, 0800 to 1600 GMT January 23

Sponsored again by the Red River Radio Amateurs of Fargo, North Dakota. Work stations once per band and mode.

EXCHANGE:

RS(T) and state, province, country, or North Dakota county. Novices, please indicate Novice status.

FREQUENCIES:

Phone—1835, 3905, 7280, 14295, 21380, 28580.

CW—1810, 3540, 7035, 14035, 21035, 28035.

Novice—3725, 7125, 21125, 28125.

SCORING:

Phone contacts count 10 points, CW 20 points, and RTTY 50 points. North Dakota stations count an additional 100-point bonus for working five Novices. North Dakota stations multiply score by total of states, provinces, and countries worked (max 53).

ENTRIES & AWARDS:

Certificates to state, province, and country winners. Plaque to North Dakota winner and highest scorer outside North Dakota. Mail logs by February 28th to: Bill Snyder WØLHS, Box 2784, Fargo ND 58108-2784. Include a large SASE for results.

TEXAS QSO PARTY

Starts: 0000 GMT January 22 Ends: 2400 GMT January 23

Sponsored by the West Texas Amateur Radio Club of Odessa, Texas. Use all bands and modes. Each station may be worked again upon each county change. Single-operator entries only. CW QSOs must be in CW subbands only.

EXCHANGE:

QSO number (beginning with 001) and state, province, country, or Texas county.

FREQUENCIES:

Novice—3710, 7110, 21110, 28110.

Phone—3940, 7260, 14280, 21370, 28600.

CW—3565, 7065, 14065, 21065, 28065.

SCORING:

All non-Texas stations score points as follows: Phone contact with fixed station in Texas—1 point. CW contact with fixed station in Texas—2 points. Phone contact with mobile station in Texas—5 points. CW contact with mobile station in Texas—7 points. Multiply by the number of Texas counties worked (254 max).

All Texas stations score 1 point per contact on phone, 2 points on CW regardless whether fixed or mobile. Multiply by the number of states, countries, and Canadian provinces worked.

AWARDS:

Plaques to top scores: US, US Novice, DX, Canada, Texas fixed, Texas mobile, Texas Novice. Certificates to top score in each state, country, and province. Certificates also to top 10 Texas stations. Special awards as activity dictates.

ENTRIES:

All logs must be received by March 15th. Mail entries to: WTARC, PO Box 9944, Odessa TX 79762-0041.

RESULTS

THE 1ST ANNUAL 40/80 PHONE CONTEST —A TREMENDOUS SUCCESS—

"Truly unbelievable, it was fantastic, like catchin' fish in a barrel..." Those were the words and phrases echoed by nearly every contestant in *73*'s First Annual 40- and 80-Meter Phone Contest. There is little doubt that this event will remain on the contest calendar for many years to come. We are grateful to those who made it all happen!

After the dust had finally settled, VE5DX became the World 40-Meter Phone Champion for single-operator stations. Congratulations to you Jim, a superb performance. I4YNO and company firmly took the World 40-Meter Championship for the multi-operator category. Fantastic job, fellas!

On 80 Meters, I3MAU is the World Single-Operator Phone Champion, and the group at N9NC tied down the winning score to take the world multi-operator title. Fabulous scores for such a difficult band.

Combining both the 40- and 80-meter contest scores, CN8CO became the 1982 Low-Band Champion for single operators while VE2ZP and crew took top honors in the multi-operator category. Take a look at the scoring summary, to see an impressive job by two top-notch stations.

Who made the most contacts, you ask? Among 40-meter single ops, VE5DX made 972 QSOs, followed by KK9A (856) and W9RE (851). In the 40-meter multi-op standings, N9NB was credited with 1098 QSOs, followed by a distant second, KD4TO, with a demanding 972 contact total. On 80 meters, considering band conditions, the competition was just as fierce. N7DF from Utah tallied 700 QSOs for the single-operator category, while VE5XK accumulated 672 contacts on the band. In the 80-meter multi-operator class, N9NC and crew mustered 793 contacts with VE2ZP (597) and W4CN (564) trailing.

Looking at the combined contest scores for both bands, N7DF turned in 1188 QSOs with 931 QSOs registered by second-place finisher KC4OV in the single-operator category. For multi-ops, VE2ZP recorded 1271 QSOs followed by N4BAA of Florida with 1066 contacts.

Was the band open? Well on 40-meters the following stations turned in 30 or more DX country multipliers: I4YNO (59), I5MPK (44), YV5ANE (44), W9RE (41), N3AMK (40), VE5DX (39), VE2ZP (38), CN8CO (38), JA2BAY (35), LX1JX (35), N4BAA (33), N9NB (31), and KJ9D (31). As expected, the 80-meter DX totals were somewhat less with the following stations scoring 20 or more DX multipliers: I3MAU (58), CN8CO (53), KQ2M (39), DA1RE (34), WB2DHY (30), I5MPK (29), N4BAA (28), KØCS (28), DF9ZP (27), ZF2DX (27), N7DF (24), JA1ELY (22), AK1A (22), and OK1KZ (22).

One of the most interesting aspects of tallying any contest is the opportunity to summarize the equipment used by competing stations. Every year brings new surprises.

Which antenna dominated on which band? Naturally the wire (economy version) array led the pack. Look at the statistics:

40-Meter Antennas		80-Meter Antennas	
Dipole/inverted vees	39.8%	Delta loop	11.1%
Monoband vertical	11.6%	¼-wave sloper	11.1%
Delta loop	9.3%	Full-wave vertical	8.3%
Trap vertical	9.3%	Trap vertical	8.3%
2-element yagi	7.0%	Phased verticals	5.5%
¼-wave sloper	4.6%	3-element wire yagi	5.5%
2-element delta loop	4.6%	Inverted-L	2.7%
2-element wire beam, bobtail curtains, 2-element quads, 3-element yagis, and phased verticals	2.3% each	2-element delta loop	2.7%

Of all the stations that turned in entries, 28% declared that they were running completely "barefoot" while 2% stated that they were running 500 Watts, 15% were running a kilowatt, and a dramatic 55% were radiating two kilos! What were they using as exciters? 39.7% of the contestants claimed to be running Kenwoods, 21.3% were running Yaesu gear, 22.4% were operating Drake equipment, 6.5% were Collins, while the remaining 10.1% were divided amongst Ten-Tec, Icom, Heathkit, Tempo, and yes, even home-brew equipment.

So what does all this add up to?... a debut not to be forgotten, an event full of surprises which left a lasting impression on all who witnessed this two-day extravaganza.

This brings us to the second annual event which is just around the corner. Look for the 40- and 80-meter contest announcement in last month's issue of *73*. This year the event is being split into two separate parts. The World 40-Meter Phone Championship will be held on January 8, while the World 80-Meter Phone Championship event is scheduled for the following day, January 9, 1983. Each promises to become a record breaker in its own right. For all the details, send your SASE directly to the official contest address, attention Billy Maddox, 468 Century Vista Drive, Arnold MD 21012.

So start pruning your antennas. I intend to work each one of you on both bands so mark the dates on your calendar. Get on the band right now and begin telling other amateurs about the contest, especially the DX stations. Pitch in and pass the word! Good luck in the contest.

Continued

40/80-METER CONTEST SOAPBOX

"Glad to take part, even if it was just a little bit. Really enjoyed it!"—N1BMV.
"Lots of fun. Am going to try 80 meters next year."—KA1CDC.
"Super contest. . . I know I'll be back next year!"—WA1ZAM.
"Too many carriers and foreign broadcasts on 40!"—KA2HTH.
"My first contest ever. Really enjoyed it and am looking forward to next year."—WB2IWJ.
"The gang here had a blast."—KF2X.
"Fine contest but I suggest limiting the action to the general portion of the band."—N3AWS.
"Would have liked to have participated more. Look for me again next year."—W3ICM.
"You've got another winner!"—K3IXD.
"Great contest—lots of great contacts were made on the 40 this weekend."—KF3M.
"Hope to get a vfo and increase my multiplier total. Sure enjoyed the contest."—KC3N.
"Enjoyed the contest and, once and for all, recognized the District of Columbia as a separate multiplier!"—W3USS.
"Good propagation at times. Fantastic turnout. Should be a classic event."—N4BAA.
"Great contest with lots of potential as the years go by."—N4UH.
"Had a very good time and worked some new states."—N5AFV.
"TNX for sponsoring this enjoyable contest. Had a great time on 40."—N5CPO.
"Whooee, quite an event!"—KC5NQ.
"Learned a lot about my station. Looking forward to next year."—WB5YWO.
"Better to have the 40-meter test on CW rather than SSB."—N6JM.
"A very good contest. Not much heard during the daytime."—W6YMH.
"Thanks for staging this contest. I enjoyed it immensely. Hope to be back next year to improve the score."—KA7AKQ.
"Where were the VEs? Great stateside turnout!"—N7DF.
"Where were the JAs?"—KB7G.
"Let's do it again next year!"—AK7J.
"Great contest and I'll be back next year!"—K7PGL.
"Fine contest idea, thanks to 73. Lots of activity on the bands. Wish there was more DX on 40."—N8ATR.
"Damn fun despite the tremendous big guns. I'll give it a shot again next year."—KC8GN.
"Very successful debut. Good time of year too! See you next year for sure!"—W8VEN.
"I seem to have scored very well. Lots of good contacts to be had."—KK9A.
"Everyone involved has my congratulations. I wish all contests were this much fun."—KJ9D.
"Surprised at the number of stations on the 40-meter band. Broadcast stations really got fierce! Will try 80-meters next year."—K9FMR.
"Bands were in great shape. Had a great time."—KB9TI.
"Activity and band conditions were excellent. Korea on 15 was a new one for me!"—KØCS.
"Great contest. Nice to work a contest that doesn't take up all weekend. Family-man special!"—WAØIDK.
"Excellent contest. Definitely will be back next year."—KØUK.
"WB4OXZ and I found it rough going on 80. Worth every minute of it though. Had a ball."—C6ADV.
"Definitely should become one of the biggies! Unbelievable participation for a first time event!"—CN8CO.
"Fun contest. I'll tell more Europeans about it."—DL8UI.
"I know why CW is beautiful now—very hard on phone with 50 Watts. There's always next year."—G3WKS.
"My first touch of 40- and 80-meter contesting and I loved it."—H44SH.
"Marvelous contest though conditions weren't the best for me. Am looking forward to next year."—HI8GB.
"Nice contest indeed. We hope to do better next year."—I4YNO.
"Very good contest. Not much activity in JA-land on contest."—JA1FFY.
"Lots of activity on 40-meters but not many Europeans. See you again next year."—LA5YF.
"Good propagation but no Europeans in the contest. Maybe next year it will get more attention."—LX1JX.
"Very good idea to establish this contest. Hope more Europeans hear about it! See you next year."—OK2BLG.
"Thanks for the contest, a very good idea. Enjoyed 80 meters."—OX3ZM.
"Didn't work a single North American station."—PA3AZM.
"Nice contest with good propagation. Wish W/VEs would listen below 3.800 MHz. Very strong in Europe!"—SM4CAN.
"Great contest and is sure to grow as it gets more publicity."—VE1AJJ.
"Thoroughly enjoyed the contest. Very well conceived, very well attended—a definite winner!"—VE2ZP.
"Appreciate the contests. 80 was very difficult with 20+ static. USA stations forget we can only work 3.5-3.7 on phone."—VK5BW.
"Very little activity in Romania. Maybe advertisements will help."—YO4BXX.

W9RE AND W8NGO
160-METER WORLD CHAMPIONS

"The most activity ever heard on 160" . . . "Best contest I've ever operated" . . . "An absolute winner!" . . . "Definitely will try again next year." These welcome comments were heard again and again in the wake of 73's 1982 "top-band" event. "Wrapped up my Worked All States" . . . "Thanks to the contest I worked another new country!" These were some of the rewards earned for just a few hours of contest operation by nearly 1500 participants.

If you're a supporter of 160 meters, you can't help but notice how much the contest has grown since its inception some 3 years ago. The bright future of this world-championship event seems assured.

Year	Participants
1980	569
1981	917
1982	1482

This year, W9RE single-handedly produced 1118 QSOs, 58 states and provinces, and 8 DX counties to become the 1982 World 160-Meter Phone Champion for single-operator stations. Mike managed to beat second-place finisher and 1981 World Champion W8LRL by a margin of 136 QSOs and 20,000 points. A race as close as this, involving two of the most prominent stations on the band, sets the stage for our 1983 event just around the corner. The upcoming contest will decide the best two out of three.

Both W9RE and W8LRL are to be congratulated for their superb performance in our own "survival of the fittest." Who will surpass W9RE's 1118 QSOs which now establishes a world record on 160?

In the multi-operator category, the crew members at W8NGO are the 1982 World Champions. They compiled 877 QSOs, 56 states and provinces, and 4 DX countries for a total score of 273,900 contest points. The gang at W4CN, last year's World Championship station, finished second with a total of 238,950 points. It was a very close race for the top slot, with only 73 QSOs and 1 multiplier separating the two stations. Here again, the 1983 contest will decide the best two out of three, since last year's champions finished second this time.

Of all the single-operator entries, the following stations compiled 500 or more QSOs: W9RE (1118), W8LRL (982), WB3GCG (932), WD8CRY (762), WBØCMM (722), W1CF (697), KJ9D (622), N8ATR (582), N5JB (579), KC8P (561), K9OLL (552), W3BGN (524), and N5CG (502).

In the multi-operator class, 500 or more QSOs were earned by the following stations: W8NGO (877), W4CN (804), AK2E (688), K9ZUH (677), W9ZX (512), and K9YUG (504).

W9RE worked the most states and provinces (58) for the single-operator class, followed by W8LRL and WB3GCG with 57; K9RJ with 56; KC8P, WD8CRY, KJ9D, N5JB, WBØCMM, and K9OLL with 55; W1CF, W9DUB, and WØCM with 54; N5CG, W4VKK, KB8HW, and W2FJ with 53; K1MNS, W5YZ, KAØHIG, and KA7BTO with 52; and KC4OV, KØSTF, WA2GZB, N7DF, and K1LPS with 51 W/VE multipliers.

For the multi-operator category, W8NGO, K9YUG, and K9ZUH accumulated the most W/VE multipliers, with 56 each; AK2E had 54, W4CN had 53, KØUK had 52, and W9ZX had 51 states and provinces.

Screening all logsheets, EA5ET worked 17 DX countries, followed by G3XWZ/A with 15 countries; W8LRL with 13; N4IN, OK1AVG, and W1CF with 12; WB3GCG and VE1YX with 11; and ZF2DX with 10.

After all the contest entries have been tabulated, it is rewarding to analyze the station equipment and antennas used by the participants. The tables below tell the story.

Equipment	Usage
Kenwood	38.5%
Yaesu	27.0%
Drake	20.5%
Icom	4.9%
Ten-Tec	3.3%
Collins	2.4%
Hy-Gain, Astro, Heath, Signal One	.85% each

Equipment used in the 160-Meter Phone Contest.

Antenna	Usage
Dipole/Inverted vee	37.3%
Inverted-L	15.3%
¼-wave sloper	9.3%
Trap vertical	9.3%
Shunt-fed tower	7.9%
Vertical (½, full wave)	7.9%
Long wire	5.7%
½-wave sloper	2.8%
Quad, delta loop, 5-element yagi, windom, zepp	.9% each
Receive antennas only:	
Beverage	10.7%
Loop configuration	1.9%

Antennas used in the 160-Meter Phone Contest.

The success of this very popular contest would not have been possible without the dedication of two superb gentlemen of the "gentleman's band." Our special thanks to Dan WA2GZB and Ed K3IXD who both tackled the responsibilities of scoring all the entries and corresponding with the entrants. These gents have been involved with this world-championship contest ever since its founding some three years ago. Both have burned the midnight oil countless nights when the rest of us were enjoying the openings on the band.

The 4th annual contest is just around the corner. After you read these results, pass them on to your friends on 160. Be sure they're aware of our world-championship contest, scheduled for January 15-16, 1983. If you think this year's scores were record breakers, wait until January 1983! With the relaxation of the FCC rules on this band, we expect to see nearly 2,000 stations participating. I'll be there, how about you?

160-METER CONTEST SOAPBOX

"A very excellent test. Something should be done about improving the conditions, however (hi)."—W1BB.

"Suggest you give a multiplier of zero for all kW stations. With their excess power, that would certainly thin the results considerably."—AA1K.

"My first try at a contest. Hope I help those needing Rhode Island."—W1LOV.

"Excellent conditions the first night. Sure was a fantastic contest and I'm really looking forward to next year, now more than ever."—K1LPS.

"Lots of activity. The band was extremely crowded."—K1NBN.

"A very fine event! Many big signals, and there were more stations on the band than I have ever heard on 160 meters!"—K2DWI.

"Had nothing but antenna problems the 1st night. Blew a borrowed rig to top it off. I'll be back next year though."—AK2E.

"Excellent first-night European opening."—N4IN.

"Score would have been higher but had 300 kHz interference from an op who lives just down the road. He deliberately QRMs and the FCC has given him warnings about it."—W4PZV.

"My first 73 contest. Had a great time. Will have a better receiving setup next year."—W4TMR.

"The most enjoyable contest I've ever been in!"—W4TWW.

"A bunch of activity on the band. Hardly any DX."—WB4ZPF.

"Must say there was much activity and I certainly enjoyed it very much."—N5CG.

"Enjoyed the contest. Sounded like 20 meters. The strobe light atop my 300 vertical gave my receiver fits throughout the contest."—W5GFR.

"Thanks for a fine 160-meter contest."—AE5H.

"Nice contest. Ended up doing surgery and missed half of it, unfortunately."—K5JZN.

"Lots and lots of QRM!"—W5LFG.

"Very interesting contest. Sure enjoyed it."—KC5LK.

"Sure had lots of fun in the contest. Lots of QSOs and lots of QRM."—K6ANP.

"Great contest. Wish I could have worked the entire event."—WD6EFU.

"Enjoyed it, as I'm sure everybody did. Second night was not as good as the first. Doubled last year's score, though."—W6WBY.

"Had to work both nights but managed to slip in a few Nevada multipliers for the stations on the band."—W7ABX.

"Sounds like the contest is growing every year. Had a great time as did everyone I talked to."—KA7BTQ.

"Daytime contacts are okay but too bad you couldn't work a station a second time if you worked him the night before."—N7DF.

"Sure enjoyed the contest. Lots of stations heard on the band."—WB7FDQ.

"Super contest! I did better than last year and it sure helps toward my 6-band WAS award. See you again next year."—AK7H.

"Very enjoyable contest. Amazed at the number of stations on the band. All were very courteous. It was a real gentleman's contest."—K7SFN.

"Great contest. Heard a lot of activity from my QTH here in Montana. Plenty of QRM, too."—K7VIC.

"Daytime bonus points should be deleted."—KC8A.

"Had lots of fun and looking forward to 1983. The contest is definitely growing each year. Thank you, 73!"—N8AKY.

"S-9 power-line noise throughout the contest!"—W3CV.

Continued

"A fun, gentlemanly affair. Worked maybe 12 calls on 160 the last 35 years. This weekend I managed over 700 contacts!"—WD8CRY.
"Sounded like everyone had a great time."—K8HF.
"42 states worked. Not bad for a 25-foot helical-wound vertical with only 5 radials."—KC8NR.
"Enjoyed the contest very much. I think it is the best one held on 160!"—KC8P.
"Sure enjoyed the contest. Lots and lots of stations were on, I see."—AA8S.
"Daytime bonus was confusing. Had a great time, though."—K8US.
"The first 160-meter contest ever for me. I invited the Smoke Valley ARC over to help me out."—W0CEM.
"Unbelievable activity this year. 73 has done it again!"—WB0CMM.
"My first effort on 160-meter contesting. I was really impressed with the turnout. Had loads of fun."—KA0HIG.
"Sorry, no US stations heard on the band . . . just Europeans."—DF5ZD/A.
"Had a special 160-meter license and heard only Europeans."—EA3CCN.
"A very popular contest according to the turnout. Good luck."—KH6IJ.

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received at 73 Magazine by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial Offices, 73 Magazine, Pine Street, Peterborough NH 03458.

SOUTH BEND IN
JAN 2

A hamfest swap & shop will be held on Sunday, January 2, 1983, at Century Center, downtown on US 33 One Way North between the St. Joseph Bank building and the river, South Bend IN. Tables are $3.00 each in a carpeted, half-acre room. The Industrial History Museum is in the same building. Four-lane highways lead to the door from all directions. Talk-in on .52/.52, .99/.39, .93/.33, .78/.18, .69/.09, 145.43, and 145.29. For more information, contact Wayne Werts K9IXU, 1889 Riverside Drive, South Bend IN 46616, or phone (219)-233-5307.

WEST ALLIS WI
JAN 8

The West Allis Radio Amateur Club will hold its 11th annual Midwinter Swapfest on Saturday, January 8, 1983, beginning at 8:00 am, at the Waukesha County Exposition Center. Tickets are $2.00 in advance and $3.00 at the door. Tables are $2.00 in advance and $3.00 at the door. For advance reservations, send an SASE to WARAC, PO Box 1072, Milwaukee WI 53201.

OAK PARK MI
JAN 9

The Oak Park Amateur Radio Club will hold its annual Swap 'n Shop on Sunday, January 9, 1983, from 8:00 am to 3:00 pm, at Oak Park High School, southwest corner of Coolidge and Oak Park Boulevard, Oak Park MI. There will be ample parking and refreshments. Talk-in on 146.52. For prepaid table reservations, write OPARC, 14300 Oak Park Boulevard, Oak Park MI 48237.

RICHMOND VA
JAN 16

The Richmond Amateur Telecommunications Society will hold Richmond Frostfest '83, the annual winter ham radio and computer show, on Sunday, January 16, 1983, at the state fairgrounds, Richmond VA. General admission is $4.00. All flea-market and commercial exhibit spaces will be indoors in a 30,000-square-foot exhibit building.

SOUTHFIELD MI
JAN 30

The Southfield High School Amateur Radio Club will hold their 18th annual Swap & Shop on January 30, 1983, from 8:00 am to 3:00 pm, at Southfield High School, 24675 Lahser, Southfield MI. Doors will open at 6:00 am for exhibitors. Admission is $2.50. Reserved tables (payable in advance) are $18.00 for two 8-foot tables and $9.00 for each additional reserved table. Tables also will be available at the door. There will be food and parking. All profits go toward electronics scholarships and to support the activities of Southfield High School's amateur radio club. For more information or reservations, write Robert Younker, Southfield High School, 24675 Lahser, Southfield MI 48034, or phone (313)-354-7372 from 8:00 am to 10:30 am or (313)-354-8210 from 10:30 am to 3:00 pm Monday through Friday.

ARLINGTON HEIGHTS IL
FEB 6

The Wheaton Community Radio Amateurs will hold their hamfest on February 6, 1983, at Arlington Park Race Track Expo Center, Arlington Heights IL. Tickets are $3.00 at the entrance and $2.50 in advance. Doors will open at 8:00 am. Flea market tables are free and plenty of floor space will be available. There will be a large commercial area (including a computer section), awards, and clear, paved parking. Talk-in on 146.01/.61 and 146.94. For general information, call W9JTO at (312)-231-9524. For advance tickets, send an SASE to WCRA, PO Box QSL, Wheaton IL 60187.

MANSFIELD OH
FEB 13

The ARRL-approved Midwinter Hamfest/Auction will be held on Sunday, February 13, 1983, beginning at 8:00 am, at the Richland County Fairgrounds, Mansfield OH. Tickets are $2.00 in advance and $3.00 at the door. Tables are $5.00 in advance and $6.00 at the door. Half tables are available. Talk-in on 146.34/.94. For additional information or advance tickets, contact Harry Frietchen K8HF, 120 Homewood Road, Mansfield OH 44906, or phone (419)-529-2801 or (419)-524-1441.

MARLBOROUGH MA
FEB 20

The Algonquin Amateur Radio Club will hold its annual flea market on Sunday, February 20, 1983, at the Marlborough Jr. High School, Marlborough MA. Admission is $1.00 and children under 12 will be admitted free. The doors will open at 9:00 am for dealers and 10:00 am for buyers. Refreshments will be available. Tables reserved before February 12, 1983, are $7.00; any remaining tables will be $10.00 at the door. Talk-in on 146.01/.61 and 146.52. For table reservations or more information, contact Algonquin ARC, PO Box 258, Marlborough MA 01752.

GLASGOW KY
FEB 26

The Glasgow Swapfest will be held on Saturday, February 26, 1983, beginning at 8:00 am Central time, at the Glasgow Flea Market Building, 2 miles south of Glasgow just off highway 31E, Glasgow KY. Admission is $2.00 per person. There is no additional charge for exhibitors. The first table per exhibitor will be free, and extra tables will be available for $3.00 each. There will be a large heated building, free parking, free coffee, and a large flea market. Talk-in on 146.34/.94 or 147.63/.03. For further information, write Bernie Schwitzgebel WA4JZO, 121 Adairland Court, Glasgow KY 42141.

LETTERS

FIGHT CITY HALL

OK, Wayne, I've sat here every month and read how you think that the code requirement is hindering the growth of amateur radio. I think you are missing a problem facing amateur radio that is much bigger than a code requirement. The problem that I am referring to is local ordinances that restrict or prohibit amateur towers and antennas.

I can only imagine the number of hams who have worked hard to upgrade and feel that now is the time to put up that dreamed-of antenna system only to have their local government say it's illegal, so take it down. Why upgrade anymore? In fact, why even continue on with ham radio? It is truly disheartening to be told not to practice your hobby to its ultimate limit and enjoyment.

Believe me, fighting city hall is no fun (well, maybe a little fun when you win). I speak from experience. In my city, Cerritos, California, it took about 2 years of fighting city hall to get our ordinance changed. Led by George Goumas N6AWF, we outlasted our city officials by getting to meetings at 7:00 pm and often not being able even to begin our presentation as to why our ordinance should be changed until 1:00 or 2:00 am. Well, our perseverance paid off with a new ordinance that allowed us to go to 70 feet with a conditional use permit.

Wayne, if it had not been for many out-of-town hams who came and helped to fill up the council chambers, we would never have made it. Of the 100-plus hams in our city, only a handful were interested enough to come out for our hearings. It was the backing of the out-of-towners that saved our bottoms.

I applied for the first permit under the new ordinance. It was granted after a two-hour discussion with neighbors who claimed I was causing them continuous interference. A well-kept log book blew that argument away. I really thought that my permit was to end up on the scrap pile after a 137-signature petition against me was presented to the council. For a number of reasons that I won't go into, it had no effect.

From these experiences I have come to some conclusions that I would like to share with all amateurs. First of all, most of you don't care about what is going on around you until it hits you square in the face. Amateurs need to fight for their property rights as home owners. I have a little 50' × 100' piece of property that I'd like to call mine, but it is never mine when I have people telling me I can't practice a hobby that's not noisy or harmful. It's a lot easier to keep restrictive laws off the books than it is to change existing laws. Each amateur should make it his (or her) business to keep tabs on what is going on in his city. Finally, don't assume that because the guy a mile away has up a tower and antennas that there are no laws against it in your city. It may be that no one has complained to the city so they just haven't taken the time to tell the amateur to remove it.

Wayne, as much as I dislike fighting with my local government, I'll never stop fighting. It looks as if I will be moving in the next year so that I will probably have to go through the permit process again. Local governments are slowly taking away our personal freedoms. If you don't believe it, just check to see what kinds of no-nos are on your local government's books. These ordinances will range from what color you are allowed to paint *your* house to what you are allowed to park in *your* driveway. Believe me, restrictive antenna ordinances are becoming more of a widespread problem than you will ever know and are certainly more of a problem than a code test.

Carol Green KK6V
Cerritos CA

P.S. Since writing you this letter, our city is trying to pull the wool over our eyes again. They have decided to take the new ordinance and put it back into the Planning Commission for further study. So far through all of this, we have received no League backing. If the ARRL won't help us this time then I suspect that 100-plus amateurs in this city will no longer have any reason for belonging to the League because amateurs that cannot operate have no reason for belonging to an organization that deals with the operation of amateur radio stations.

HYPOCRISY

How far have we progressed in ham radio? Is it possible that our technology has passed our intelligence? Can it be that many of our population lean towards hypocrisy?

One of the most common comments one hears on the air is, "Ham radio is so great, it has something for everyone." I suppose they speak of the hobby where, if you have the money, you can own monobanders on each band, several transceivers, and amplifiers. Do we include the other guy? The one who lives by the dipole and no amplifier? Which hobbyist is more important?

Looking back, more than half of what I now have collected I owe to a list or a net of some kind. Myself, I have never taken a relayed report, which some seem so concerned about. The percentage of people who operate with the same self-dignity set of rules I operate with is probably 98 percent.

I have sat in awe at my station listening to what some say is the only way to work a DX station (the pileup). I have heard gentlemen such as FB8WG and A51PN (and the list could go on) try to dig a call or just a letter out of the pileup; being unable to do so because people kept calling so long, they just go QRT or QSY.

Gentlemen, channel efforts towards making ham radio a better hobby. During contests, for example, stations all over the bands run 20-30 kHz wide. These guys don't care, because it keeps others from moving close. Why not focus support towards allotting overlapped segments of the General and Advanced band, i.e., 14250-14300 kHz. This way, non-contesters are not forced out of their weekend of operating. How many lists or nets mess up the whole band for others throughout the entire weekend? I suppose that's OK, though, because somewhere, someone up there likes contests.

I firmly believe that the majority of the old-timers that are against lists or such have all or nearly all of their countries and have done so during times when the ham population was one-tenth what it is today. I would like to see them start over with a dipole and barefoot.

I hope any kind of stand against lists and/or nets is only a rumor. Let us consider how much control any organization which is supposed to help hams should have over how we make a contact.

I feel the desire for the coveted accomplishment in each of us will stop the taking of the invalid report. Those who are dishonest will find a way to be dishonest in every facet of ham radio, no matter what rules are set.

Gentlemen, ponder this and let's all try to improve what we have and not take away that which each of us is entitled to.

VENDOR SERVICES

You know the cliche: Each of us is eager and ready to take pen in hand and complain, grumble, bellyache, etc., against or about some vendor or products or services. But to say something nice about someone or something, that is another scenario, and here comes one.

I have been a ham for about four years, starting at the tender age of 57. In this relatively brief period I have sampled the wares and services of many vendors selling to amateur radio people. Overall, it has been a pleasant experience, but let me single (or is it double) out two vendors from the many I have experienced.

First—Trio Kenwood, makers of fine rigs for two-meter and HF operation along with excellent, if somewhat expensive, audio gear. I have been particularly impressed with service out of their Compton, California, site. They are professional and timely, either by mail or through the reception desk. One gets to speak to a technician right up front, and if the one serving you is not familiar with your particular rig he goes for help in the back room. The rule is courtesy and the proper amount of sympathy. When appropriate, charges are less than the "minimum" posted in the reception area. Service time is often less than posted minimum time. All in all, *real* service after the sale!

I am equally happy with the products and service from Communications Specialists, Orange, California, makers of tone generators for PL applications. Customer service by telephone has always been polite and efficient. You get the feeling that they care about their customers. On several occasions, they have given no-charge service well after the end of the warranty period, sevice required by my clumsiness rather than product failure. Again, a company that unstintingly backs up its product.

I would like to hear from other hams with similar experiences.

I. Olitzky KA6CLE
Venice CA

BE AN ELMER

For the past several months I have been reading letters directed to you by proponents and opponents of code-free licensing. I have yet to read one letter that addresses the central issue, which I believe is how we as amateurs propose to make our hobby better.

I struggled with the code and theory as, probably, most do . . . my callsign attests to that. The pivotal feature is that perseverance and desire can get most everyone past the hurdles. I do not feel that 20-wpm code . . . 13-wpm code . . . nay, even 5-wpm code, nor Mr. Bash's crib text detract from amateur radio; neither do I feel that those things support ham radio. I feel amateur radio's biggest asset lies in the individual hams who comprise our society and the fact that ham radio is a challenging and just plain fun hobby.

Each and every one of us, the already-licensed hams, should do our part to fascinate, encourage, instruct, and support non-hams in the acquisition of an amateur license. We should, on an individual basis, be Elmers to any who show an interest. We should, as groups or clubs, promote and participate in spreading the word that ham radio is fun by supporting and teaching classes. Learning aids are available. *73*, Heathkit®, the ARRL, Ameco, and others publish many fine learning aids. The FCC, while not always as responsive as we would like, is the arbiter of our licensing exams and makes those exams available on schedule and without prejudice.

What may be missing is the incentive for us as individual hams or groups of hams to encourage others. I propose that *73* spearhead an effort to encourage hams to teach others about ham radio. How?

1) Awards: I propose that *73* offer awards to individuals and clubs, similar to operating awards, for getting amateurs licensed.

2) Instructor training: Most of us can learn but many require help in the form of syllabi, group instructional aids, and teaching techniques to enable us to help others. Publish these aids.

3) Public knowledge: Advertise to make the public aware of amateur radio. The ARRL does this to some extent—more is needed.

4) Hotline: Match Elmers (either individuals or clubs) with prospective amateurs needing help. Might work like an computer dating service. A national 800 number hotline is one possibility.

5) Service awards: Encourage clubs to promote themselves by offering club awards for participation in activities like SETs, RACES, MARS, etc.

These are some of the possibilities. There are probably many more ideas which would work better or attack a different front. Not everyone wants to become a radio amateur. For one thing it requires some discipline and effort and not everyone is willing to devote the necessary energy. I feel that everyone who is willing to make the necessary commitments should be given all the help possible by all of us amateur radio operators everywhere.

BASH REFORM

I am a 15-year-old at Hereford High, and I am writing about the public outcry (what little there is of it) towards Bash Educational Services. In *73* for November, you reported the failure of 89 percent of one of Bash's classes and restated your opposition to the books and classes. I must admit that I have great respect for anyone who takes a firm stand for their own opinions. However, I do disagree with you on the "Bash Book" debacle.

When you really think about it, Bash's system was a radical concept, but as with all once-new ideas, an improvement is needed (not a ban).

Now think about this: You have to admit that for anyone intent on passing "Big Brother's" exam for upgrade it is a Herculean effort to find all of the information (much less, carry the ton of books needed) for passing the bewitching exam; even the *ARRL Study Guide* is nowhere near enough. Anyone who has no prior knowledge of the theory will quickly find out that the *Study Guide* is a good book for introducing them to the theory but in no way prepares them for the double- and triple-talk used by the FCC to befuddle our minds. If you get all of

the necessary books to study out of, you wind up studying a lot of information, 70 percent of which you will probably never use or want to know or is not even on the test. All of this useless information mainly serves its purpose by wandering around our minds and mingling with the facts needed. This usually causes a nasty surprise in the form of a failure.

My idea for improvement is a simple change. Continue collecting Qs and As from tests but not for printing in cheat books. I would simply use these and take all of the ham-radio-related books I could get (if I had the sources) and find all I could in the way of theory and facts to back up all of the answers. Take these arranged facts and write them into an easy-to-understand form of writing with flavor and a small vocabulary (*you want more young hams; write it so we can understand you*). Without using boring, dragging wording, present the theory well, and towards the end of the book introduce readers to the language used by the FCC and get them very familiar with it. Also, a copy of the regs in FCC form with simple English definitions would be desired by many people.

I think that anyone bringing out such a book would end the era of the Bash Books. I know that my idea is not new, but I have yet to see it in the print of a large magazine.

Thank you for your good magazine and for your time.

Glen White NA5Z
Hereford TX

YOU'RE MY TYPE

Your last two issues of *73*, namely October and November, have been more my type of magazine. Since I keep my own notebook of the interesting articles I see in the mags, you have kept me busy lately. You see, I look for articles that look interesting to put on the breadboard and play with and when I've played with one long enough and it looks like a good project to finish, so much the better.

In regard to your continually pressing for more amateurs, I feel that I must put in my two bits' worth. Of all the 50 or more Novices that have passed their exams around here the past two years or so, there are only about two or so on the air. Everyone is interested in DX—how far can we get out, etc. The biggest problem seems to be money. Very few seem to be interested in building. *Frankly, I think we need a good set of* textbooks that will take the prospective ham from beginning to end.

I'm all for your computer networks, but so far your computer articles are way over my head and I cannot afford the price of a computer to figure them out. The day you can show me *73* articles where I can borrow my wife's portable TV set and, with the minimum of cost, put it on the air, that will be the day. You'll have to hurry, though: I'm 74 years old.

SCHOLARSHIPS

The officers and directors of the ARRL Foundation announce the recipients of two awards for the 1982-83 academic year. The Long Island School Scholarship, for youths attending Long Island colleges or universities, has been granted to Paul Michael Silverman KA2DSP, of Levittown NY. He entered State University of New York at Farmingdale in September to pursue courses in electronics technology. The $250 ARRL Foundation-administered award was given to this young man for demonstrated interest and excellence in promoting amateur radio and for aspiring to an electronics carreer.

The YL ISSB Memorial Scholarship has been awarded, for the second successive year, to Larry Edwin Smith, Jr. WB9UKE. The awarding of $709 to Larry concludes the ARRL Foundation's administration of this scholarship fund for YL ISSB. Larry pursues associate and bachelor's degrees in electronics engineering, aspires to a career with NASA communications, holds amateur Extra and 2nd class commercial licenses, has maintained an A academic average, and has been very active in extracurricular activities at Vincennes University.

ARRL *Foundation-administered scholarships* are open to all applicants, qualifications and specific criteria being reviewed by screening boards consisting of ARRL Foundation officers and directors and panels provided by sponsoring organizations. Application closing date is May 1, 1983, for the next academic year.

Secretary, ARRL Foundation
Newington CT

FINDING BIRDS

Finally, I have found why the RS-n satellites aren't where they were supposed to be: The tracking program was wrong! I'm referring to "Tracker—The Ultimate OSCAR Finder," p. 88, *73 Magazine*, January, 1981. The computation for satellite longitude is correct only for satellites with inclination greater than 90 degrees. The sign of the variable SO needs to be changed for satellites like the recent Russian ones with inclination less than 90 degrees. I take care of it in my revised Apple version this way:

```
2010 CA = COS(IN):SO = - SO*CA/
     (ABS (CA)) + CO*RD + RD*TI/4
```

There are *many* ways to accomplish this sign change; this is the mathematician's way.

Actually, this program is not the only place this error is made. The RSGB *VHF Handbook* puts that correction for inclination on the TI/4 term. The reference that I found to explain this correction is by Bryan Leipper, "Circulation Orbits with Simple Computing Systems," *QST*, February, 1979, pp. 38-42.

Dr. Gerald N. Johnson KØCQ
Ames IA

Thanks for the tip, Gerald. We thought the Russians were just being obstinate.—Eds.

NO FAULT, PCBs

I just finished reading "Avoiding the Electrical Nightmare," on page 64 of the October issue regarding the unusual voltages encountered by N4UH of Cleveland, North Carolina. I was prompted to write because, while his technical analysis is correct, his terminology is not. There is a great difference between a "ground fault" and the condition he describes which is an "open neutral."

A true ground-fault condition is just what the name implies—a fault to ground, or earth. Visualize your electrical panel and the wires in it for a moment. The black wire from the breaker is *the neutral or return part* of the circuit. An electric light connected between the black and white conductors completes the circuit. The current flowing "out" the black wire is equal in magnitude to the current flowing "in" the white wire. If we introduce a fault into the circuit (such as a broken insulation protecting the black wire from shorting to the panelboard box), then current will flow through the light fixture and back out as before, but also through the black wire to the insulation fault to ground and back to the neutral at the point where the neutral and ground are common. This is a ground fault and the current flowing in the ground conductor is not equal to the current flowing in the neutral return.

Ground-fault circuit interrupters (GFI or GFCI) are devices that sense the current flowing out the black wire and the current flowing in the white wire. If the difference is *greater than 5 mA (for the typical residential units)*, then the device interrupts the current. If the fault from the black wire to ground was through your arm, you would be most appreciative.

The fault described in the article is an entirely different problem. The problem experienced by N4UH was an open neutral. The return conductor (the white wire) was open, creating a voltage-divider effect between the legs of the power system.

The National Electrical Code (NFPA-70-1981) requires that all electrical systems be grounded. The grounding should be accomplished at a single location. This location, as required by the code, is at the supply side of the service at the main service disconnect. This is the only location where the neutral and ground are brought together. All of the uninsulated ground wires running around in your Romex are for the purpose of extending this ground point to each and every receptable and light fixture in your house. A ground fault at any location in your home will cause the ground conductor to carry the return current back to the common point with the neutral at the service disconnect.

It should be noted that the type of problem encountered is rare and should not cause alarm on the part of those with aluminum service-entrance conductors. Utility practices vary but always account for the problems of aluminum oxidation. Aluminum connections, if properly made, are very reliable and need not be of concern to the homeowner. (This applies to the larger sizes of aluminum and not necessarily to aluminum branch-circuit wiring, but that would be the subject of an entire article in itself.)

As long as I am writing, I also would like to extend a word of caution regarding the *article on page 29, "Dissertation Upon* Roast Pig," by N6TO. The transformers obtained from the utility most likely were immersed in mineral oil. A few transformers are still in circulation, however, which contain polychlorinated biphenyl (PCB). PCB is a major component in coolant known as "Askarel." This is nasty stuff which is very toxic and must be disposed of in accordance with EPA regulations. Under no circumstances should you attempt to use a transformer that contained this coolant. The utility should not even consider selling you a transformer which contains PCB. Because the utility may not know which transformers contain PCB, you may discover one by mistake. In addition to transformers, some high-voltage capacitors used in commercial equipment a few years back also contained PCB insulating material. Be cautious with all surplus and used electrical components containing oil for cooling or insulation.

AMERICAN & METRIC
62-PIECE
HEAVY DUTY
INDUSTRIAL TOOL CHEST

$28

Before Midnight Jan. 23

We will send to each reader of this publication who reads and responds to this test before midnight Jan. 23, a 62-piece American and Metric Heavy Duty Industrial tool set and metal storage chest containing all the basic and special tools necessary to service and repair domestic and foreign trucks, tractors, autos, and all heavy industrial machinery. Consists of 7 American 3/8 inch drive sockets (3/8"), (7/16"), (1/2"), (9/16"), (5/8"), (11/16"), (3/4"), 9 American 1/4 inch drive sockets (3/18"), (7/32"), (1/4"), (9/32"), (5/16"), (11/32"), (3/8"), (7/16"), (1/2"), 9 Metric 3/8 inch drive sockets, (9MM), (10MM), (11MM), (12MM), (13MM), (14MM), (16MM), (17MM), (19MM), 9 Metric 1/4 inch drive sockets, (4.5MM), (5MM), (6MM), (7MM), (8MM), (9MM), (10MM), (11MM), (12MM). A 3/8 inch fine tooth ratchet with quick release drive combination-forward and reversible, a 1/4 inch × 3/8 inch adapter, a 3/8 inch drive extension bar 3 inch. A 3/8 inch spark plug socket with oil resistant insert and speed installation and removal. An 18-piece industrial steel ignition wrench set, complete set of spark plug gap setting gauges for any type of spark plug. One "1/4-drive heavy screwdriver. (One) large set of feeler gauges, industrial "Phillips" heavy duty and "regular" screwdriver. All tools are drop forged alloy steel for durable heavy duty repair work, and will be accompanied with a LIFETIME guarantee that it must perform 100% or it will be replaced free. Add $7 handling and crating for each Tool Chest requested, we pay all shipping. Should you wish to return your tools, you may do so for a full refund. Any letter postmarked later than Jan. 23 will be returned. LIMIT: Six (6) sets per address, no exceptions. Send appropriate sum together with your name and address to: Tool Test Dept. #120DW, *Viking Ind.*, 6314 Santa Monica Blvd, Los Angeles, CA 90038, or for fastest service from any part of the country, call collect before midnight 7 days a week (213) 462-1914 (Ask for) *TOOL TEST*, #120DW, have credit card ready.

W2NSD/1
NEVER SAY DIE
editorial by Wayne Green

from page 8

bringing world reports to *73* could do the job.

We do have a world hobby, so let's see if we can get it together more.

HAMMING FOR CREDIT?

Down in Georgia there is a proposal to have ham classes count for educational credits. That's a good move.

There is a desperate need to get amateur radio going again in our schools and this approach could generate some interest for the students. It would be a way of, so to say, paying the students back with credits as well as in fun.

Though it is old hat to *73* readers to read about the needs America has for technical people, . . I've been writing about that for several years now . . . I see that the general media are getting more concerned over the problem. Even the normally liberal writers are getting to worry about the overwhelming loss of technical consumer products to Japan.

With the increasingly rapid development of video technology, microcomputers, data access over the phone or via television stations, video teleconferencing, satellite services, 100-channel TV cables, and so on, it is getting ever more difficult for the general public to ignore the coming developments. They've even been noticing that almost all of the recent developments have been coming from Japan and figured out that this just might make it difficult for America to catch up once we fall seriously behind.

Articles about this have been appearing with increasing regularity in *Newsweek*, *Time*, *Business Week*, *Fortune*, and so on. The situation is getting so serious that a small handful of our educators is beginning to get uneasy. When a problem reaches that level, you know it has to be serious.

Naturally, there are pressures for our government to force Americans to buy more expensive and technically-inferior products just because they are made here instead of in Asia . . . just as there are heavy pressures to force Americans to buy crummier cars because they are made here. I'd like to see more interest in American productivity, American pride in perfection, and American unions promoting something besides the highest pay possible . . . with the result that the products are priced out of the market.

But that's another problem . . . to some degree. The key to any American success in communications and computers in the next twenty years lies in our having the technically-qualified people to invent the products, manufacture them, sell them, operate them, and service them. This is going to take an enormous number of engineers, technicians, and scientists . . . vastly beyond anything which we even have in prospect to develop in this country.

Only Japan has laid the groundwork to develop the high-technology people who are going to be needed to provide the whole world with video, computers, information, and other technical services which are going to be the key to personal happiness, business success, and educational achievement in, say, twenty years.

While we're busy lowering our academic standards and seeing our proponents of liberal-arts education winning most of the battles in academia, we see Japan loading their schools with enthusiastic technically-inclined students. Do you realize that there are over 900,000 amateur radio operators in Japan today? They have us outnumbered in active hams by a margin of at least three to one . . . possibly four to one . . . and Japan has only half of our population! They are running rings around us.

Amateur radio has never been a very popular hobby in America. Even when we were growing at our greatest rate, back in the 1950s, we were growing at only about 11% per year, which was about 22,000 newcomers. Then, with the "incentive licensing" disaster of the 1960s, we fell to zero growth (and worse). Now we're back into a growth mode, but not an impressive one.

Unless the Japanese technology program runs out of steam, their teenagers will be doubling the number of hams in Japan in the next three years, while at our rate of growth we are looking at about eight years for a doubling of our hams.

There has been some criticism of calls for more engineers with a reminder that only a few years ago massive numbers of engineers were dumped and were unable to find work. To a degree, that is right. But what is glossed over in that response is that the engineers and technicians who joined the unemployed were those who had not kept up with the changes in technology. There has never been any surplus of technically-trained people.

Remember that by 1970 it had dawned on even the most backward of firms that solid state was here and unavoidable. This was when the axe fell. Those engineers who were living in the good old tube days were suddenly not needed. This axe was wielded again when the industry discovered ICs and had no further use for engineers who could not cope with them. Each new generation of electronics is going to be ruthless in weeding out the people who do not adapt.

Today, the need is for young engineers and technicians. Our schools have been almost totally emptied of these talented people, leaving the over-40 remnants of previous technologies to try to teach things they haven't bothered to fully understand. This does not bode well for our schools or the next generation of kids . . . the ones we're depending on to cope with the Japanese incursions.

Amateur radio can help, at least to a degree. By interesting teenagers in a high-tech hobby, we may be able to develop the engineers and technicians we need, both for industry and for our schools as teachers. Of course, the exceedingly slow growth of amateur radio over the last twenty years has meant that the average age of amateurs has been rising steadily, with the result that within our ranks we have few qualified teachers to get new hams started. The technical competence of hams as compared with industry has been dropping for twenty years, where at one time hams were a cut above the average engineer or technician.

I can remember the time when hams were responsible for virtually every major breakthrough in radio communications. Now we can merely point out that long ago hams pioneered FM, NBFM, SSB, SSTV, RTTY, and so on. We old, doddering relics of the past can remember the pride of those olden days. But the world is ruthless; it wants to know what you've done for it lately. Not much.

The plan for giving scholastic credits for ham classes is a fine move; let's see if we can get that idea spread around. I'll be interested in getting articles for *73* on proven ways of getting teenagers interested in amateur radio and on successful programs to get amateur radio growing.

In the meanwhile, I'd like to see a lot more articles in *73* on current technologies. Perhaps we can get amateur radio back into developing some inventors and pioneers of new techniques. Running articles on designing and building kilowatt tube-powered linear amplifiers is not it . . . unless someone designs a digital automatic-tuning device.

There is no shortage of things to invent which are well within our technical capability . . . if we let ourselves go and get cracking on it. For instance, we could use a system for automatic identification of transmitters so that our receivers would indicate the call of the station being tuned in as we tune. This could be done via an ASCII signal sent on a subcarrier, thus furnishing the receiver a reference signal to use for automatic tuning. Once we have that development, we will be ready for receiver-tuning systems which will be automatic, alerting you when chosen prefixes or calls are tuned in.

This could be a great stride ahead for amateur radio, pioneering a new digital communications technology which could be quickly applied to CB, two-way, and most other communications services. It could help to bring about some extensive changes in amateur radio operation, too . . . perhaps the first real changes in over 50 years. Except for the development of

the vfo, our Morse-code communications has changed hardly at all in 50 years. And other than the shift to SSB, phone communications is almost identical to hamming of 50 years ago, complete with pileups on DX, jamming, endless nets, and so on.

We've had practical RTTY on the ham bands for over thirty years and there still is no noticeable dent in traffic handling as a result. Amateur radio, which at one time was the spawning ground for new technologies, has turned into the most rigid and unchangeable remnant of the past.

You invent it and we'll publish it. . . okay? Let's get amateur radio into gear for the first time in years. The last change of any sort was over ten years ago when we went to FM and repeaters on two meters. Unfortunately we contributed little technically in this move, merely taking advantage of the already-existing technology developed for two-way commercial operating. Now let's do some pioneering for a change.

DIGITAL MANIA

With the new freedoms being granted by the FCC, I'd like to see some serious experimenting on our bands with digital techniques. Ham radio is never going to go anywhere unless we get busy and take advantage of the recent technological advantages in ICs.

For one thing, isn't it about time that the RTTY crowd stopped puttering around, dodging QRM, and came up with some circuits which will dig out those weak signals and copy them? I tried a recently-advertised computerized-RTTY setup and was astounded to find out how crummy it was. . . even as compared with the circuits we were building back in 1948. Almost any kind of interference sent it into spasms of incomprehension.

Fellows, I have some news for you. You should be designing RTTY gear which uses the el cheapo computers such as the Timex 1000 (Sinclair ZX81), the Atari 400, the VIC-20 and so on. Your circuit should make it duck soup to tune in a signal. . . and copy should be 100%, despite CW or other neighboring RTTY signals. You should copy through QRM, QRN, jamming, fading, with any shift, and so on. Let's get cracking at this and stop horsing around with junk which falls apart as soon as a vindictive CW-monger gets on channel. There is, as you may not know, apparently an unlimited supply of CW jammers, all with unlimited time to sit and trash RTTYers. Perhaps we should devise a certificate, with yearly awards.

And while one contingent is doing the inventing which should have been done several years ago but which was prevented by the FCC, bless 'em, others of you should grab your chips and start working seriously on automatic identification for transmitters. Some early experiments indicated that a system would work using a frequency-shifted subaudible tone, but we need to do a lot more work on this. If someone can come up with a relatively simple system which can be built into every transmitter, we can save the several eons of time every year which are presently wasted with redundant identification. Just think of the saving on pileups alone, where perhaps around five thousand stations are giving their calls from fifty to one hundred times per minute, hour after hour. There is a zero in Minnesota with the unofficial record of 117 complete identifications in one minute! A record to be envied. I understand there is a move to get this amazing chap on "People Are Weird."

Once we have a fairly fast automatic-identification system, we'll be able to instantly read out the call of any station tuned in on our receiver. We'll also be able to build in a microprocessor to check the call for wanted calls or prefixes. Those rare ones can come and go pretty fast sometimes, so why miss one just because he is 50 kHz down the band from where you are working? With an automatic tuning system (dual tuning, of course), one receiver tuner will be on your channel for you while the other is scanning the band, checking out the prefixes.

And a couple of years later, the whole thing will be in an HT for us. Just ask any of the early two-meter folk about the first FM rigs and compare them with the programmable, scanning-all-channel HTs of today. You know what we haven't seen yet? Anything!

So, while all you old-timers sit around and fondle your 807s, we're looking to the youngsters to stop fooling around with girls, get going with with their pile of ICs, and invent us out of the 1930s morass that amateur radio is in today. The technology is here. The parts are here. The need is here. . . and riches are awaiting the entrepreneurs who make it happen.

One thing is for sure. . . if you invent it, I'm anxious to publish your articles in *73* and get the ball rolling.

HELP!

Every now and then I see a notice that the League is looking for some hams to add to their staff. Fine, I suppose, though my understanding is that the place is very, very structured. It also isn't growing much, in case you haven't read their yearly report. When I say it isn't growing much, I mean that the League has been losing members at an increasing rate for the last few years. That would make me nervous.

Now, while they've been shrinking away, my little empire has been growing steadily. They need people to replace those who have bailed out. I need people to help us grow even more. . . and I don't think anyone would really characterize this place as rigidly structured.

In addition to needing a good all-around ham or two to test ham gear and write reviews, to keep the W2NSD/1 hamshack state-of-the-art in RTTY, slow scan, repeaters, antennas, and so on, we also need someone to keep our microcomputers running. We have a hundred or more around here and the darned things keep breaking. I think we could keep a compulsive technician exceedingly happy.

Our audio department has a serious need for a technician to be on top of all the digital recording techniques and assure us that our digital and audio cassettes are first-rate.

For people who for twisted psychological reasons are not particularly interested in living in the finest area of the whole country (the world?), we do have some part-time jobs available which can be done from anywhere. These call for a good deal of responsibility, of course. We're building our national network of sales people and have several nice areas still open. This would entail getting out to visit computer and electronics stores about three days a week to make sure that they are well stocked with our magazines, books, and computer programs.

In Peterborough, we have open positions for people with PR and advertising experience, sales, editing, writing, graphic arts, photography, and so on. In the next year, we expect to add at least 100 people to the staff. . . possibly 200, if we can find them.

We're looking for non-smokers who are more interested in developing careers than in just landing a job. We'll be able to keep up our growth only if we keep up our enthusiasm and innovation. Indeed, we've been growing briskly for seven years now, and by the end of this month, we expect to be about five times the size of the ARRL.

So, if you are not a smoker and you're looking for a place to put your outstanding talents to work where they can do the most good. . . and where you will be able to learn more and grow, think in terms of Peterborough. Send along a letter detailing why we can't go a step further without you. . . and a resume.

COMPUTERIZING

With over 40% of the *73* readers computerized. . . and with thousands more eyeing the Timex computer. . . I'd like to make sure there is no misunderstanding. I want to see you experimenting with amateur radio applications of these contraptions and writing up your results for *73*. The readers are interested in articles on getting rid of computer noise. . . in protecting the computers from interference from the rig. . . in RTTY applications. . . high-speed code. . . beam aiming. . . log keeping. . . automatic QSLing. . . packet communications. . . and so on.

Unless you write up the results of your work, it will be wasted. . . giving only you the benefit. The more you write about what you are doing, the more hams will join you in experimenting and developing new ideas—and we'll all benefit.

Remember, too, that the market is just starting to open up for add-ons for the low-end computer systems. There are millions to be made by those who come up with practical new ideas. We've already seen dozens of new millionaires as a result of the recent microcomputer developments. . . and we haven't seen anything yet. With

hundreds of thousands of Timex computers being sold, just about any useful accessory for it will be able to generate millions in sales.

In order to encourage this development, *Microcomputing* will be devoting a special section to the low-end computers. We need not only interfaces, programs on cassettes, and so forth, but we may also have a need for better ROM character generators and operating systems, plug-in ROM programs, and so on.

I've helped a lot of people get very wealthy in the microcomputer business... and I can help you, if you are seriously interested. I write about this in my editorials in *Microcomputing, 80 Micro,* and *Selling Micros*, and I'll be covering this aspect in *inCider*, too. It's fun to be rich, and the opportunities are almost unending. As a ham, you have an inside track, if you have the will.

HOW'S THE ARRL DOING?

Too bad you didn't get the *QST* annual report... and read it. In amongst the lavish self-praise... an orgy of it... are the stark financial figures, and they are so dark-cloud that they tend to cut through the baloney. Membership is down. And despite the massive increase in the subscription price for *QST*, the income for the League has not even kept up with inflation. Nowhere near it!

The financial management in any normal business would call for the immediate replacement of the people responsible. Of the 74 stocks and bonds in which the League has put the money they've made in profits in past years... being a nonprofit corporation they have to salt away all that money rather than distribute it to the stockholders... only eight are worth more now than they paid for them. Maybe you were wondering who was investing in oil companies, railroads, and so on. Heh, heh... *you* are.

They seem to have concentrated on economizing on membership benefits such as awards, cutting that by 76% in 1981. This is balanced by an increase in unemployment compensation which went up by 973%... yep, almost ten times, as staffers went through the old revolving door. That's quite a one-year record.

Automobile expenses only went up 370% in the year. Are they providing limousines for the top echelon these days? We did see healthy cuts in such pork-barrel items as ARRL headquarters expenses, which were 70% higher in 1978. And the W1AW expenses came down, too. They were 51% higher in 1980. It looks as if someone made a trip somewhere, because while there were no overseas expenses chalked up in 1980, they managed to spend $17,762 in 1981. That's a very nice trip!

Unless you take a serious interest in League financial matters, you have no beef about what they are doing. You are a stockholder of the corporation and should look into how your money is invested. You might even question why the HQ people are salting away millions in stocks and bonds, losing your shirt for you with poor investments, when perhaps they should be spending your money on more services... or, even better, in encouraging some growth in amateur radio.

A million-dollar budget to produce some first-rate films about the excitement of amateur radio... about the benefits of amateur radio to our country... about how to start a high-school ham club... could get amateur radio growing again. We have plenty of friends in television broadcasting to see that the films would get on the air. And a million dollars wouldn't even put a big dent in the bankroll they've built up. It might keep them from blowing so much on lousy investments ... and, after all, isn't that what the money *should* be used for?

Look, I know you hate to have me carping about the League... but I'm not giving the League hell right now. I'm giving *you*, the League member, hell. The chaps at HQ will do whatever they want with your money if you don't say anything. It's only by your being a silent partner to the crime that all this money has just plain been thrown away. You haven't been paying attention. You haven't been insisting on meeting with your directors and finding out from them what the situation at HQ is... and they are not going to level with you unless you push them. They'll put the pressure on for membership benefits... and for promotion of the hobby... but only if you lean on them.

The League, under the direction of the directors you have elected, has been spending a pittance on membership benefits and promotion of the growth of the hobby. Get after 'em... let's see some growth.

MAJOR LEAGUE CHANGES AFOOT?

Knowing how undependable the rumor mills are, I don't put a lot of stock in repeated reports that Skip Tenney will soon be promoted as a replacement for Vic Clark as president. Tenney, well known as the publisher of *Ham Radio* magazine, either has sold or seems about to sell what is left of his magazine, so that would make him both available and eligible for the spot.

The move makes sense, too, when you consider how close Tenney has worked with the League all these years. At times, it has seemed as if he were almost an untitled League official. Being independently wealthy, Tenney wouldn't be restricted by the lack of remuneration which goes with the position.

A lack of expected aggressiveness on the part of the recently-appointed president seems to have sparked the search for someone to help take hold of the organization and get it into shape. Many of the directors feel that it is important to have a businessman with experience helping to guide the League into safer financial waters... and perhaps stem the growing loss of *QST* subscribers.

Others of the directors like Vic and feel that he should have more of a chance to get things turned around... to, so to speak, haul the old boat out of the water and scrape off the barnacles. I've personally always held Vic in the highest regard as a ham and a DXer. The directors should realize that even with a relatively small organization such as they have at HQ, people get set in their ways and it is difficult... often very difficult... to bring about changes, no matter how badly they are needed. My unasked-for council would be to give Vic more time and not rush with Tenney.

BUILDERS VS. BUYERS?

Sometimes I get the impression that people will believe just about *anything*! First, we had a bunch of old hams, probably irritated because they had to change from AM to SSB, grousing that hams weren't building any more. I still hear that chorus when I visit some ham clubs, many of which seem to have been taken over by old old-timers.

When I point out that there are more ads for parts in *73* these days percentage-wise than there were in *QST* forty years ago, they look shifty-eyed and shut up... at least until I'm safely out of earshot. The fact is clear that hams are building as much or more than they ever did. It just isn't the old ones who are doing it. Possibly they're too busy watching television.

The increased coverage of relatively simple building projects in *73* has sparked a lot more interest in building and experimenting. Fine... for that's one of the great pleasures of electronics and hamming. I put quite a few years in at the workbench myself, with a barn full of old gear I built to show for it... and a twisted pelvis from standing on one foot for about twenty years. The local chiropractor has given up trying to straighten it... and I've stopped seriously trying to lift anything heavy. I've paid my dues in building.

There is a gross misunderstanding on the part of some of the manufacturers in the industry. This is odd, because it really means that they have been reacting emotionally and not giving any serious thought with some research.

This has to do with the interesting concept that hams who build are not very good customers for commercial equipment. The facts are the opposite, as even a few moments of contemplation will make clear. The major buyers of new equipment are the exact same people who are also building gadgets. How come? Let's look at it.

First, a little lesson in economics. Way, way back, in the early days of amateur radio, hams built their own receivers and transmitters. There were only a handful of hams then, so there wasn't enough of a market to warrant commercial equipment for them. Then, when the first commercial receiver was put on the market, the home construction of receivers virtually stopped. Hams quickly realized that a home-built project would cost more, have a smaller resale value, and not work as well as a commercial receiver. They did just what you and I

would do in the circumstances: They bought their receivers.

I came along just shortly after these halcyon days, getting started as a shortwave listener along about 1936 and doing my first pirate operating (called bootlegging then) in 1938. There were no practical transmitters for hams as of that time, there being only about 40,000 licenses. These came along after WWII, when our ranks had swelled to about 80,000. But we did have some beautiful receivers and the hams ate them up.

As a teenager, I was living in Brooklyn and I made it my business to visit as many of the active hams as I could. In those days virtually every licensed ham was active. I visited well over a hundred hams and found just one who had built his own receiver. It really wasn't practical from any viewpoint.

Once transmitters got practical, hams stopped building transmitters. . . with a few exceptions. We've always had a few stranger-than-normal hams, but not many. I went the same route myself, buying war-surplus rigs and converting them. I did build power amplifiers. . . but only because they weren't commercially available.

Much of my own building was involved with complex RTTY gear, autocall circuits so that my RTTY could work automatically, and so on. Those of us building this sort of stuff were getting into digital electronics. . . back in the late 40s. . . 35 years ago!

But then, as now, we bought our rigs and receivers. Further, then, as now, when we bought our commercial equipment we went for the best and the newest we could get. This was only natural since we were deeply involved with hamming and wanted to get the best out of the hobby. Why would I go to the trouble of spending two weeks designing and building a piece of Teletype® equipment and then hook it to a crummy receiver? No way! I went for the best and so did the rest of the builders. They're still doing this.

Today hams *are* building gadgets and enjoying it. But you can bet that these active hams are also very particular about the commercial gear they buy. You can also bet that they are lying in wait for anything new that comes along. These chaps are the best of customers for the industry because they are the most deeply involved.

It is the older hams who already have their KWM-2s who sit and rag-chew, who talk endlessly on nets, who are the bane of the industry, not the enthusiastic builders and experimenters. We are fortunate in that we do have a magazine in the ham field devoted to these nice old men, complete with pages and pages of "operating news" for them to read each month.

When you consider what an incredible bargain ham gear is today, I get a bit aggravated when I hear someone griping about the high cost of it. Lordy! When I got started in hamming we had crystal-controlled transmitters and each crystal cost about \$3.50. Not bad—until you translate that into 1983 dollarettes, which puts those nice little crystals at about \$63 each.

The cheapest hunk-of-junk ham receiver on the market, the Hallicrafters Sky Buddy, cost \$19.50. Cheap? Well, my friend, if we look at the comparable prices for other things, that comes to about \$350 today. The average ham wanted something better, running around \$80, or about \$1,500 in today's puny money.

No, we're getting incredible bargains today as a result of the solid-state revolution, ICs, and mass production. Japan, with nearly one million licensed hams, has such a huge market for new ham gear that the production quantities have brought down the cost of manufacture to much less than one half what it would be without them. Each doubling of production normally drops the cost of manufacture about 15% or so.

So, though we hams are building more than ever before, we also are buying as much as we can get commercially made. . . and getting incredible value for our investment.

ARE YOU MISSING THE DX?

Now, I suppose I should shut my typewriter off and not let you know what is going on. I've been sneaking around twenty meters lately and I want to let you know that you are missing out. The band has been super in recent weeks, and the DX is rolling in at all hours of the day and night.

Just in the last couple of days, I've had contacts with the following, to give you an idea: ZL2WM, ZL1VY, PY2CYT, PY1BFZ, HR1RBM, 7X2BK, VK6RU, IK7AGT, EZ7BXP, 4Z4JS, EA3CXG, N3RD/VP9, JX1JO, PY0ZZ, HH2MC, TU2HJ, PP6ACP, ZS1DG, ZS6WB, ZS4AF, PR7SSM, S83MMK, TU2LM, ZS6BRD, ZS6BNS, ZS4D, JY3ZH, JY4MB, JY5ZM, YI1BGD, 7X5SI, LX1JAS, Y27FN, Y56FN, SM7DLZ, WB5VIH/DU2, VK6CF, VS6CT, HL9RT, UA0JBN, EA9NG, U9H, UK0SBB, 8Q7AV, 3BD8DB, OD5FB, HZ1AB, 4S7EA, T32AF, F5RV/FC, VU9GI, VU9CK, ZL4OY/A, OH0W. . . and so on.

Besides some bragging about working DX, the above list is indicative of what you can do if you get on the air with a reasonably good rig and antenna. It's there, with thousands of DX operators looking for you. While some put up with contest-style operating, whacking out the contacts for QSLs and the good old ARRL Honor Roll listings, most of them will stop this nonsense and be most interesting to talk with if you ask them some questions. Most of them love to talk. . . and they love most to talk about the most interesting subject in the whole world: themselves.

Think what an impression hamming could make on innocent teenagers if they could hear us talking with Christmas Island out in the middle of the Pacific Ocean! Or some chap in Baghdad! They're there, looking for you. Where are *you*?

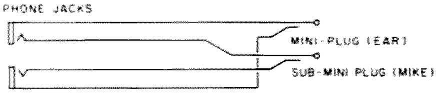
CIRCUITS

Do you have a technique, modification, or easy-to-duplicate circuit that your fellow readers might be interested in? If so, send us a concise description of it (under two pages, double-spaced) and include a clear diagram or schematic if needed.

In exchange for these technical gems, 73 offers you the choice of a book from the Radio Bookshop, *to be sent upon publication. Submit your idea (and book choice) to: Circuits, Editorial Offices, 73* Magazine, *Peterborough NH 03458. Submissions not selected for publication will be returned if an SASE is enclosed.*



"STAR-SET" HEADSET CONVERSION: This adapter will enable you to use "Star-Set" headsets with an Icom IC-2AT (or a similar HT). The IC-2AT has about 1-2 volts present in the mike line to power an external electret condenser mike. This voltage is used to power the "Star-Set" as well. To key the PTT, you use the mike mute switch on the belt clip of the "Star-Set." The PTT works by completing the mike circuit. If you want to use the set on both the radio and a telephone, simply unplug it, because no changes are made in the headset. Use shielded wire in the adapter to prevent rf feedback. If you don't receive anything, reverse the plugs, marking them after you have determined the proper placement.—Joe Eisenberg WAØWRI, Lincoln NE.

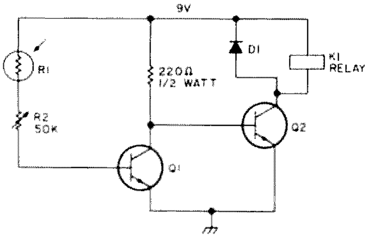


Fig. 1.

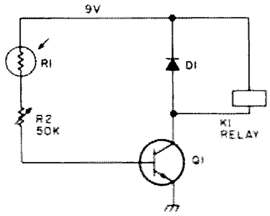

Fig. 2.

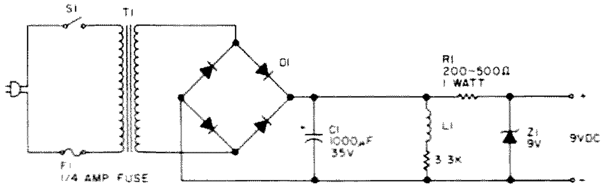

Fig. 3.

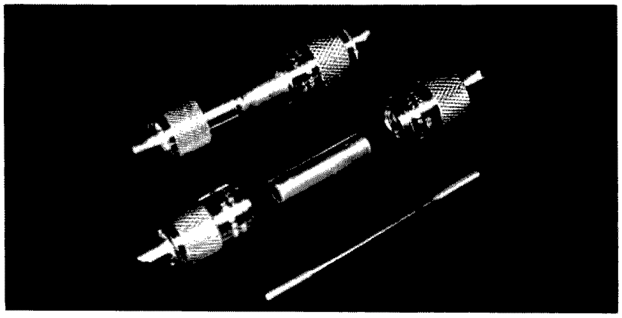
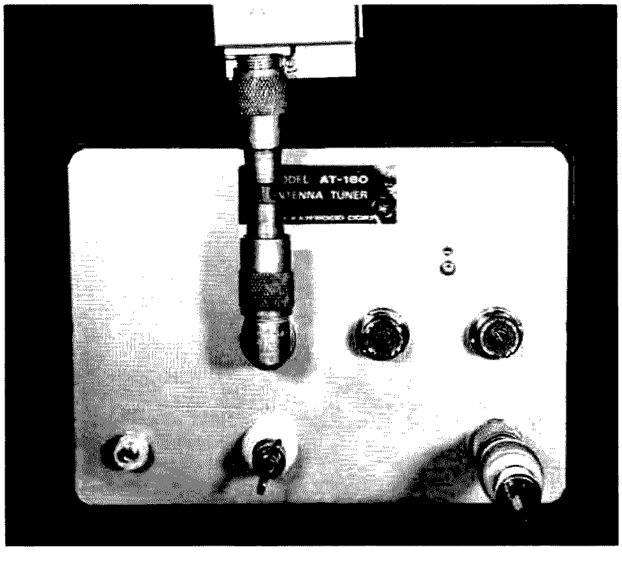
LIGHT-ACTIVATED RELAY: Fig. 1 shows a circuit which will trip relay K1 when the light-sensitive resistor R1 is in the darkness. A buzzer can be attached to K1 to indicate that the lights have dimmed. Any small signal diode can be used for D1, which suppresses the high-current inductive kickback, thus protecting Q2. Any NPN transistor can be used for Q1 and Q2. R1 is a cadmium-sulphide resistor which has 5 megohms resistance in darkness and 100 Ohms' in bright light. The resistor can be located away from the rest of the circuit. Fig. 2 is a light-activated relay; the same components are used as in Fig. 1. A power supply circuit is shown in Fig. 3. R1 is a one-Watt resistor valued between 200-500 Ohms.—Alan Weinberg KR7D, Tucson AZ.

CONVERTING THE DRAKE TR-7 TO RECEIVE VLF WITHOUT THE AUX-7: This is a simple modification for the Drake TR-7 which will enable the unit to receive 0-to-1.5 MHz. Open the unit and locate U9003. Remove the wire from pin 14 of this IC. Carefully solder a 6.5-inch insulated hookup wire to pin 14 and connect the other end of the wire to the unused terminal on the STORE switch. Replace the cover. To receive below 1.5 MHz, you must set the bandswitch to 1.5, press STORE, press the DOWN switch once, and then release the STORE switch. The UP/DOWN switch will now select the VLF band in 1.5-MHz segments. Repeat the sequence, and the unit will then tune 0-500 kHz. The antenna for the lower bands should be connected to pin 7 on the accessories connector (see pages 3-7 of the manual). This modification does not affect the usual operation of the STORE switch.—Andrew H. Kilpatrick K4YKZ, Longwood FL.



RIGID MALE-TO-MALE UHF CONNECTOR: Materials required are two PL-259 connectors, a straight length of no. 10 AWG 3-1/2 inches long, and a straight length of 3/8-inch o.d., 5/16-inch i.d. copper tubing, 1-1/8 inches long. (You can find the tubing in the plumbing department of many hardware stores.) After cutting the tubing, be sure to deburr the inside and outside edges of both ends. Then place PL-259s on either end, connecting the center pins with the no. 10 wire. Solder the assembly together using a large enough iron to avoid cold solder joints.—Gary Legel N6TO, Fullerton CA.



REVIEW

ELECTRONIC RAINBOW SATELLITE TELEVISION RECEIVER KIT

Like a lot of hams who have developed an interest in satellite TV, I have been reading about and watching the market for the last couple of years for a satellite receiver that had all the features I wanted and the right price as well. Most of these factory-wired units' price tags still hung up there in the high dollar range, while kits for these receivers were few and did not enjoy the best publicity from articles I had read. I felt a kit was the best means to meet my end. Having built quite a variety of electronics kits and semi-kits down through the years, I felt that I could handle a quality kit without too much difficulty.

Browsing around the hamfest at Indianapolis back in July, I spotted a few satellite antennas set up around the area and visited each booth to check out their wares. Most of the equipment was factory-assembled, high-priced, turn-key stuff, not for me. Then I happened by the booth where Electronic Rainbow was showing its latest offering to the industry. The owner Ron Ross and I had met at various hamfests and I knew he handled quality products. Ron had his satellite receiver hooked up and it had a crisp, clear picture. I checked the spec and price sheets he had on hand and was very impressed with the features his satellite kit offered, like built-in rf modulator, detent tuning, variable audio from 5.5 to 7.5 MHz, afc, LNA power supply, remote tuning jacks and baseband jacks for the optional remote tuning control, and stereo decoder along with many other features found only on much higher-priced units.

I asked Ron if the units were available yet and he said in a couple of weeks. They were presently getting the assembly manual ready for the printers. I left with an order form and spec sheet so I could review the receiver and make up my mind at home. About a week later, I sent my order in for the kit and looked forward to getting started on my very own satellite TV receiving system.

A few weeks went by and I decided to call Ron and check on my order. He told me that they were just about ready to ship the units with a photocopied manual because the printer did not have the final manuscripts yet.

I immediately saw a chance to get my receiver quicker and help out Ron with comments from the consumer point of view. I suggested that if he could sell me a receiver right away, I would be happy to give him some feedback on the assembly of the units from a builder's standpoint. Ron accepted my offer and I picked up my receiver the next day.

After sorting through the kit and checking parts (a few were missing as we both expected), I dove into the manual and read it from cover to cover, picking out minor errors and missing points that would help a builder do a better job of assembly and ensuring that the unit would work upon completion. I have had a few bad experiences with kits where even experienced builders would pull their hair out trying to figure out the sequence of assembly. This is not the case with the Electronic Rainbow satellite receiver kit. I found the manual to be very easy to follow; there was very little chance for error in the step-by-step assembly of this quality receiver kit.

Fortunately, I had a week's vacation coming and I decided to use it to put together my kit. I was able to assemble the kit in approximately 15 to 20 hours, making numerous trips to Electronic Rainbow for changes in the manual and a few parts that were missing or wrong.

I completed the receiver and was looking forward to checking it out on Ron's antenna, since I did not have one yet. The final alignment was to be done with an actual picture from the satellite. The receiver kit had all the sections, such as the 70-MHz filter, the remote downconverter, and oscillator pre-wired and tested, so final alignment was a simple matter of adjusting the picture, sound, and rf modulator under operating conditions according to the step-by-step instructions in the manual using a VOM to check power-supply voltages.

Even though the main board of the receiver has all the parts on it, the board is divided into six sections with each of the sections having an A and B part for very easy assembly. All the parts are in zip-lock bags for each of the sections of the board, making it much easier to find them.

I had to wait a week or so for Ron's design engineer, Paul Turner, to return from vacation, so his ace assembler, Terri Murphy, and I finished off the few changes in the manual. When the final printing came back from the printer, she could add all the changes to complete and update the fine-quality manual, which was all the individual sections shown in halftones, making placement of the parts on the silk-screened boards a simple matter.

Finally, when Paul returned, Ron asked me over to his shop and the receiver was hooked up along with my downconverter to the bench monitor; when Paul flipped the monitor onto channel 3, there was the picture from transponder 11 MTV, clear as a bell. I was really happy that the unit worked the first time. Paul made his way through the individual trimmers for each of the 24 channels (transponders), peaking and adjusting the sound for a perfect picture on each. He let the unit burn in for about 30 minutes to be sure everything was okay and then put the cover back on the very attractive cabinet. Off I went like a kid with a new toy, proud as could be that my kit was finally ready to go.

In conclusion, I am sure that the Electronic Rainbow satellite TV receiver kit will be a popular item for those builders who have waited so long for just such a product. I plan to use my receiver with a Wilson MD 11 B antenna, Locom LNA, Chapperal super feed, and Beachcraft polarizer. I will be glad to answer any questions about any of these items. Please write only and include a self-addressed stamped envelope.

The complete satellite TV receiver kit costs $395.00. For further information on the receiver, board kit, or manual, contact Ron Ross or Paul Turner at *Electronic Rainbow, Inc., 6254 LaPas Trail, Indianapolis IN 46268, (317)-291-7262.* Reader Service number 477.

ADVANCED COMPUTER CONTROLS' MODEL RC-850 REPEATER CONTROLLER

Imagine, if you will, the amateur repeater that I'm about to describe. It can be controlled via telephone, over a UHF control link, through the main repeater receiver, and, of course, locally at the repeater site. All you need is a touchtone™ encoder and the necessary codes.

If you call the repeater on the telephone, it answers the phone (with a message you've chosen) and waits ten seconds to receive a valid command. After you enter a code, the repeater verifies in voice over the telephone the function that has been selected. It does the same if you enter a command through the main receiver, except that the acknowledgement comes back to you over the air.

If you want to check your touchtone pad, you only need to enter a test prefix followed by a series of keys. The repeater reads your entry sequence back to you, again in voice. And that's only the beginning of what the repeater will do for you. It can evaluate received signals for frequency error, deviation, and percent quieting and give a similar voice response back to the user. Maybe you would like to check conditions at the repeater site from the comfort of your favorite armchair. No problem at all. Just ask the right questions with your touchtone pad and the repeater can give you voltage and power output measurements and also the temperature at the site. It will even give you the time of day!

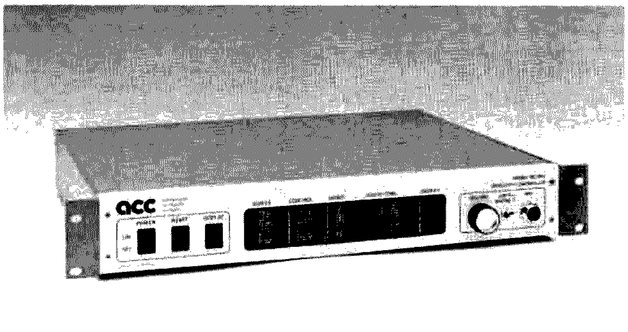
This only begins to describe the features of this particular repeater. Whose repeater is it? It could very easily be yours, just by interfacing your present repeater with the RC-850 repeater controller being manufactured by Advanced Computer Controls of Cupertino, California. And please, don't be put off by the word "interfacing," because in this case you can access most of the features of the controller just by feeding a carrier-operated switch (or relay) logic signal and audio from your receiver into it and by letting the controller feed audio into your transmitter along with a push-to-talk logic signal. Plug the controller's modular jack into a telephone line at your repeater site, supply it with 12 volts dc, adjust one or two audio levels, and you will be able to put much of the power of the controller to work for you right away.

Naturally, other connections need to be made between the controller and the repeater station in order for it to provide received signal reports and other voice response telemetry (VRT) information about the repeater itself. You can even connect the controller's logic outputs to a synthesized transceiver and operate a remote base station, *complete with frequency selection*, through your repeater. This makes it simple to link up with another repeater for nets or public-service activities.

Software-Based

The controller itself, even without the synthesized voice capability, offers features which to my knowledge are not available in any other commercially-manufactured controller or repeater/controller combination. The key to the power of this unit, and the thing that enables ACC to expand the controller's features on a continuing basis, is that it is software-based (or, to be technical, firmware-based in the form of several EPROMs). New releases of the operating system software can enhance the capabilities of your machine, in many cases without any additional wiring or work on your part beyond changing out the EPROMs. It also makes it possible for the manufacturer to incorporate into the controller some additional feature which may be very important to you.

The Blue Knob Repeater Association, which sponsors the highest amateur repeater in Pennsylvania (147.75/.15 MHz), had a special problem which ACC was able to solve through a small amount of



The RC-850 repeater controller from Advanced Computer Controls.

additional programming (which then became available to every user of the controller through an upgraded release of the software). Most of us are familiar with just dialing (or pressing) the number "1" to access the nationwide long-distance telephone network. However, there is a fairly rural telephone system operating at our site on Blue Knob Mountain, and it requires entering "1121" to make a long-distance call. Couple this with the fact that most of our members live outside the local calling area from the exchange at the site and you've got a cumbersome number of digits to enter when operating mobile, a number which can rise to 14 digits in order to place a call outside our own area code. What made this even worse was the fact that while the controller has the capability to store up to 90 telephone numbers in its user autodialer and 10 numbers in its emergency autodialer (these numbers can then be called just by entering an access prefix plus two digits), the storage locations are limited to 11-digit numbers at most. This would present no problem for the typical long-distance number, but it would have severely limited the usefulness of the autodialers in our system. Ed Ingber WA6AXX, who founded ACC, solved the problem just by programming the controller to "see" a leading "1" and substitute an alternate sequence when the number is dialed out (in our case, "1121"). This small change, which was relatively easy to handle by modifying software, would have been far more difficult, if not impossible, in a hardware-based system.

The controller's autopatch, which is logically separated into three different components (basic autopatch, user autodialer, and emergency autodialer) is extremely advanced in design. Phone numbers are read back to the user for confirmation (in voice with the voice-response option installed, and otherwise in CW) before a call is placed. The controller itself enters the number into the landline system in your choice of ten pulses per second, twenty pulses per second, or standard touchtones. This greatly increases the reliability of the autopatch, since tones are not being passed from many different user's touchtone pads directly into the telephone system.

The user autodialer codes can be programmed by the members themselves, or the user autodialer can be "locked" so that only control operators can load and change the telephone numbers to be stored. The access prefix for the autodialer can also be changed if and when necessary.

The emergency autodialer provides for the storage of 10 public-service telephone numbers and associated response messages for each agency (such as "Fire").

With the voice-response option, the reverse autopatch (which requires entering a code sequence after calling the repeater on the telephone) can actually call a repeater user *by callsign*. Forty callsigns can be stored in the controller's memory for use with these directed reverse autopatch calls (or as part of a demonstration message).

Separate timers can be set for each type of autopatch call, and the three functions can be enabled or disabled separately. This can be used as a way of allowing emergency calls to be placed at night, while the other autopatch functions might be turned off. A programmable activity timer functions with all autopatch calls to drop the patch if no activity (or constant keying) comes from the repeater user for the designated period of time.

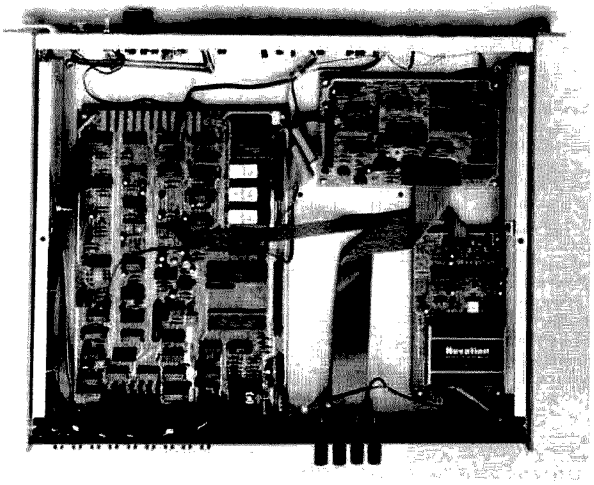
It's also possible to place a full duplex autopatch call (for simultaneous receiving and transmitting) and a semi-private patch where the repeater-user side of the conversation is not fed through to the transmitter, but instead is replaced with a "cover tone" to alert other users that a call is in progress. If your repeater suffers the misfortune of having someone maliciously dropping the autopatch on legitimate users, you can program the controller to allow *each user* to define his or her own custom hang-up code just before placing a call. Then, only that code or the control operator's override code will terminate the call.

Long-distance calls can be prohibited on the main autopatch, which then allows the entry of a 7-digit number only, which cannot begin with "1" or "0." There is even an "antidialer," which can be loaded with up to five telephone numbers which may *not* be called on the autopatch (such as a local pizza parlor?).

One convenience which anyone who has ever used an autopatch will appreciate is that the controller will give the time and date for you automatically upon completion of a call. This is also very helpful to the repeater owner for the proper logging of autopatch calls.

Identification, Please

The controller handles repeater identification requirements in a similarly sophisticated manner. An "intelligent" ID algorithm directs the unit's handling of several different ID messages in accordance with the activity on the machine. For example, if the repeater has been dormant and is then keyed up, an initial ID (typically a voice greeting) is given. As time progresses from the initial keying of the repeater and with a QSO in progress, the controller will wait for an opportunity to ID again when a user lets the repeater carrier drop. If this opportunity doesn't occur, then the unit becomes anxious to ID, but will still try to avoid IDing over the top of a user transmission. But, if ten minutes pass without even a break in the QSO, then the controller will do a forced CW ID over the top of the user, but at a fast, unobtrusive level.



Interior view of the RC-850.

With the voice-response option, you can use the built-in message editor, either on site or remotely, to program the messages you want for IDs and other responses. The controller has a vocabulary of over 200 letters, numbers, words, and sound effects. You can even have custom words, such as your group's name or location, merged into your controller's software, but these words are not cheap at $200 each!

Probably the second most remarkable feature of the RC-850 (I'll save the first one for later) is that all of your repeater's operating parameters, including timers, courtesy tones (you can select from eight sets that you program yourself), messages, autodial numbers, control operator and user codes, and even an initial power-up configuration (in case power to the unit is temporarily lost), can be changed *remotely*.

Non-Volatile Memory

If you're like me, you're wondering now what happens to all of that information stored in the controller, including the 90 user autodialer numbers and 10 emergency autodialer numbers, if power to the controller does fail. Incredibly, absolutely none of this data is lost, because it has been stored in EEPROMs (Electrically Erasable Programmable Read Only Memory) by the controller's own built-in programmer/eraser. The controller will "awaken" according to the configuration you've programmed as soon as power returns. And, by the way, battery backup circuitry is included in the unit.

Other standard features include several modes of operation based upon a subaudible tone input, touchtone up/down access by users with programmable automatic timeout, logic outputs for remote control of other devices (complete with response messages to indicate their function in your system), provisions for a control receiver, a kerchunker filter that can be switched on or off, spare audio inputs, tone signalling, and a host of others literally too numerous to mention in this review.

One extremely clever feature of the controller is that it suppresses the squelch tails of user transmissions (which makes listening comfortable for users and control operators alike) and also, at your option, touchtones. It does this through the use of a 75-ms analog delay line which allows the controller to cut off audio to the transmitter when the carrier-operated switch signal disappears or when touchtones are properly decoded by the state-of-the-art Mitel chip set. Without actually hearing it operate, it's hard to believe how effective this circuitry really is.

Construction

A review of a product such as this one wouldn't be complete without some description of how it's constructed. I can honestly sum it up with one word: impressive. Machine-contact IC sockets, fully sealed, are used throughout the controller. Signal connectors are gold on gold for long-term reliability. The circuit boards are computer-grade glass epoxy with through-plate holes. They are solder-masked and silk-screened with component designations. And, finally, low-current CMOS circuitry provides highly efficient operation.

Product Support

Another important plus is that the device is fully documented with a comprehensive owner's manual which includes a description of the unit, how to install it, how to operate it, service and maintenance information, and schematics and parts placement drawings. The manual makes liberal use of figures and tables. It's clearly written, but don't expect to skim through it once or twice and completely understand the operation of the controller. Careful reading is necessary due to the many advanced features of the unit.

From my own experience, however, by far the most impressive support for the product comes from the designer himself. Ed Ingber WA6AXX is an electronics engineer, and his background (which includes a Master's Degree) lies primarily in designing test equipment, programming microcomputers, and working with speech synthesis. I have been able to reach him by telephone (he provides owners with both his factory and home numbers) any time our group has needed information or assistance.

I mentioned earlier that I would save the most remarkable feature of the controller for last, which is that *it works just like the manual says it will* (the manual can be purchased by itself for $30), and it sounds terrific on the air. The speech synthesis is so good that during the first few days that we had the controller on-line, we actually had people responding to the female "Good Morning" greeting with a complete rundown of their name, location, and other information, only to be tremendously sur-

prised to learn that they had been talking to a computer!

Few Problems

In our controller, problems were hard to find, and I heard essentially the same thing from other owners before we made our decision to purchase one. Our unit was shipped with an interim version of the controller's operating system software designated as 1.4X, and this version did have a few bugs in it. One example was that giving the controller the code to disable the autopatch *timer* disabled the autopatch itself. Another bug caused two of the front-panel display LED indicators to be reversed. In a way, though, these problems actually point out the strengths of a software-based device, because the final release of this version of the software corrected both of these glitches.

If you haven't guessed by now that the price tag for one of these controllers is pretty hefty, then you might consider price alone to be a drawback. Actually, the RC-850 controller comes in a number of different configurations, ranging in price from $1195 for an assembled and tested control circuit board only up to nearly $2800 for the maximum system, which includes an FCC-registered telephone interface, voice-response telemetry option, and front-panel display option, all contained in a rack mount cabinet ready to install at your repeater site. There are also several versions between these two extremes. For example, you may want to provide your own telephone interface, which reduces the cost of the unit by $349. Or, while you might want to have synthesized voice IDs and the time-of-day clock, you may not really need the 16-channel analog measurement and speech-readback capability provided by the complete VRT option. This would also reduce the cost of the controller. And, it's good to know that you can start out small and expand to a maximum system at a later time with very little difficulty, since the control board has been designed to be upward compatible.

If you want to significantly enhance your repeater's capabilities and at the same time *infuse your organization* with new enthusiasm and excitement, the RC-850 repeater controller may well be just what you're looking for!

LJM2RK STORM ALERT

My wife does not like ham radio. She despises the funny noises my radio makes, and she would really rather it didn't ride in the car with us. So, I find myself and my rig relegated (or maybe I should say "banished") to a remote corner of the basement.

Now, I don't mind being in the basement, but I'm an Army officer whose specialty is tanks. That means, after years of firing tank guns on various ranges in combat, I'm rather hard of hearing. Consequently, I can't hear when someone is calling me unless I'm right at the radio, and, while I'm a pretty avid ham (my wife thinks too avid), I do occasionally go upstairs to get a cup of coffee or take care of the effects of an earlier cup. So, I've been looking for months for a simple (and affordable) tone decoder I could put on the two-meter rig to alert me to calls. I needed to be able to set up a visible signal to alert me when I was copying CW traffic on the HF bands (since I wear headphones to muffle the sound of the "mill"), and an audible alarm to call me when I was elsewhere in the house. I also needed to mute the audio, since my wife does not have a hearing problem and would have fits on those occasions when the repeater was really busy.

It didn't take me long to find that a simple tone decoder, even if you elect to just buy the parts and home-brew it yourself, isn't all that cheap, while ready-made or kit decoders are downright unreasonable ($50.00 plus is the normal range). I had finally decided the *only* way out was to home-brew one, with the attendant costs involved in making a circuit board and the costs in time to construct it, when I happened to stop at a hamfest in Lafayette, Indiana.

At one of the booths, a guy (whose name I never did get) was demonstrating something that caused alarms to sound and strobe lights to flash. Intrigued, I stopped to watch what turned out to be a demonstration of exactly the thing I'd been looking for.

He was demonstrating a tone decoder—he called it the "LJM2RK Storm Alert"—in nine different configurations. Each of the nine circuit boards was attached to a big board and each was wired for a different option. All nine were essentially the same—only a few jumper wires were different. The same board, ICs, resistors, etc., were used in each one, and each was constructed exactly the same, except for the jumpers. When the guy running the show told me they cost only $15.00, I picked up two. I had already proven that parts alone would cost that (not counting the cost of constructing a circuit board and my time to find all the parts).

Once I got home, it took me about 45 minutes to build the first one, most of that time spent locating the parts on the board. The second one took about 20 minutes. For such a little company, the kit is a real joy to build. The written instructions, while not elaborate, are more than adequate, and the circuit board is beautifully silk-screened with both a drawing of the component and its reference number (R1, C3, etc.). Orientation of every polarized part is shown on the board and referenced in the instructions.

In only one case are the instructions a little remiss. Two of the LEDs have to be mounted with nylon spacers (if you use the company enclosure). The instructions mention that in passing, but when you go down the list of parts to install, as the instructions suggest, the spacers are listed well after the LEDs. It would be wise to write in "spacer" next to the LED listing, although it won't damage the operation of the device even if you forget the spacer. It just won't fit as neatly in the enclosure.

Once the boards are finished, aligning them is even simpler than building them. First, apply an audio source to the decoder. If you use one of the Metheny enclosure kits, that simply means plugging the thing into the speaker jack. Then attach a power lead and have someone generate a tone. I did mine by hooking my HT into a dummy load and the decoder into my Wilson WE-800. If that is not sufficient attenuation of the signal, leave the antenna off the receiving unit or attach it to a dummy load. At any rate, that hookup attenuated my 100-mW signal enough to allow me to align the decoder. A buddy at the other end of the repeater can do the same for you, if you'd rather.

Transmit the tones you want (I used the number 9, since the local RACES net uses that as an alert signal) and adjust a simple pot for tone B (it's well marked on the board) until an LED on the board lights. (They have thoughtfully provided this LED just for alignment.) Then, still applying the tone, adjust the pot for tone A until another LED comes on (you'll be able to see this LED even after you put the device in the enclosure). The decoder is now aligned and all you have left to set is the delay. Another little pot allows you to set in a delay so the decoder will not do its thing until the tone(s) you choose have been applied for whatever time you want. I use one second, but you can go from instant on to a very long delay.

Electronically, the device is equally simple. It uses two 567 tone decoder ICs, one to control each tone, and then feeds them to an LM7402N quad 2-input NOR gate. Each 567 is adjusted to one of the required tones by varying a single potentiometer (you could easily change the frequency range by modifying the value of the capacitor on the circuit, but since the thing already operates on all the touchtone™ and likely PL® frequencies, you will need to do that only if you use really exotic tones). When the first 567 is triggered, it lights an LED and signals one of the LM7402 gates, which waits for the next 567 to decode the other tone (when using the two-tone option). Once the second tone appears, the gate opens, lights a second LED (labeled "decoding" on the Metheny enclosure), and provides the logic state that causes the LM7402 to activate the delay and, finally, the relay. If either tone is removed too soon, the delay resets. Once activated, the relay does whatever you wired it to do, the usual task being to connect the speaker to the audio line. All the components, save the circuit board, are generally available at well-stocked Radio Shack stores, so repairs should be especially easy. The Metheny enclosure also has a couple of well-placed mounting holes in it to allow attachment of the power source and an external relay, driven by the on-board relay.

Now, let's see what else this thing will do. It has an on-board relay, so the control possibilities are almost unlimited. You can have it take two tones (standard touchtones) to open the audio on your transceiver so the thing stays quiet until you are called. Or you can have the relay sound an alarm or turn something on or off (great possibilities for a repeater system). Metheny even provides a suggestion for a simple timing circuit that will automatically reset your decoder after a preset delay. You can also set it up so one tone turns it on and another turns it off, or one tone turns it on and leaves it on. Delays can be worked on both ends. It can also be set up to turn on with a subaudible tone and off when the tone is removed. And, by changing a single resistor, you can use 12-V-dc, 9-V-dc, or 6-V-dc power sources. *All the required controls mount right on the board and are included in the kit.*

You can also do a number of other things not mentioned in the Metheny instructions—*your imagination will be your* only real limitation. With two boards, you can use one dual tone to turn a device on and another to turn it off (retaining all the

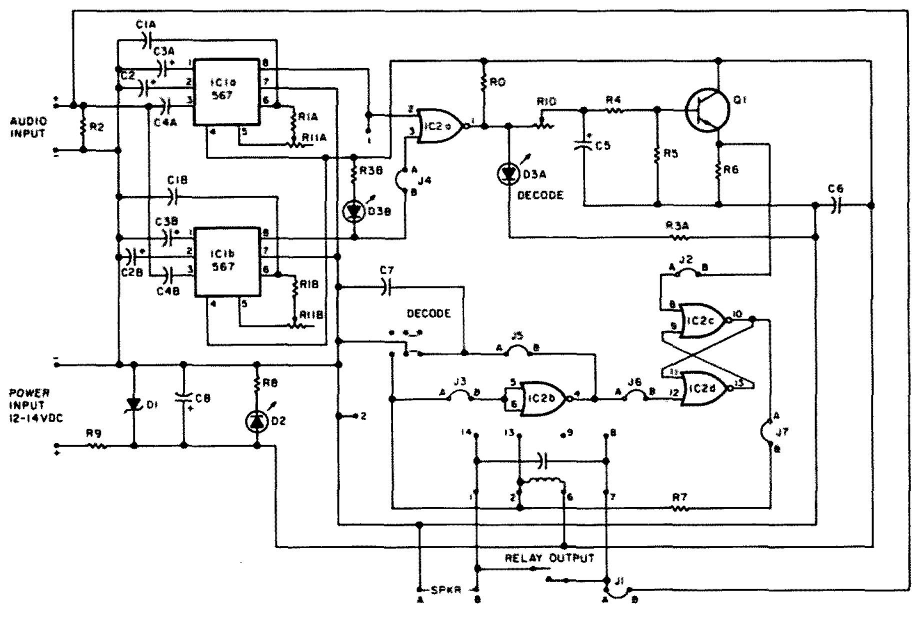

Fig. 1. Schematic.

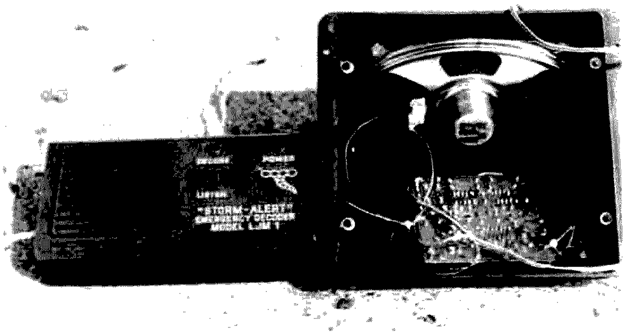
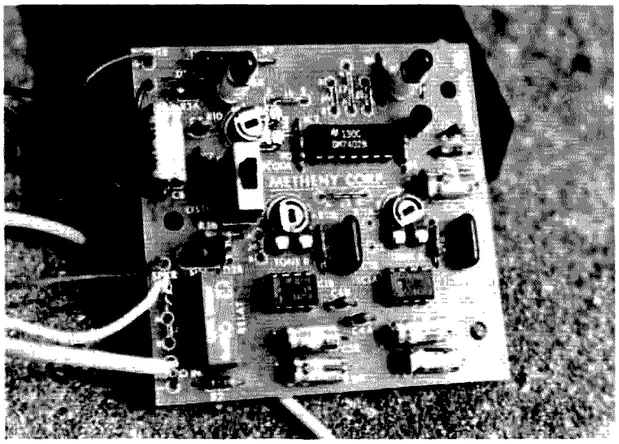


The front side of the Metheny enclosure, next to the speaker case.



The decoder itself. Note that while it does not leave a lot of wasted space on the board, there is sufficient room to work comfortably.

usual options for each tone) With one board, you can even use sequential single tones with a delay In this case, a single pot would establish the delay so that, in effect, the device will require that you input both tones within two seconds, or three, or whatever period you program. Using multiple boards, you could do the same thing, but with variable delays between selected digits to safeguard your autopatch from the guy who breaks your code (he's not likely to catch on to the variable delay idea) And if you use the Metheny enclosure, it is easy to add a battery pack, hang it on your belt, and have an inexpensive tone-accessed HT. Or you could forego the speaker and package it in an even smaller enclosure.

It is really nice to see a little outfit like Metheny offer a really useful and inexpensive device like this. If only we had more such little companies in ham radio.

The LJM2KR (I have no idea what those letters mean) is sold for $15.00 plus shipping. The "Storm Alert" enclosure is available for $5.00 plus shipping and includes speaker and patch cable. For more information, contact the *Metheny Corporation, 204 Sunrise Dr., Madison IN 47250.* Reader Service number 478.

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

Happy New Year! I do hope the winter is going well for all of the readership, with projects underway and the like. One such project we have been dealing with in this column has been the design of a computer-based RTTY terminal. This month, another installment: character input and control mechanisms.

It should be obvious that in any complex system there is a need for suitable control mechanisms. Now, while we are not talking about Three-Mile Island here, with a computer-based RTTY terminal there is a need to direct the data flow, fill or empty buffers, change speed, etc. If the terminal being designed operated only on Murray, the job would be relatively easy. The ASCII character set, which most computers use, supports many more characters than could ever be sent on Murray. It would be easy, therefore, to use any or all of those codes, such as control codes, special punctuation, or even lower case, to implement some of these special functions. In fact, an earlier terminal I designed did just that.

However, when designing a terminal which will be able to operate on any of the several modes, including Murray, ASCII, or even Morse, using these extra or control characters becomes difficult, if not impossible. A glance at some of the specialized RTTY terminals on the market reveals the presence of several function switches on the keyboard. These function switches do not send out one ASCII character, but a sequence of characters which can command a task to be carried out.

Such a sequence of codes is normally preceded by the ASCII "ESCAPE" character. Normally abbreviated ESC, this character is 27 in decimal, $1B in hex, or 00011011 in binary. As defined in the ASCII standards, the ESC character is used to shift into another character set, or code grouping. We can use it, as many terminals do, to indicate to the program that the character(s) which follows is not to be sent, but to be treated as a special command.

Once such a protocol is adopted, an essentially infinite number of command sequences become possible. For example, ESC-F might be used to fill a buffer and ESC-S to send it. Numbers appended to the command could denote one of a series of buffers, such as ESC-F-7 to fill buffer number seven. As we have been looking at the design of an "ideal" RTTY terminal, such a technique would appear to fill the bill nicely.

Implementing this scheme is not as hard as it might sound. Fig. 1 is a flowchart of the way a character, once received from the keyboard, might be screened for a command sequence. By use of a flag, input which follows an ESC character can be diverted to initiate the appropriate command sequence. I will add here, for the smarties among you who are worried that you won't be able to send an ESC out over the air even if the distant station requires it because it would be trapped in this sequence, that the command ESC-ESC is normally configured to send the ESC code out. Does that make you happy?

Combining this command input routine with the receive and screen display routines presented in previous months begins to suggest just what this terminal will be able to do. Additional modules will be presented in the months to come, don't worry.

I have a panic note here from Roy E. Denney N5DQX of Roswell, New Mexico. Roy bought a "Transcillator," Mod ZUH II, at a hamfest, and despite being told that it was in fine working order, it isn't. Now, I don't know what this beast is, and Roy notes that the manufacturer, Prossen Industries of Westminister, California, is apparently out of business. I presume it has something to do with RTTY, and so does Roy, and we both address the readers of this column to scrounge around and see if something can't be turned up. If so, send it to me and I will see that Roy gets it.

Thanks to Winston Yancey WA4TFB who relates that RTTY Loop is the first thing he looks for in *73*. He notes being upset if we miss a month and wonders why that happens. For those of you not fully acquainted with the schedule a magazine such as *73* must follow, there is a two- to three-month delay between when I write a column and when you read it. Since I try to delay until just before deadline to keep the material as topical as possible, it becomes very sensitive to unscheduled delays, such as demands from my work (I am a physician in active practice here in the Baltimore area) or family. Hopefully, that's not too often, but it will occasionally happen.

Winston also relates trying to interface his Texas Instruments TI-99/4 computer for RTTY. Apparently little in this vein is available through the users group. I must say that I have noticed TI-99/4s being widely marketed, from computer stores to discount outlets to toy stores. I'm sure somebody out there is writing software that would be useful to the RTTYer, if only we can find it. Hopefully we can collect some here and display it for all to see in a future column. Are you listening, TIers?

Greetings to Kevin A. Muench, Ph.D., a RTTY buff working in the Philippines. He is attempting to interface a Flesner TU-170 to a Teletype* Model 33 and is looking for help. I am afraid that the TU-170 is another piece of equipment I have very little information about, but it is widely used and I am sure someone out there has already accomplished such a mating. If so, let me know so that I can send the details along to Kevin. I am sending Kevin some other material on the 6800 programs detailed here in the past. I am sure that with his 6800/6809 system, Kevin will be interested in following the current "super-terminal" series as it develops.

From one end of the world to another, I have a letter here from John M. Clarke VO1EE, Newfoundland, who is having problems of a different sort. John has been working on the LNW-80 computer and, after building the boards, apparently has trouble getting the thing to work right. He's unable to obtain a good display and thinks that the onboard regulators are running too warm.

Well, John, I will offer two words of advice. First of all, regulators usually run warmer than you think they should, but rarely are they hot. If they are too warm to touch comfortably, something may well be drawing too much current. Which brings me to my second bit of wisdom.

Projects which come on printed circuit boards, especially widely-marketed and complex ones like computers, are usually well designed if they come from reputable manufacturers. In the case of the LNW-80,

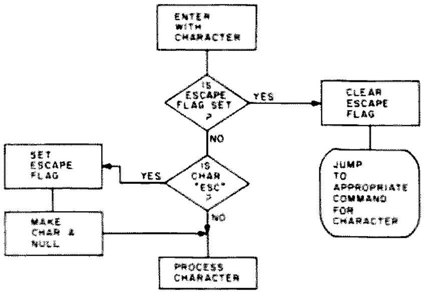

Fig. 1. ESCAPE code processor flowchart.

this is a widely-marketed piece of equipment which has received good reviews. Problems such as you describe can be traced to anything from an integrated circuit installed backwards (that is, 180 degrees out of phase—don't tell me it can't happen, I've done it!) to a solder bridge between two printed circuit tracings (ditto!). The critical thing about this is that if something "happened," the result may be remedied easily by reversing the integrated circuit or clearing the bridged conductors. But circuit damage could be temporary or permanent. If the former, fine, but if the latter, you are in for a lot of headaches unless you really know your way around a circuit.

The moral of this story, if there is one, is to check all the work out *very carefully* for integrated-circuit placement, solder bridges, unsoldered pins, or misplaced plugs *before* you apply power. If something is not working right after power is applied, *stop right there!* Cut the power to the circuit and check again. If you find an error and correct it and the unit still does not function or if you are unable to locate any mistakes at all, seek expert guidance. This may be a friend who has a similar device or the expertise and equipment to troubleshoot complex digital electronics. If all else fails, write a clear description of your problem to the manufacturer, including the model and serial number of your unit. After all, changes in printed circuits or designs may make an early production run and a late one two different animals, and in order to help you, the manufacturer needs to know what you have, what the problem is, and any information such as measurements or the like which will aid in diagnosis. Do not just bundle up the unit and ship it back without the manufacturer's consent unless their book tells you that you can. Doing so will only prompt the string of letters that should have preceded and may have prevented the shipment.

While we are up north, regards to another newcomer, Irvin F. Haworth VE7CVL from West Vancouver, B.C. Irv has a rather complete Apple II setup which he wants to try on RTTY, and he wonders how to proceed. Well, by now I hope Irv has read last month's column with its raft of sources for Apple (and other computer) interfaces. You might ask around in your area to get a feel for what others are using, then visit their shack to see how the various units operate. Let me hear from you when you get on the air, OK?

My Atari 400 is coming along, for those of you who have asked, although it's not yet "on-line." I will be looking into various interfaces and the like in the coming months and will pass along any tips on what I find. I have also been looking into buying eight-inch disk drives and have been having a rather interesting time with a dealer. No details right now, just a caveat to be sure that what you order by mail is really in stock and shipped. It appears that the back-order is a way of life for some mail-order houses. I will pass along more information if the situation warrants it. Stay tuned to this magazine and don't miss next month's RTTY Loop!

FUN!

THE YEAR IN REVIEW—1982

Like most years, 1982 was a year of turmoil. In ham radio and the rest of the world change was in the wind. Proposed massive FCC rule changes and the advent of microcomputers were just two areas that may mark 1982 as the year ham radio embarked on a new era.

This month's FUN! takes its annual look at the year just gone. How much can you remember?

ELEMENT 1—CROSSWORD PUZZLE (Illustration 1)

Across

1) Craft announced last year as a 1983 DXpedition site (2 words)
7) CW salutation (abbr.)
8) Critical sunspot point (abbr.)
9) Prompt or pool stick
10) Harvest
11) Pacific prefix
12) Problem
13) Satellite TV (abbr.)
15) Least-crowded DX time
17) Prosign
19) Half a headset
20) Slang for FCC rule
22) Interference (abbr.)
23) Whatever number
24) Your residence
25) What a jammer usually gets on his face
28) Former ARRL president (2 words)

Down

1) Not ordinary
2) Popular 1982 ham accessory
3) New ARRL General Manager
4) Above VHF (abbr.)
5) Potential no-code license class
6) Earthquake, fire, etc
7) ARRL listener (abbr.)
11) Standby
14) Peru prefix
16) In the airmobile (abbr.)
18) Man who signed new communications bill
21) Avarice
25) Listening organ
27) Summer contest (abbr.)

ELEMENT 2—MULTIPLE CHOICE

1) The year 1982 witnessed one of the greatest turnovers in ARRL upper-level personnel in quite some time. By now, we all know that Vic Clark is the League's new president and Dave Sumner the new General Manager. What, however, was the fate of Richard Baldwin, the old General Manager?
   1) The job of ARRL International Affairs Vice President
   2) The job of ARRL Secretary
   3) The job of ARRL TVI Task Force Chairman
   4) No job
2) What was last year's big news from the Heath Company?
   1) Heath's withdrawal from the amateur radio marketplace
   2) The introduction of Heath's first non-kit amateur transceiver
   3) The introduction of Heath's first solar-powered radio
   4) None of the above
3) Last year's amendment to the Communications Act of 1934 will permit the FCC to perform which of the following actions:
   1) Complete elimination of all code requirements
   2) The addition of a new satellite band
   3) The delegation of amateur testing to local radio clubs
   4) Last year's amendment gave the FCC no new powers

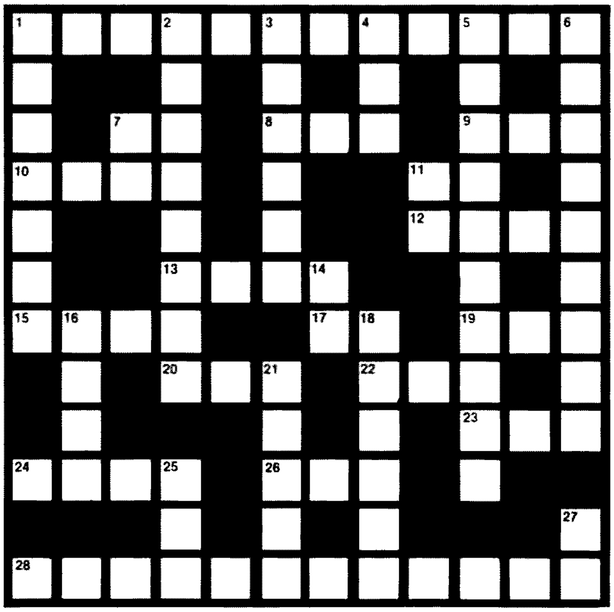

Illustration 1.

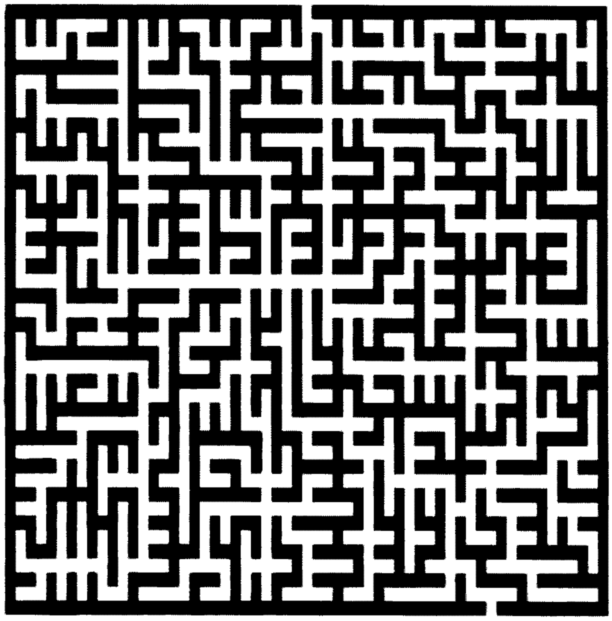

Illustration 2.

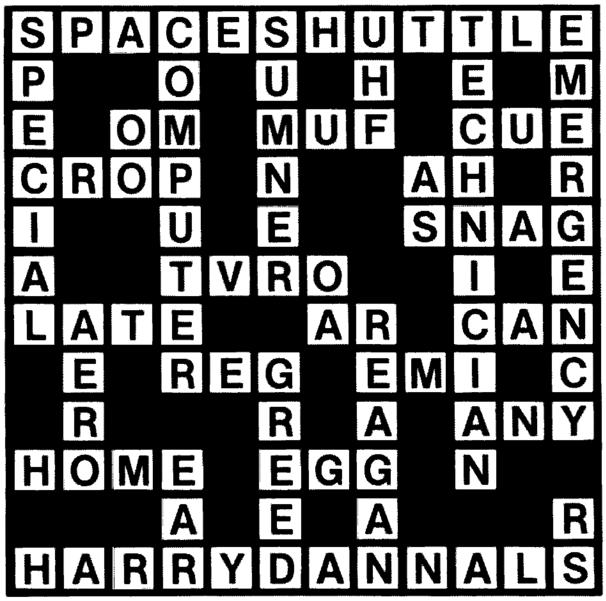

Illustration 1A.

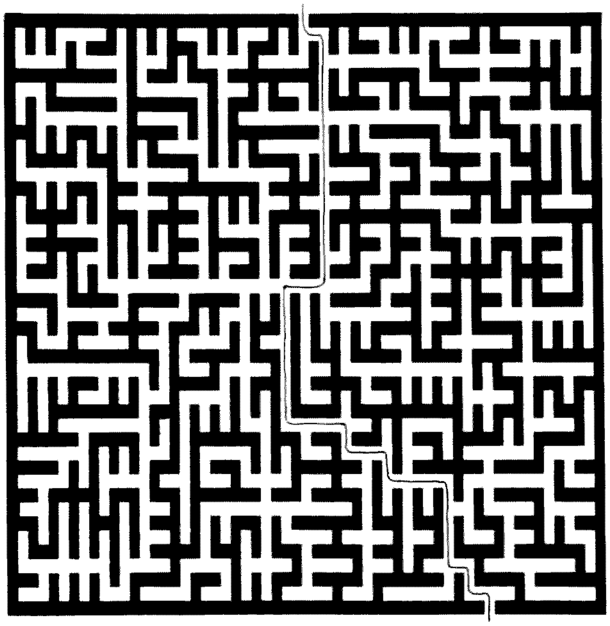

Illustration 2A.

4) Which of the following countries reached a third-party agreement with the US during 1982:
 1) Spain
 2) Austria
 3) Sweden
 4) Australia

5) What did the FCC plan to do to our phone bands in 1982?
 1) Expand them
 2) Contract them
 3) Eliminate them
 4) Leave them alone

ELEMENT 3—CRYPTIC PUZZLE

By using a standard substitution code, decipher this message: YMUDV CEQ YMJV QHCK QCO KFH MO M JMZKW SWKUDVJ DMOC LVMW

ELEMENT 4—MAZE
(Illustration 2)

Did 1982 leave you confused? Join the club. This maze certainly won't make you any less dizzy, but at least it isn't very difficult.

THE ANSWERS

Element 1:
See Illustration 1A.

Element 2:
1—1 The man's too young for retirement.
2—2 The SS-9000 computer-controllable rig.
3—3 Soon, perhaps, no more trips to the Federal Building.
4—4 Down Under was the place.
5—1 Much to the irritation of most foreign hams.

Element 3:
Coded as follows—

A	B	C	D	E	F	G	H	I	J	K	L	M	N	O	P	Q	R	S	T	U	V	W	X	Y	Z
M	U	Y	B	V	P	A	X	Q	Z	I	D	J	H	K	S	R	W	O	C	N	E	F	T	L	G

"CABLE TVI CAME INTO ITS OWN AS A MAJOR PROBLEM LAST YEAR."

Element 4:
See Illustration 2A.

SCORING

Element 1:
Twenty-five points for the completed puzzle, or one-half point for each question correctly answered.

Element 2:
Five points for each correct answer.

Element 3:
Twenty-five points for the completed puzzle.

Element 4:
Twenty-five points for the completed puzzle.

How well did you remember '82?

1-20 points—Skipped the year
21-40 points—Not very well
41-60 points—Bits and pieces
61-80 points—Very well
81-100+ points—Total recall, proceed to '83

FUN! MAILBOX

I just got to the June issue of *73* and began your logic puzzles. Element 3, DXX Couples is incorrect by your solution as Diane has 206. You say Diane is Stan's wife, but that Frank's wife has more countries than Stan's wife. Therefore Stan's wife cannot have the highest total. It was given that Diane had 206. The correct solution is:

Stan 198, Wilma 202—Total 400
Frank 194, Diane 206—Total 400
Joe 196, Susan 200—Total 396
Stan has 198
Joe has 196

Bob Gingras WB4JMH
Cocoa Beach FL

Very good, Bob. Don't you like the way I mess up answers just to keep my readers on their toes?—J. E.

CORRECTIONS

In the "Automatic Beam Aimer," which appeared in the November issue, there was an error in the schematic on p. 23. The diodes across K1, K2, and K3 were drawn in the opposite direction from what they should be. In the parts list on the same page, Radio Shack part number 271-1715 refers to a 25k pot. Actually, part 271-1715 is a 10k pot, but it will work equally as well in the circuit.

Avery Jenkins WB8JLG
***73* Staff**

Our apologies to Steven Katz WB2WIK, author of "Build Yourself A Paralyzed Beam" (December). Readers might better view the photo of the relay box on page 24 by turning the page upside down.

Avery Jenkins WB8JLG
***73* Staff**

Several errors crept into the "Circuits" feature in recent months. In the September, 1982, issue on p. 92, there were two errors. The first occurred in the description of the "Visual Adjust for Gamma Match," with the sentence beginning, "Even if you use an swr meter at the transmitter end of the scale. . . ." It should read, "Even if you use an swr meter at the transmitter end of the cable. . . ." And in the description of the "Electronic Phone Bell," "heat-sink tubing" should be heat-shrink tubing.

On p. 109 of November's issue, there were two errors in "Substitute Transformer for Heath Gear." Circuit author Terry Martin points out that the circuit is a voltage tripler, not a voltage doubler as stated in the text. He also adds that it supplies 950 V, not 450 V.

On p. 112 of the same issue, in "Modification to the Kenwood TS-520S for AFSK," Fig. 3 was incorrectly labeled. Fig. 3 shows the i-f filters of the 530S, not the 520S as implied by the text.

NEW YEAR'S RESOLUTIONS

The new year always provides a good time to review operating practices and perhaps improve techniques on the air. Here is my list of New Year's DX resolutions; why don't you come up with your own list and post it next to your rig!

1. I will not tune up on the air without checking the frequency. Instead, I will use a dummy load, mark the controls for each band, or search for a clear frequency before tuning up.

2. I will listen carefully before I call. No more "Who did I just work?" or calling out of turn when the DX station is working by call areas.

3. I will keep well informed, so that I don't have to ask "What's his QSL address?" in the middle of a DX pileup.

4. I will not be a "DX hog." I won't flaunt my (multi-)kilowatts in pileups and then ask the rare DX station to run a few tests with different antennas, etc.

5. I will not be a self-appointed policeman on the DX bands, nor will I talk back to one. The bands are crowded enough without this nonsense.

6. I will keep my transmissions short and listen often, to reduce QRM.

7. I will be courteous at all times to my fellow DXers, no matter what they do.

8. I will QSL promptly, with the card carefully filled out.

9. I will check out my rig to ensure that my signal is clean and not causing QRM.

10. I will try other bands and modes and not sit on 20 SSB.

If we all follow these resolutions, we will have an easier and more pleasant DX experience in 1983. And we'll need every advantage we can get for the big pileups around Heard Island early this year.

HEARD UPDATE

The race is on to Heard Island. One of the most difficult and expensive DXpeditions continues its relentless drive towards this isolated rock (see this column, September, 1982), as the members of the VK6 DX Chasers Club nail down many of the details of the trip.

At the same time that the VK6 DX Chasers are organizing their trip to Heard, the well-known South Pacific DXer, Jim Smith VK9NS, has chartered his own transportation to Heard. Jim sports an impressive record of successful DXpeditions throughout the region and is as knowledgeable and experienced as any DXpeditioner. Jim aims to arrive at Heard a month before the mountaineering group. So after years with absolutely no activity, it looks like Heard might be the subject of not one but two DXpeditions.

As of press time, the operators on the VK6 DX Chasers DXpedition are slated to be: Alan Fisher N8CW, Charles Brady N4BQW, and David Shaw VK3DHF. Alan is a mechanical engineer, which is likely to be a very useful talent on icy, wind-swept Heard. N4BQW is a physician when not DXing, and one hopes *his* specialty will not be needed on this DXpedition. The Australian on the DXpedition team has worked with the Australian meteorology department as an electronics technician. Both meteorology and electronics will certainly be needed on Heard Island.

The vessel taking the hams and mountaineers to Heard is as impressive as the list of operators. The *Anaconda II* is 84' long, 20' wide, and sports a 98' main mast. *Anaconda II* has Antarctic experience, having just completed the Rio De Janeiro Race through the "Roaring Forties" and around Cape Horn. The yacht comes fully equipped with the latest in navigational and electronic systems, including radar, satellite and terrestrial navigation, depth sounder, and access to remote computers. (It's probably too much to hope that they could keep the radio log in their computer . . .) The hams and mountaineers will use inflatable surf rescue boats to get to the rocky shore of Heard.

The choice of rigs and antennas for the Antarctic DXpedition presents a difficult problem. Sturdy, dependable, easy-to-repair radios are the order of the day. Another key to dependable operation involves taking several of the same radio. Then a malfunctioning radio can be cannibalized for parts if another fails.

The antennas and outside gear will take an even worse beating than the radios. The combination of freezing rains and high winds can destroy most antennas, so specially reinforced antennas are required of the day. Finding lubricants that won't freeze up for the antenna's rotors represents another necessity.

After the hams collect their equipment they must practice its assembly and repair. Each antenna and support system must be put together and taken apart again and again. What tools are needed? Can they be handled with gloves and mittens on? Exactly what hardware is needed for each operation? How many extra nuts and bolts should be taken? What do they do if piece X breaks? The size of the yacht limits the number of spare parts the DXpedition crew can take, so which are the most essential? These are the kinds of decisions which go into a well-planned DXpedition.

But even more important than the hardware is the "software"—the radio skills of the amateur operators. There are definite skills necessary for handling pileups, keeping the contact rate high, and giving everyone a fair chance at a contact. Weather conditions are going to be rough on Heard, and radio conditions might not be much better. Heard is a long, long way from any sizeable collection of amateurs. That means that Heard's signals will be relatively weak, and European, stateside, and Japanese signals will also be weak at Heard. It will take highly-skilled amateurs to keep the pileups under control.

We hope that the Heard Island DXpeditioners will avoid the kind of poor operation shown at the St. Peter and Paul Rocks (PYØ) this fall. There is simply no excuse for spreading out the callers over 100 kilohertz of the 20-meter phone band. Even the Clipperton Island DXpedition used only 75 kHz! There are many ways to spread out the callers without disrupting the entire 20-meter phone band. Non-DXers think poorly enough of the DX fraternity without this kind of bad manners. Perhaps it's time for a standard of DX conduct for DXpeditions. We'll have more to say about this in a future issue.

Meanwhile, the question of money continues. The mountaineering Heard Island trip may well cost $150,000 or more. Donations of equipment, supplies (including warm underwear), and cash have started the ball rolling. The expedition is taking film of the entire trip, to recoup some of their costs. An artist on the expedition team intends to sell paintings of the Heard Island landscape and penguins.

One major source of expedition funds is the amateur community. Both the Northern California DX Foundation (PO Box 2368, Stanford University CA 94305) and the International DX Foundation (PO Box 117, Manahawkin NJ 08050) have pledged $10,000 to the program. And both DX foundations are looking for new members and contributions to assist their work. The Australians organizing the amateur part of the trip are inviting amateurs and others to become associate members of the "Antarctic Adventure," at $30 (Australian). The VK6 DX Chasers are also selling DXpedition T-shirts at $9.50 (Australian). Contact them at Box 10, Perth 6005, Western Australia.

Meanwhile, Jim Smith continues to solicit funds and operators for his assault on Heard. You can send your contributions to Box 103, Norfolk Island, Australia.

Your contributions will help with the Heard Island DXpeditions and future trips to other rare spots.

Who will get to Heard first? Will there be anyone left to work for the second DXpedition? The best way to find out is to turn on your receiver and listen.

MAILING YOUR QSL CARD

If you do work Heard Island this winter, either VKØHI or VKØJS, you will want to get a QSL card confirming the contact. In the last two months we discussed how to design and fill out your QSL. This month we'll look at ways to get your card to the right place. I'll discuss these methods roughly in order from slowest to fastest.

The Bureaus

By far the easiest way to send your QSL to another amateur in another country is via the QSL bureau system. Every civilized country (and some that are not) has an incoming QSL bureau for the benefit of its amateurs. Incoming cards are sorted every so often and distributed to local amateurs.

Some of the bureaus are excellent. The Japanese and West Germans have especially top-notch bureaus. The smaller countries have less formal systems; in some cases, they are essentially nonexistent.

Sending your card to a DX station via the bureau is simply a matter of writing the DX station's call in the upper right corner of the back of the QSL and sending it to the address listed in the IARU information or the *Callbook*. If you have any number of cards going to the same country, the cost is a few cents a card.

An even easier system for ARRL members is the League's on-going DX QSL bureau. A membership label off *QST* and $1.00 per pound of QSLs (about 150) gets the cards off to the DX bureaus for less money (and probably faster) than any other service. Contact the ARRL for more information.

The chief complaint about the bureau method is speed. There isn't any. Three to four months is about as fast a turnaround as anyone can expect. A year or two is not unusual. With Russian QSLs (through the famous Box 88, Moscow), delays of 3-5 years are common and I have seen 10-15-year-old QSLs in packages direct from Box 88. Small wonder that it takes twenty years to get on the honor roll; it can take that long for a bureau card!

Commercial QSL Forwarding Services

There are other outfits which provide the same service as the League's outgoing QSL bureau, plus the added benefit of searching out QSL managers and faster QSL methods. These services advertise in most amateur-radio magazines.

The price per card runs about $0.10-.20, but service depends on the volume of cards and the expertise of the amateur running the operation. W3KT's service used to be the best, before Jesse passed away last year (see this column, September, 1982).

If you want to go this route, contact the operator and find out the number of cards per week he handles, how long the cards sit in his hands, how he arranges for return QSLs, and the calls of some hams who have used the service. Then follow up on this information before depending on the QSL forwarding service.

The same problem applies to this kind of service as to the League bureau system: It can take a long time. A well-run forwarding service can get cards to stateside QSL managers and back quite cheaply and rapidly. But DX QSLs usually go by sea mail and can be months in transit. There is another potential problem with the QSL forwarding services: Their success depends heavily on the skills of the manager. His knowledge of DX and QSLing can make the difference between cards on the wall and wasting your money.

Direct QSLs

Since DXers are an impatient lot, the preferred method involves sending a QSL of an important DX contact directly to the person handling the QSL chores. This person might be the actual DX operator himself or a QSL manager.

To send the card, you need the correct address. Obtaining this accurate address is one of the fine arts of DXing. The first place you look for this information is on the air. Listen to the DX station. Where does *he* say you should send the QSL? The horse's mouth is by far your best source of QSL information.

Next best are second-hand sources, such as DX nets, repeaters, and bulletins. Pulling information out of the bulletins is a time-consuming task, and errors abound. DX nets are a little better, but it helps to know who is providing the information, to help judge its reliability. DX repeaters offer the chance to talk to someone who has already received a card back from that DX station. Whatever method was successful once is worth another try.

If you don't want to spend your DXing time reading every bulletin and monitoring every DX net, you might consider subscribing to one of the DX QSL lists. Look for their ads in the magazines and bulletins. W6GO and K6HHD publish a QSL Manager List with more than 5000 calls. This list is updated monthly and costs $15.00 per year in the US. The address is PO Box 700, Rio Linda CA 95673.

Another possible source of DX address information is the *Callbook*. Some amateurs say they are "OK in any *Callbook*." The *Callbook* also lists QSL bureaus in the various DX countries. The *Callbook* is available at your local radio store or by mail.

Addressing the Envelope

You have finally located what you are sure is the "latest word," the "up-to-the-minute" QSL address. You could just write the address on the back of your card and mail it, but you would get an answer via the incoming QSL bureau or not at all. You probably want to send the card in an envelope, with a self-addressed, stamped envelope (SASE) enclosed.

Avoid the temptation of putting more than one card in an envelope. Say you worked Eric SMØAGD from several of his Pacific locations this past fall (see this column, August, 1982). Please don't put all the cards for SM3CXS (Eric's QSL Manager) into one envelope. Use a separate envelope for each QSL card. Or if you really can't afford to do that, at least send cards for each separate callsign in a separate envelope.

Mixing the calls or cards will only delay the response. Often, different people in different locations handle the cards for different calls, even though the QSL address is the same, as is the case with SM3CXS. If you mix several callsigns, the cards and your return envelope will go to one QSL manager, back to SM3CXS, and so on. Anywhere along the line your cards might get lost or separated from the return envelope. Make everyone's life easier, and speed your return QSL by sending each card in a separate outer envelope.

Should you put the callsign of the DX station on the outer envelope? An excellent question. If the card is going to an address in the States, Western Europe, or Japan, by all means do so. The first callsign on the address should be that of the DX station you worked, the second the call of the QSL manager: VP2ML via K1RH. This allows the QSL manager to sort the cards quickly.

On the other hand, I recommend *leaving off* the callsign on the envelope if the card is going to an African country, Eastern Europe, Turkey, or any other country where amateur radio is illegal or frowned upon. The reason is theft or danger to the DX amateur. Callsigns on the outer envelope may indicate money inside, so many of these envelopes never reach their intended destinations. In the case of Turkey, the DX amateur can run afoul of local authorities by receiving mail with a callsign on the envelope.

The best rule of thumb is, when in doubt, leave it off. And if you ever send personal mail to an active QSL manager, write in large letters, "Not a QSL" on the envelope! Otherwise, it may get thrown in with the QSLs to be answered "tomorrow."

When to Mail

We are all anxious to get our return QSL card, especially one confirming a rare QSO. So many of us rush right out the day we work the DX station and mail off the card. This is fine when the card is going directly to a DX resident in another country. But it is not necessarily the best time to send a QSL card for a DXpedition contact or to a QSL manager.

Many DXpeditioners handle their own QSLing. If you can still read them on the radio, they can't be home answering your QSL. Wait a while. In fact, most DXpeditions don't print the QSLs until they get home and know how many they need. It will often be a month or more before they even have any cards to fill out.

If you really jump the gun and send the card out while the DXpeditioner is still away from home, you can create some unneeded friction between the DXer and his local post office. When I returned from 10 days in the Galapagos, there were *6 bags* of QSLs waiting for me. On one day I received more mail than the rest of the local residents combined! The post office personnel thought I was running some sort of mail scheme and threatened to charge me a commercial rate and storage fees. And somewhere, buried in that tome of mail, were personal letters, bills, and checks. It took a solid day just to pull my personal mail out of the QSLs!

So give the DXer some time to get home, get some cards printed, and catch his breath, before overflowing his PO Box.

The same problem can happen when QSL managers get their log information via the mail. The logs might take weeks or months to get to the QSL manager, before he can look up the contact and answer your QSL.

Some QSL managers get around this by having regular schedules with the DX station. The manager reads the contact information, the DX station checks his log, and the QSO is confirmed. This system worked so well for me at VP2ML that one amateur received his QSL card less than 48 hours after the contact!

Enough about how to get your QSL card to the right place. It's the next step that's the important one anyway: getting the DX stations's QSL card back! Hang on until next month!

AWARDS

Bill Gosney KE7C
Micro-80, Inc.
2665 North Busby Road
Oak Harbor WA 98277

LABRE AWARD

The Worked All American Award has been instituted by LABRE (Liga de Amadores Brasileiros de Radio Emissao) to promote interest in the American area.

The WAA award will be issued to any licensed amateur station presenting proof of contact with forty-five (45) or more countries in the American area.

All applications should be sent to the Awards Manager, LABRE, PO Box 07/0004, Brasilia, Distrito Federal, Brasil, CEP 70.000.

Confirmations must be accompanied by a list of claimed countries to aid in checking. A log verified by the awards manager of the applicant's country league or association will be accepted instead of QSL cards. Logs may also be verified by two amateurs in the applicant's area.

All contacts must be made with licensed amateur stations operating in authorized amateur bands. Contacts must be made only with licensed and based amateur stations. Contacts with ships and aircraft *cannot* be counted.

All stations must be contacted from the same call areas where such areas exist, or from the same country in cases where there are no call areas. One exception is allowed to this rule. If a station moves from one call area to another, or from one country to another, all contacts must be made from within a radius of 150 miles from the initial location.

Contacts may be made over any period of years since November of 1945. Contacts may have been made under different call letters in the same call area (or country) if the license for all was the same.

Any altered or forged confirmations will result in permanent disqualification if observed by the WAA award advisory committee. A minimum readability of 3 (R3) must be recorded for phone and a minimum signal tone of 5 (S5) must be recorded for CW.

All applications must be forwarded with ten IRCs or equivalent for handling and postage and return of QSL cards by registered air mail.

All certificates will be consecutively numbered and an honor roll showing all those issued will be kept by the awards manager of LABRE.

The following list of countries in the American area (North and South America) is presented as a guide. Deleted countries will not be valid.

WAA Countries List

CE	Chile
CE	Easter Island
CE	Juan Fernandez
CE	San Felix
CM-CO	Cuba
CX	Uruguay
FG	Guadeloupe
FM	Martinique
FO8	French Polynesia
FO8X	Clipperton Island
FP	St. Pierre & Miquelon Islands
FS	Saint Martin
FY	French Guiana
HC	Equador
HC8	Galapagos Island
HH	Haiti
HI	Dominican Republic
HK	Colombia

YV	Venezuela
YV	Aves Island
ZF1	Cayman Island
ZP	Paraguay
6Y	Jamaica
8P	Barbados
8R	Guyana
9V	Trinidad & Tobago Islands

MARTINIQUE AWARD

The FM DX Group of Martinique is offering a certificate for QSOs with FM7 and FM0 stations. Three hundred points will earn the certificate, with scoring as follows: Contacts with an FM DX Group member count 10 points per QSO, FM0 contacts count 4 points each, and FM7 contacts count 2 points. A phone QSO is worth 1 point, RTTY or ASCII count for 2 points, and a CW contact is worth 3 points.

One point is given for a contact on 10, 15, or 20 meters, a contact on 160 or 80 meters is worth 2 points, and a QSO on any other frequency receives 3 points. One point also is added for each 3,000 miles distance from Martinique.

A minimum of 7 days is required between two QSOs with the same station, and 25 percent of the points must have been made in contact with an FM DX Group member.

Logs and a $5.00 money order should be sent to Gerard Souqui FM7BX, PO Box 152, 97202 Fort de France Cedex, Martinique.

W. VIRGINIA QSO PARTY

The West Virginia QSO Party, sponsored by the West Virginia State Amateur Radio Council, will be from 1700Z January 22 until 1700Z January 23. Single operator only. Exchange signal report, serial number, county (WV only), state, or country. WV stations multiply total by sum of WV counties, states, and countries worked. Others multiply QSO totals by WV counties worked. Multiply score by 1.5 if you run 200 Watts or less. Suggested frequencies Phone—10 kHz from lower edge of General subbands; CW—35 kHz from low ends; Novice—35 kHz from low ends. Repeater contacts permissible. Mail logs by February 11 to K8BS, 950 Gordon Road, Charleston WV 25303.

WISCONSIN SPECIAL EVENT

The Eau Claire, Wisconsin, ARC will operate K9EC/9 during the National 70-Meter Ski Jumping and Nordic Combined Championship on January 29 and 30 from 1400Z to 2300Z. Frequencies: CW—52 kHz up from bottom edge. Phone—3980, 7277, 14282, 21382, and 28620. For an 8½ x 11 certificate, send SASE to N9AIX, PO Box 201, Altoona WI 54720.

GROUNDHOG DAY

The Punxsutawney (Pennsylvania) Amateur Radio Club will operate on 14.290 and 7.230 from 9 am to 5 pm, January 30, 1983, in commemoration of Groundhog Day 1983. We will operate also on 7.230 on February 2, 1983 (Groundhog Day). This special-event station will operate from Gobblers Knob, the home of the Groundhog. Certificate for SASE and QSL card to Art Sweeney K3HWJ, RD #1, Box 371, Punxsutawney PA 15767.

GEORGIA'S 250TH BIRTHDAY

Savannah area amateurs will have a special-events operation in honor of the State of Georgia's and historical Savannah's 250th birthday. Operation will be February 12 and 13, 1500-2000Z on upper 25 kHz, all General phone, and 21.130 to 21.170 kHz Novice. QSOs on 2 meters 146.52 only. For special certificate, send QSL card with QSO number and large SASE to call of contact operator.

GOLDEN SHEARS AWARD

In honor of the 1983 Golden Shears

Sheep Shearing Contest in March, 1983, the members of New Zealand's Branch 46 in Wairarapa are offering an award for contacts made that month with their members.

To be eligible for the award on HF bands, ZL stations must have 10 points, VK stations must have 7 points, and DX stations need 5 points. Net contacts count toward the award.

On VHF, ZL2 stations need 15 points to qualify, other ZL stations have to get 7 points, and DX stations must have 3 points. Repeater QSOs count toward the award, but repeater/net contacts do not.

Scoring is as follows: Golden Shears President ZL2AHU is worth 3 points; club station ZL2OA, a YL operator, farming branch member, or mobile station within Wairarapa are worth 2 points each, and any other member is worth 1 point.

Except for crossband operation, any band/mode combination is allowed. However, only one contact per member is permitted unless the member is operating the club station or working mobile within Wairarapa. No QSLs are required for the award; send your application with $2.00 (NZ) or an equivalent International Money Order to Awards Manager, PO Box 860, Masterton, New Zealand. Entries must be received before August 31, 1983. All proceeds will go toward funding for an operating room for emergency situations.

NEW PRODUCTS

APOLLO X10 ANTENNA

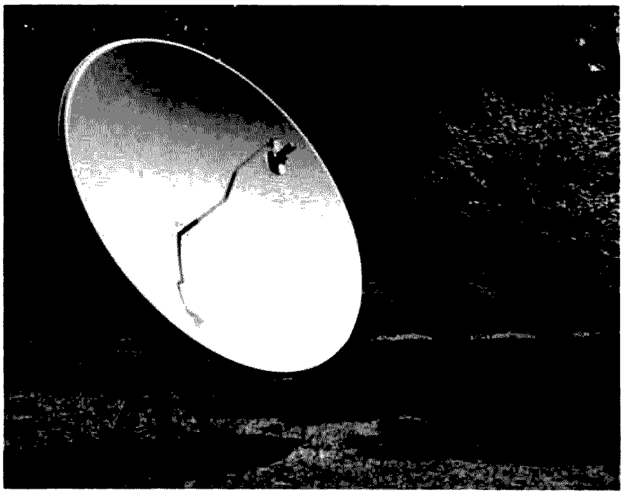
National Microtech, Inc., has just introduced its new Apollo X10 antenna, which utilizes a 10-foot, eight-segment, compression-molded fiberglass reflector. The reflector provides high strength-to-weight ratio and significantly reduces the size of the shipping container, thus providing savings in handling and shipping costs.

The X10 can be erected easily by two installers. The individual reflector segments are interchangeable and field-replaceable, utilizing indexing tabs for position and self-alignment.

The Apollo X10 delivers 40.1 dB gain at 3.95 GHz. Its textured front surface diffuses sunlight and reduces solar heating at the focal point, and the high-quality fiberglass material is impervious to salt, pollutants, and contaminants that may be encountered in coastal and industrial areas.

The center-mounted "button hook" prime feed provides accurate alignment with the focal point without the use of cables and other supporting gear. The LNA is located at the focal point while the rotor is placed at the rear of the dish, permitting rotation of the feed through 360 degrees of polarization by remote control.

For more information, contact *National Microtech, Inc., PO Drawer E, Grenada MS 38901.* Reader Service number 481.



National Microtech's Apollo X10 antenna.

Simpson's model 467E DMM.

UNITED STATES FREQUENCY ALLOCATION CHART

An updated "Varian United States Frequency Allocation Chart" is now available free of charge from Varian Associates Electron Device Group. The four-color chart includes radio, television, point-to-point, microwave, satellite communications, and millimeter wave frequency allocations. This 15" by 21" foldout wall chart features a ledger guide and is both color- and line-coded for easy reference.

Frequency allocations from 3 kHz to 300 GHz are divided into eight one-order-of-magnitude divisions. These divisions are color-coded to illustrate frequency uses of government exclusive, non-government only, and government and non-government shared frequencies. Line coding is then used for the demarcation of 31 specific frequency categories such as fixed satellite, radio navigation, land mobile, broadcasting, and meteorological satellite.

For further information, contact *Varian Associates, Electron Device Group Marketing, 301 Industrial Way, San Carlos CA 94070.* Reader Service number 488.

AZDEN INTRODUCES NEW PCS-4000

Japan Piezo Company, Ltd., and Amateur-Wholesale Electronics have announced their new PCS-4000 2-meter FM transceiver. Like its predecessors, the PCS-4000 utilizes keyboard frequency control, but many new features have been added, making this a truly unique radio.

Some of the features are 8-MHz coverage (142 to 149.995 MHz), extremely small size (2 inches high by 5½ inches wide by 6¾ inches deep), two banks of eight memories which can be scanned separately or together, capability for up to eight nonstandard repeater splits, and two priority channels. Other feaures include a full 16-key touchtone™ pad built in, multicolored display for easy function recognition, discriminator scan centering, repeater reverse button, and free/vacant scan mode selection with auto-resume.

For more information, contact *Amateur-Wholesale Electronics, Inc., 8817 SW 129 Terrace, Miami FL 33176; (303)-233-3631.* Reader Service number 483.

SIMPSON'S MODEL 467E LCD DMM

Simpson Electric Company has introduced a new hand-portable LCD digital multimeter. Model 467E joins the Simpson line of LCD hand-portable DMMs.

Features include peak hold to capture surge currents and voltages, a continuity mode to provide instant visual/audible checks for shorts and opens, and true rms capability for more significant measurements of non-sinusoidal waveforms over a wide frequency range. The 467E has 26 ranges to provide full ac/dc voltage, current, and resistance (including low-power Ohms) measurement capability.

Additional features include 0.1% dc V accuracy, high-voltage transient protection, a double fusing system, and color-coded front-panel graphics. Its size is a compact 2" × 5.6" × 4.6" and its weight is 1½ lbs.

For further information, contact *Simpson Electric Company, 853 Dundee Avenue, Elgin IL 60120; (312)-697-2260.* Reader Service number 486.

SUBMINIATURE CHANNEL SCANNER

Midian Electronics, Inc., has introduced a subminiature channel scanner. It features 6-channel capability on radios employing crystal high switching, 16-channel capability on radios using battery-line binary address, and 8-channel capability on radios using battery or ground switching. The scanner also has a priority channel scan capability as well as a three-second hold timer, manual advance, and an adjustable channel scan length.

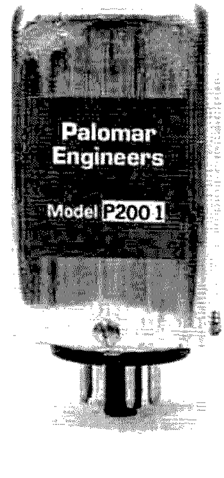
For further information, contact *Midian Electronics, Inc., 5907 E. Pima Street, Tucson AZ 85712; (602)-885-6883.* Reader Service number 487.

PLUG-IN DTMF DECODER

Palomar Engineers has announced a new single-digit decoder which is available for any of the 16 DTMF digits.

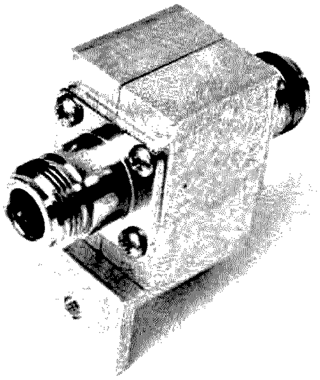
Replacing the firm's older model T2, the new P200 features improved temperature stability, high input impedance (200,000 Ohms), and a ½-Ampere SPDT output relay. It operates from 12 volts dc, signal levels from −25 to +5 dBm, and has a response time of 100 ms. The decoder plugs into a standard octal socket.

For further information, contact *Palomar Engineers, 1924F W. Mission Road, Escondido CA 92025; (714)-747-3343.*



Palomar Engineers' P200 DTMF decoder.

Icom's IC-290H transceiver.



PolyPhaser's new impulse suppressor.

ICOM'S IC-290H

Icom has announced the release of a new 2-meter multimode mobile transceiver, the IC-290H, featuring a powerful 25-Watt output and a highly sunlight-readable green readout in the same compact package as the IC-290A. Other features and styling of the IC-290H are the same as the previous model—the IC-290A. These include 5 memories for storing your most worked frequencies, a call channel to make your favorite frequency instantly available, 5-kHz FM tuning or 1-kHz/100-Hz tuning on SSB, FM/USB/LSB/CW modes, programmable offsets, a priority channel that monitors 2 frequencies, and scanning of memories or band.

For more information, contact *Icom America, Inc., 2112 116th Avenue NE, Bellevue WA 98004.*

ENCON PHOTOVOLTAIC PANELS

Encon, Inc., distributors of Solarex photovoltaic products for the Midwest, has introduced the new Solarex SX series of semicrystalline photovoltaic panels, using state-of-the-art technology.

Solarex semicrystalline cells offer unique advantages over earlier technology, including lower cost, increased packing efficiency, and higher power output compared with the traditional round single-crystal silicon cells. Semicrystalline cells are made by melting less-than-pure polycrystalline silicon, crystallizing it into rectangular "bricks," and then sawing the bricks into wafers to make rectangular cells. The cost reductions afforded by the new process promise to bring prices down from $100 per Watt to under $20 per Watt within the next few years.

Solarex suppplied the photovoltaic cells for the UoSAT (University of Surrey) OSCAR 9 satellite launched on October 6, 1981. OSCAR 9's four solar panels each contain 408 high-efficiency 2 cm × 2 cm cells. Each panel produces 27 Watts when fully illuminated. The Solarex system is designed to produce 18 Watts peak power and 8 Watts average power in orbit to charge the 14-volt nicad battery.

Encon, Inc., assembles complete photovoltaic power systems for emergency and primary communication applications, as well as residential and commercial packages. Interested amateurs are invited to contact *Encon, Inc., 27584 Schoolcraft, Livonia MI 48150.* Reader Service number 479.

ICOM'S IC-R70 GENERAL-COVERAGE RECEIVER

Icom has just announced its new professional general-coverage receiver, the IC-R70.

It is a full generation newer and features more functions than other less sophisticated general-coverage receivers on the market. Features include squelch on sideband, adjustable-width noise blanker, adjustable-speed agc, passband tuning as standard, and adjustable notch filter as standard.

Other convenient features are high-stability, synthesized tuning with tuning speeds, an optional AM/FM mode, variable CW-filter widths, dial lock, and two vfo's with data transfer. Also, the IC-R70 will operate transceive with the IC-720A, making an ideal combination for the serious DXer or CW buff.

For more information, contact *Icom America, Inc., 2112 116th Avenue NE, Bellevue WA 98004.*

POLYPHASER'S IMPULSE SUPPRESSORS

A new series of bulkhead-style impulse suppressors for coaxial lightning protection was recently introduced by PolyPhaser Corporation. This new IS-B50 series can easily replace older air-gap-type arrestors and can be mounted on up to 1/8"-thick bulkhead panels. These weatherproofed gas tube protectors are designed for repeaters, base stations, and TVROs to 1 GHz, with typical (N) 0.1 dB loss and 1.1-to-1 vswr. Their hefty 20-kA multi-strike and 50-nanosecond turn-on time make protection against most direct strikes possible. They come complete with weather washer and stainless steel hardware in both N and UHF fittings. A tower mounting kit is also available.

For further information, contact *PolyPhaser Corporation, 1500 West Wind Boulevard, Kissimmee FL 32741; (303)-396-1807.* Reader Service number 485.

DC POWER SUPPLY

Many mobile operators would like to be able to operate their mobile equipment at home on ac power mains. Tripp-Lite has just announced a product that meets that desire: a precision regulated dc supply that converts 120 V ac into 13.8 V dc. For example, CB radios, automobile tape players, tape recorders, high-power stereo systems, amateur radio equipment, linear amplifiers, and marine- or business-band radios can now be used at home.

The new low-cost power supply saves the user money, since it also eliminates the expense of having to buy ac equipment. It features a solid-state integrated circuit for precise regulation. A built-in filter ensures low-noise operation, and current-limiting electronic "foldback" is provided for automatic overcurrent protection. Other features include a heavy-duty power transformer for complete line isolation, a maximum ripple voltage of only 0.1 volts from zero to full load, an on/off switch and indicator light on the faceplate, and a UL-listed ac cord and plug (type SPT-2).

For more information, write *Tripp-Lite, 500 N. Orleans, Chicago IL 60610.* Reader Service number 484.

W9AV MORSE CODE TRANSLATOR FOR TRS-80 COLOR COMPUTER

J. C. Sprott W9AV announced some time ago his Morse-code programs for the TRS-80 Mod I/Mod III computers. Now, he has announced the availability of a Morse program in 16K extended color Basic for the TRS-80 color computer. It is believed that this program is the only Morse-code program available for sending and receiving Morse code by way of the computer's cassette port.

With 9 programmable memories of 240 characters each and a random-character "practice" mode, the translator program allows you to send and receive the code by merely plugging the computer cassette plugs directly into the transmitter key jack and the receiver phone jack. Morse code may then be sent at speeds of up to 60 words per minute and received at speeds of up to 30 words per minute.

For more information, write *Professor J. C. Sprott W9AV, 5002 Sheboygan, #207, Madison WI 53705.* Reader Service number 480.

Introducing the POWER PACKET™ from VoCom

An innovative new product that you can combine with your VoCom Power Amplifier to obtain the functions of the famous VoCom Power Pocket™ *using any handheld radio.*

AF POWER — 2 to 3 watts of road-noise-overcoming audio to your vehicle speaker or to external Packet Speaker™ (optional).

EASY HOOK-UP — Packet Bracket™ at bottom of Power Packet, provides place to clip almost any make or model handheld. Connects to handheld through pin jacks. Hooded light on Power Packet illuminates portable's front panel.

CHARGE POWER — 35 mA charge on receive, 400 mA when mic is keyed. Unless your handheld draws more than 400 mA, you can talk as long as you wish and the batteries will be at least as charged as when you started.

MIC PREAMP — adjustable; tie in your handheld directly without changing its mic input. Also makes Power Packet compatible with most standard mobile mics. Optional Packet Mic™ available.

Suggested retail $84.95. See your favorite amateur radio dealer.

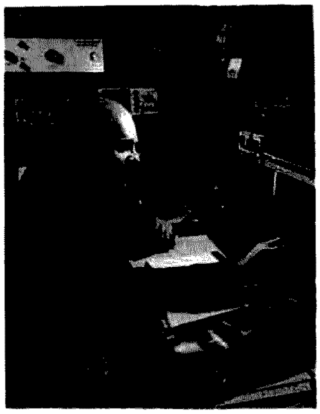
W2NSD/1 NEVER SAY DIE

editorial by Wayne Green



SABAH!

One of the reasons I got into publishing a ham magazine had to do with a rather serious character flaw on my part, one which dictated that whenever I found something really fun to do I was not satisfied until I shared my fun with others. Thus, when I found out what a blast playing with ham RTTY was, I just couldn't be satisfied until I got others to share my fun and enthusiasm. This got me started publishing a RTTY newsletter and gradually brought me to my present situation with *73* and some other magazines, mostly for enthusiasts.

Well, I'm in a tiny country called Sabah and you really should be here to be sharing my fun with me. The capital city is Kota Kinabalu, which few people have ever heard of. Much to my surprise, I arrived here from Brunei and found a surprisingly large city. The biggest hotel, the Hyatt, is 14 floors high; unlike in America, it has a 13th floor. Being not far from the equator, it is hot during the middle of the day. That's a nice time for a nap or to sit around a swimming pool writing postcards to those of less adventurous spirit.

Hassan 9M6MA met Sherry and me at the airport and drove us into town to the Hyatt. Later, he picked us up and drove us to his house, which is built on stilts over the water. Hassan expected me to be surprised, but I merely felt at home. When I was a teenager, my folks had a summer house built on stilts out near Floyd Bennet Airport in Brooklyn. We reached the house by walking over about a quarter mile of boardwalk; it was perhaps three feet wide and six feet over the mud flats and a couple of feet above the high tides. Some of the full moon tides would bring water up to the boardwalk. And I'll never forget the hurricane of 1938 when the extra high tides and storm washed away most of the boardwalks and some of the houses. We lost a dock and our rowboat, and my family just barely made it across the narrow walk as the storm hit. They had to use sticks to keep from being swept off the long walk. I missed out on that drama, being busy at home listening to 20 meters and the unusual propagation which the storm brought. No, Hassan's house wasn't a bit strange for me. We were joined by Ian 9M6MH, Mohamed 9M6MO, and his brother Ali, an SWL. We had quite an interesting little hamfest. None of them is really a DXer and they would prefer, as would most of the hams in rare spots around the world, to be able to get on the air and talk with people. They want, like every other person to whom English is a second language, to have a chance to improve their English. They'd like to get to know their fellow hams, yet every time they get on the air they are hounded by hams who "need" their remote country and have little respect for the interests of the DX operator. Many hams get very nasty if deprived of their "right" to a new country. This is the bane of most hams in rare spots and often drives them off the air. As long as we hams continue to support the ARRL Honor Roll, I'm afraid that this is going to be a problem. It isn't DXCC that's doing it, just the Honor Roll. Dare we call it a Dishonor Roll and anger the dozens of poor souls who have decided to devote their lives to keeping on top of this blight? What a waste of lives which might otherwise be productive.

A year ago, I wrote an editorial telling you that I was going to be going to Asia and asking you to come along. Well, you sure goofed this time. You not only missed out on consumer electronics shows in Tokyo, Taipei, Seoul, and Hong Kong, but also you missed a great ham convention in Bangkok, with about 150 hams coming in from all over the world, plus interesting visits to weird places such as Sarawak, Brunei, and Sabah. These places are really off the tourist trails, and yet they are each different and fascinating. Sarawak has but one active ham. What a spot for a DXpedition, eh? Well, there was one here recently which knocked off 10,000 contacts and still didn't cut down the pileups. I think you could DXpedition once a year for a week or so to Sarawak and be kept very busy. One of the main topics of discussion in Sarawak during my visit was a 25-foot crocodile which has been eating people. They'd flown in a medicine man to try to catch this bugger. . . somewhere up the Sarawak River. No, I didn't go for a swim in the river, which went right by our hotel.

There not being much of a tourist trade, there are very few stores aimed at tourists. There are hundreds upon hundreds of stores selling things for the local people, plus huge markets. I wandered around one bazaar and saw perhaps fifty stalls selling shoes. There were another fifty selling fruits, an acre or two selling vegetables, and so on. I can't tell you about all these things; you're just going to have to break loose and come with me on one of these trips and see everything for yourself. Oh, I've been taking slides by the hundreds, but even that can't really come close to an actual visit.

Kota Kinabalu is so far out in the sticks that neither McDonald's nor Kentucky Fried Chicken have found the place! Now, that's remote! Oh, they do have a McDonald's-like fast food store which serves hamburgers, fried chicken, sundaes, and even breakfasts. The prices are about the same as in the US.

These Asian tours are surprisingly inexpensive. Commerce Tours has been arranging them for several years and they have them down pat. They take you to the best of hotels. They include most of the breakfasts and a lot of dinners. If you eat only what is provided on the tour, you will put

QSL OF THE MONTH

This month's winning QSL from Roger Schultz NG6P is the result of a family effort. Roger's XYL, Diane, designed and stitched the original needlepoint for the card. Her work then was reproduced with a clarity that permits you to count the stitches, giving the impression of depth to the QSL card. The variety of stitches she used keeps the eye busy, and the border surrounding the design gives the card definition that many other cards lack.

To enter *73*'s QSL of the Month Contest, put your QSL card in an envelope with your choice of a book from *73*'s Radio Bookshop, and send it to *73*, Pine Street, Peterborough NH 03458, Attn: QSL of the Month. Entries without an envelope or book choice will not be considered.

on weight. The electronics shows are one of the best opportunities for you to find some little product to import and get your own mail-order business going. Or, if you are in the electronics business, this is a way to find an Asian partner to do some of your manufacturing for you. More and more firms, even smaller ones, have an Asian "plant" which is helping with circuit boards. Just one connection on a trip like this will pay for the trip several times over. The cost of the tour for the last three years has been around $2,500...which includes all airfares, first-class hotels, and a lot of the meals. That's one of the best tour bargains I've seen.

After the organized part of the tour, you can add some extra countries on at surprisingly little extra cost. The tour ended with the Hong Kong Electronics Show, but from there we went on to visit Singapore, Kuching, Bangkok, Bandar Seri Begawan, Kota Kinabalu, and Manila, all for about $500 extra in airfare.

There is going to be a big celebration in Brunei in a bit over a year when the country goes independent. The VS5 calls will change to a new prefix

LONG-DELAYED ECHOES

A former Los Alamos National Laboratory scientist has been honored by the Soviet Academy of Sciences for his explanation of long-delayed radio echoes. Robert W. Freyman received the Commemorative Medal of the Polar Geophysical Institute, the first time the Institute had honored anyone from outside the Soviet Union, according to the Oct. 7 issue of *Machine Design*.

Three- to 30-second delayed echoes of radio signals have been observed since 1927, and Freyman conducted a series of experiments aimed at solving the riddle of these echoes. He believes the signals are delayed because they are caught up in ducts of plasma in the solar wind surrounding the Earth. The wind blends with the Earth's magnetic field some 45,000 miles above the surface.

Radio-wave ducts in the blended plasma often stream toward the sun, Freyman says. "If radio signals encounter a duct, they are transported into space. They bounce back when the duct collapses, thus accounting for the delay."

The Soviets duplicated and confirmed Freyman's research. His work had special significance for the Soviets because they have pursued intensive investigations of long-delayed echoes since a 1979 multinational experiment produced the phenomenon over Soviet territory.—Thanks to reader Jacques M. Percourt F2YS/W2, Millbrook NY.

Well...I Can Dream, Can't I? by Bandel Linn K4PP

Unleash the TS-900

A rig like this deserves more room than 2 meters can give. Get on HF (including WARC bands) with this transverter.

After using my new TS-900 for a few months, I realized that with the exception of its dedicated 2-meter coverage, it had all the features found in the best HF transceivers. It seemed wasteful to keep it caged on 2 meters when all I needed was a transverter for operation on one of the HF bands. At about this same time, the three new WARC bands were announced and this furthered my desire to put the TS-900 on HF.

After considerable research on the subject of synthesizers and conversion techniques, I managed to design a transverter that is a definite engineering overkill. This box will take any switch-selected 1-MHz band from 0 to 30 MHz and upconvert it for receive to the 144-to-145-MHz range. In the transmit mode, the 2-meter transmit signal is translated down to the exact frequency as on receive.

Since I already had a 100-Watt broadband amplifier, I designed the unit for 5 Watts output. This is only 2 S-units below that of the popular 200-Watt PEP input transceivers and is certainly plenty of power for many contacts. If you want more power, I recommend either the 100-Watt-output transistor amplifier described in the ARRL *Handbook* or the unit described in Motorola's Engineering Bulletin EB63 (this is what I used).

What Can You Use It For?

With this transverter, I can operate anywhere in the HF range, transmit or receive, all modes. Unfortunately, the transmit output drops off below 1 MHz, but I don't need to talk to WCBS anyway. The transverter works with any multimode transceiver in the 10-Watt class and has a built-in attenuator to handle the full transmitter output power. There is a bypass relay to permit instantaneous operation on either HF or 2 meters without any cable switching. This also provides an OSCAR mode of operation that automatically switches between 2-meter transmit and 10-meter receive.

Since my TS-900 has FM capability, I have made extensive use of the transverter on 10-meter FM. The dual-vfo feature makes selection of any repeater offset possible. I have also made many contacts on 10-meter AM. Of course, I can operate CW and SSB on any of the 160- through 10-meter bands and listen to plenty of activity on commercial frequencies in between It is also great for MARS and CAP frequencies that are outside the normal overlap coverage of HF transceivers. If you are interested in BCB DX, the 100-Hz readout and super sensitivity are ideal. There is also plenty of interesting VLF activity in the 50-to-200-kHz region, including the 1750-meter band.

Construction

The design uses readily-available components. Most are available from *73* advertisers and my old faithful parts store, Radio Shack. The design has been successfully duplicated by 5 other locals and has worked every time. Total

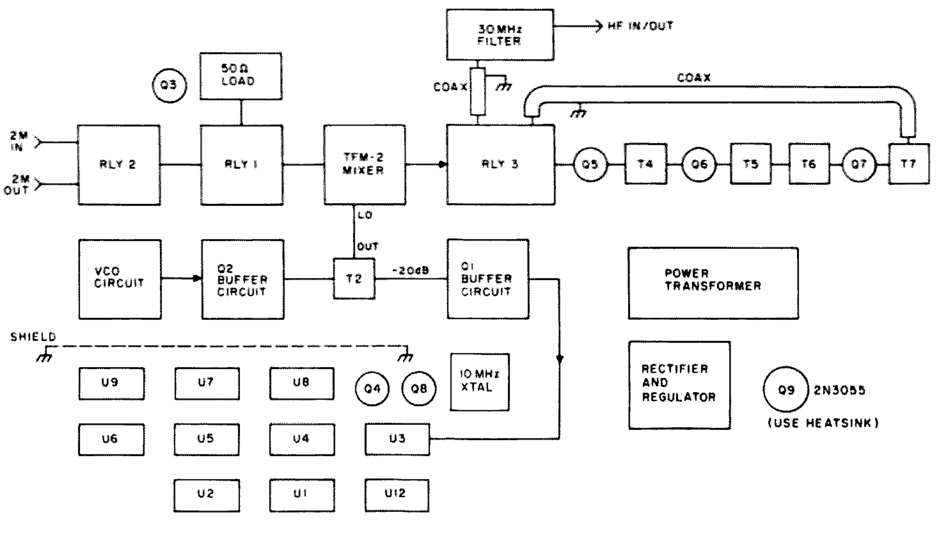

Fig. 1. Suggested layout of the HF transverter for 2-meter multi-modes.

cost with new parts should be under $150.

I didn't use a PCB layout since I was only building one unit, although the layout could be put on a PCB. If anyone is interested in such a project, I would be happy to give some recommendations on a layout.

My unit was built using the "dead-bug" technique and point-to-point wiring. ICs are mounted upside down on the copper side of a sheet of single-sided PCB, and all interconnections between ICs use #30 insulated bus wire. Where possible, components such as disc bypass capacitors are used as tie-points; one lead is soldered directly to the ground plane and the other, free end, supports other common circuit parts. To keep digital noise down, a 1000-pF disc is soldered to the Vcc lead of each IC. This connection along with direct soldering of the ground lead of each IC serves to secure the ICs.

I used a sheet of 8"×11" PCB that also serves as the top cover for an 8"×11" aluminum chassis. This provides excellent shielding and is really not an unattractive method. Fig. 1 shows a layout of various sections and critical components of the transverter. Fig. 2 provides details on winding the various transmission line transformers used in the transverter.

Theory of Operation

Fig. 3 shows the block diagram of the transverter. The key to the versatility of the unit is the synthesizer. It covers 115 to 144 MHz in 1-MHz steps and drives the bilateral mixer at about +7 dBm. As an example of the conversion scheme, to cover 17 to 18 MHz by tuning from 144 to 145 MHz, the synthesizer outputs a signal at 127 MHz (144−127=17).

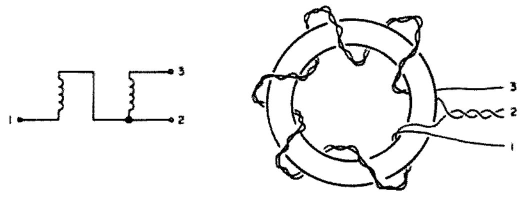
I chose to upconvert in 1-MHz segments and restrict the 2-meter coverage to the 144-to-145-MHz range for two reasons. It greatly simplifies the synthesizer design and also eliminates any problems in reading the frequencies on the transceiver dial. You simply ignore the 144 reading and mentally replace it with the MHz reading on the transverter thumbwheel dials. The other digits are the same.

Using the above example, 17.2366 MHz would read 144.2366 on the transceiver. A second benefit to tuning the 144-to-145-MHz range is that there are fewer strong repeaters operating there that might feed through the converter. However, this is not a serious problem since the design has over 80 dB of suppression of such signals.

In the receive mode, incoming signals pass through the transmit relay through a 30-MHz low-pass filter. They are mixed with the signal from the synthesizer in the balanced mixer. The output of the mixer at 2 meters passes through the T-R relay attenuator circuit and transverter bypass relay to the 2-meter transceiver. The overall loss through the converter is about 7 dB, so the typical 0.25-μV sensitivity of a multi-mode will be 0.5 μV on HF. This makes for a very sensitive HF receiver that can hear anything that the best HF transceiver can hear.

The scheme used for upconversion results in an overall receiver that is free from spurious responses without the need for elaborate multi-pole front-end filters. All of the newer-generation commercial and amateur equipment uses some form of VHF i-f range to eliminate problems with hard-to-suppress mixing products. This design has no spurious responses anywhere that can't be easily attenuated by the 30-MHz low-pass filter.

When the 2-meter transverter is keyed, the input from its external relay contacts activates two relays in the transverter. The first



Transformer	Turns	Core Material	Wire Size

Only one winding shown for clarity. Second winding is connected to first as indicated below.

Function	1st Winding	2nd Winding
Input	1	1
−20 dB	2	2
Ground	3	4
Output	4	no connection
51Ω	no connection	3

Fig. 2. Coil-winding specifications. All cores are mix Q1 from Palomar Engineers, Box 455, Escondido CA 92025. All windings are made with two pairs of wire twisted five crests per inch.

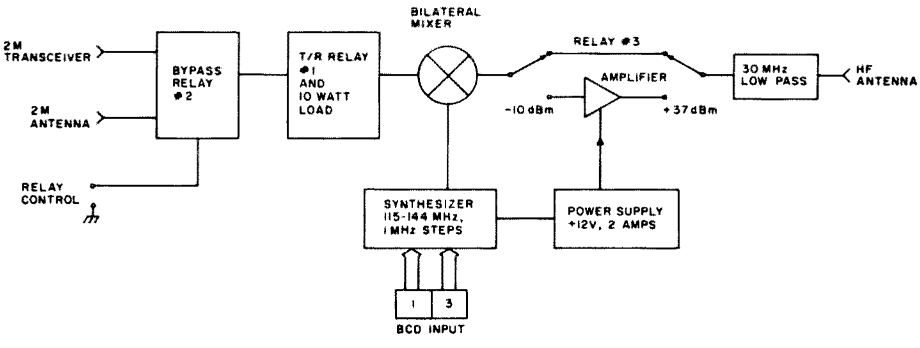

Fig. 3. HF transverter block diagram.

relay switches the 2-meter input into a 10-Watt load and also allows the mixer to sample a small portion of this signal for mixing with the synthesizer signal. The other relay switches the input/output of the mixer to the power amplifier chain. The output of the mixer is about −10 dBm PEP. This is amplified to the 5-Watt level by 3 broadband amplifiers in the power amplifier. Other than the 30-MHz filter, no low-pass filters are used for transmit since harmonics are at least −30 dBc and I felt that at this power level this was more than enough.

OSCAR Mode

In this mode, the 2-meter transceiver is automatically bypassed to the 2-meter antenna whenever the transceiver is keyed. The dual-vfo feature of most multimodes makes OSCAR operation extremely simple. The only disadvantage is that you cannot monitor your own signals, but I have never found this to be a serious disadvantage.

Options

If you don't want or need transmit capability, you can delete the associated relays and power amplifier circuits. The 30-MHz low-pass filter should connect directly from the HF antenna to the mixer. If you delete the 2-meter transfer relay and load, make sure you don't ever key the 2-meter transceiver while connected, or the mixer will be damaged. With the power amplifier eliminated, you can use a much smaller and cheaper power transformer —see parts list for details.

Circuit Operation

Fig. 4 shows the schematic of the transverter. At first glance, the circuit may look complicated, but it is really quite simple and straightforward. The voltage con-

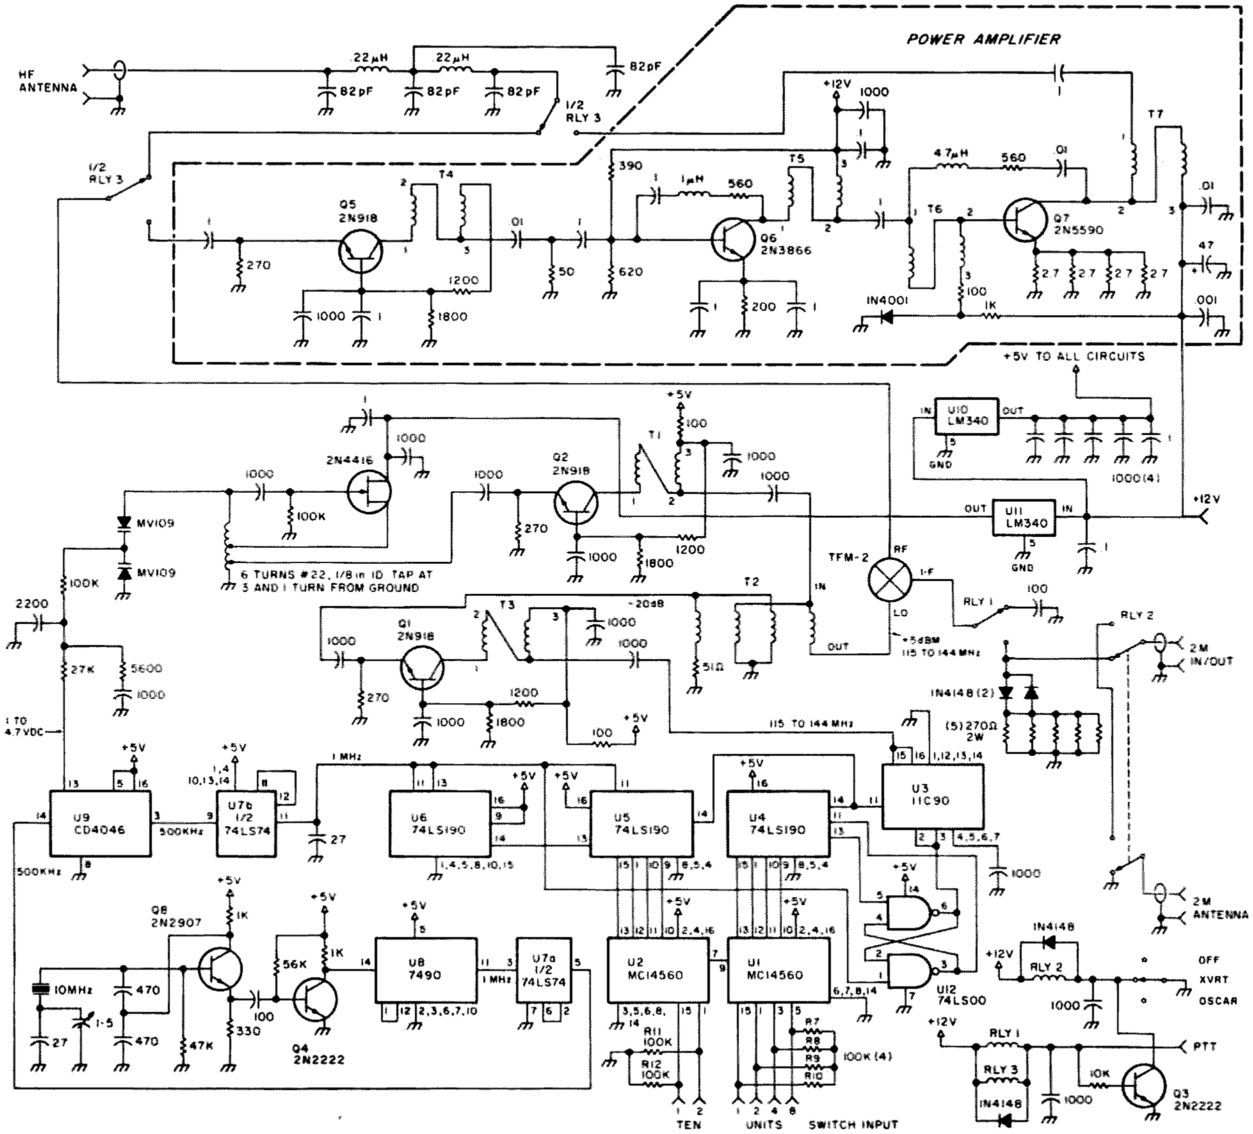

Fig. 4. HF transverter schematic diagram. All resistors 1/4-Watt, 10%, specified in Ohms unless otherwise noted. All capacitors are in pF, disc ceramic, 50-volt minimum unless noted. Pull-up resistors on BCD inputs are connected to ground or +5 volts, depending on use of positive or negative switch logic. Relay 1—Radio Shack 275-003; relays 2 and 3—275-214.

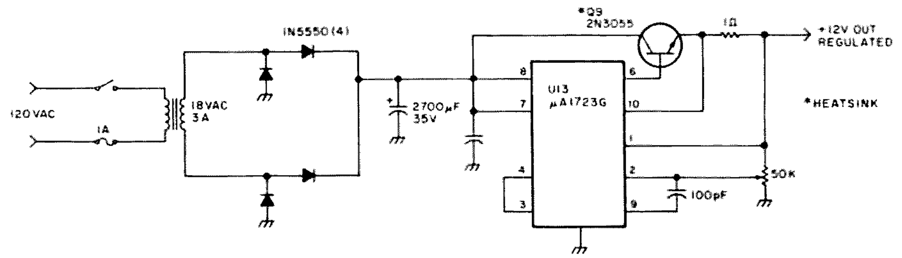

Fig. 5. Regulated +12-volt supply. Power transformer is Radio Shack 273-1514. For receive-only, substitute 273-1515.

trolled oscillator (vco) tunes from 114 to 145 MHz with a 1-to-4.8-V-dc control voltage. There are two common-base isolation amplifiers—one feeds the vco to the balanced mixer and the other, coupled through a 20-dB coupler, buffers the output to the divider chain. Since the desired frequency steps are in 1-MHz increments, the 10-MHz crystal-controlled reference is divided by 10 to produce 1 MHz for one input of the CD4046 frequency/phase detector. The other input of the CD4046 comes from the output of the divider chain that produces 1 MHz when the loop is locked. The phase detector output is filtered and frequency-compensated to deliver a dc control to the vco.

As an example of the divider operation, for a synthesizer frequency of 115 MHz, which corresponds to a range of 29-30 MHz, the thumbwheels are set to 29. The two MC14560 ICs (U1 and U2) are adders that add a constant 66 to the values produced by the thumbwheel input. This sets the first 74LS190 upcounter (U4) to 95. The second 74LS190 (U5) is hard-wired to divide by 8 so the resulting divide ratio is 895 (read left to right). Since this is an upcounter divider, the actual divide ratio is 115: (100−89)+(10−5). I used upcounters instead of downcounters due to the "backwards" relationship of thumbwheel setting to synthesizer frequency and to simplify design of the adders.

The 11C90 divider IC actually divides by 11 for a portion of the rf input period and by 10 for the remainder. Its operation is controlled by the 74LS00 and the output of the first 74L190 dividers.

The phase detector actually operates at 500 kHz, but since both the 1-MHz reference and the variable divider output have identical divide-by-2 circuits, the vco is stepped in 1-MHz increments. I had to operate the CD4046 phase detector at 500 kHz since 1 MHz was too high in frequency for reliable operation with a 5-volt supply. Also notice that the reference frequency is divided from a 10-MHz crystal. This was done for stability reasons since any error or drift at 10 MHz is multiplied by a factor of 14. This also gives reduced noise output of the synthesizer since noise of the reference is multiplied by a smaller amount than with a 1-MHz crystal. A conventional regulated +12-volt supply (Fig. 5) powers the power amplifier and 5-volt regulator for the logic. The circuit is capable of 3 Amps and can be simplified if transmit operation is not needed.

I would recommend using a smaller power transformer, as shown in the parts list, and replacing the 723 regulator and 2N3055 regulator by a simple 3-terminal +12-volt regulator. This will be more than adequate to power the remaining circuitry. Note that for receive-only operation you don't really need RLY 1, and if you don't mind disconnecting cables, you also can eliminate the 2-meter bypass relay, RLY 2, and all associated circuitry.

The 5-Watt power amplifier chain is a collection of various circuits that I've used in the past and I don't take any credit for designing them. There is little that can go wrong if normal rf construction practices are followed. Be sure to use short leads on all components, and keep inputs and outputs separated and physically in a straight line. Refer to Fig. 2 for details on winding the broadband transformers. Also note that the 2N5590 final transistors will require some form of small heat sink attached to the mounting screw. I used a 3" × 3" square of .060" aluminum mounted on the underside of the PCB used for the power amplifier chain.

Putting It on the Air

After all the circuits have been wired and checked out and are working, the best way to tell what kind of a job you did is to put it on the air. The only adjustment is to adjust the vco coil for about 4.8 V dc when set to 00 MHz (144 MHz actual).

If you run into any unsolvable problems, drop me a line with an SASE and I will try to help. ■

Four-Tone Audio Oscillator: A Potent Troubleshooter

For any test that requires a tone, this oscillator does the job. It can also be computer-controlled.

Howard F. Batie W7BBX
12002 Cheviot Drive
Herndon VA 22070

The versatile four-tone audio sine-wave oscillator described here can be used to test originate/answer modems, to generate RTTY tones, for two-tone testing of SSB transmitters, for aligning tone decoders, for analyzing audio filters and discriminators, and for many other audio applications. Its TTL-compatible controls even allow it to operate under software control by virtually any

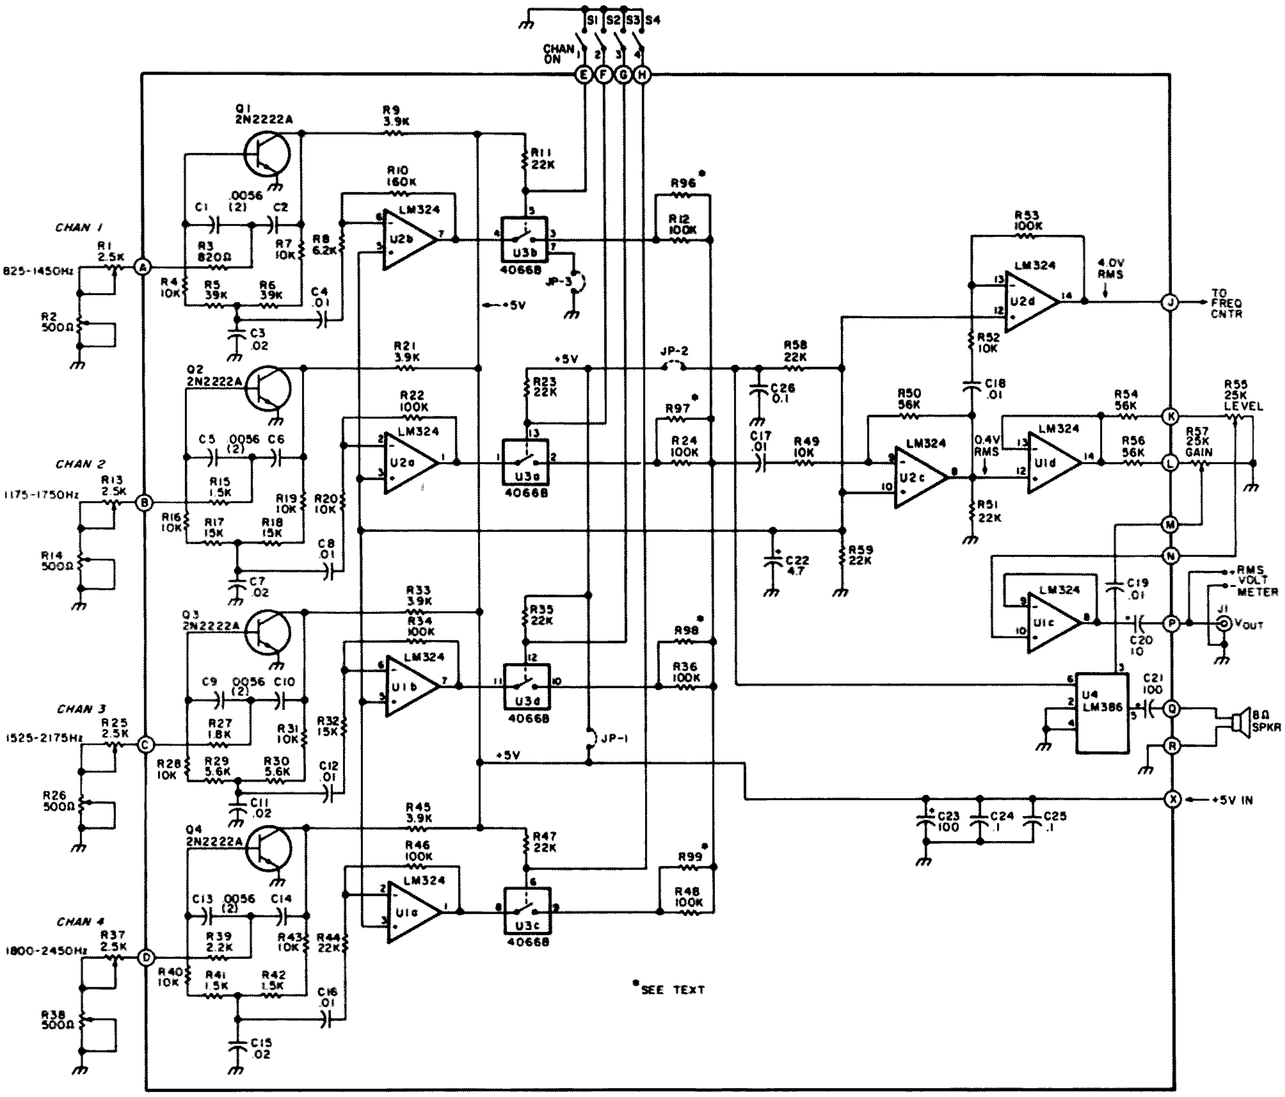

Fig. 1. Oscillator PC board schematic. (©1981, HFB Enterprises)

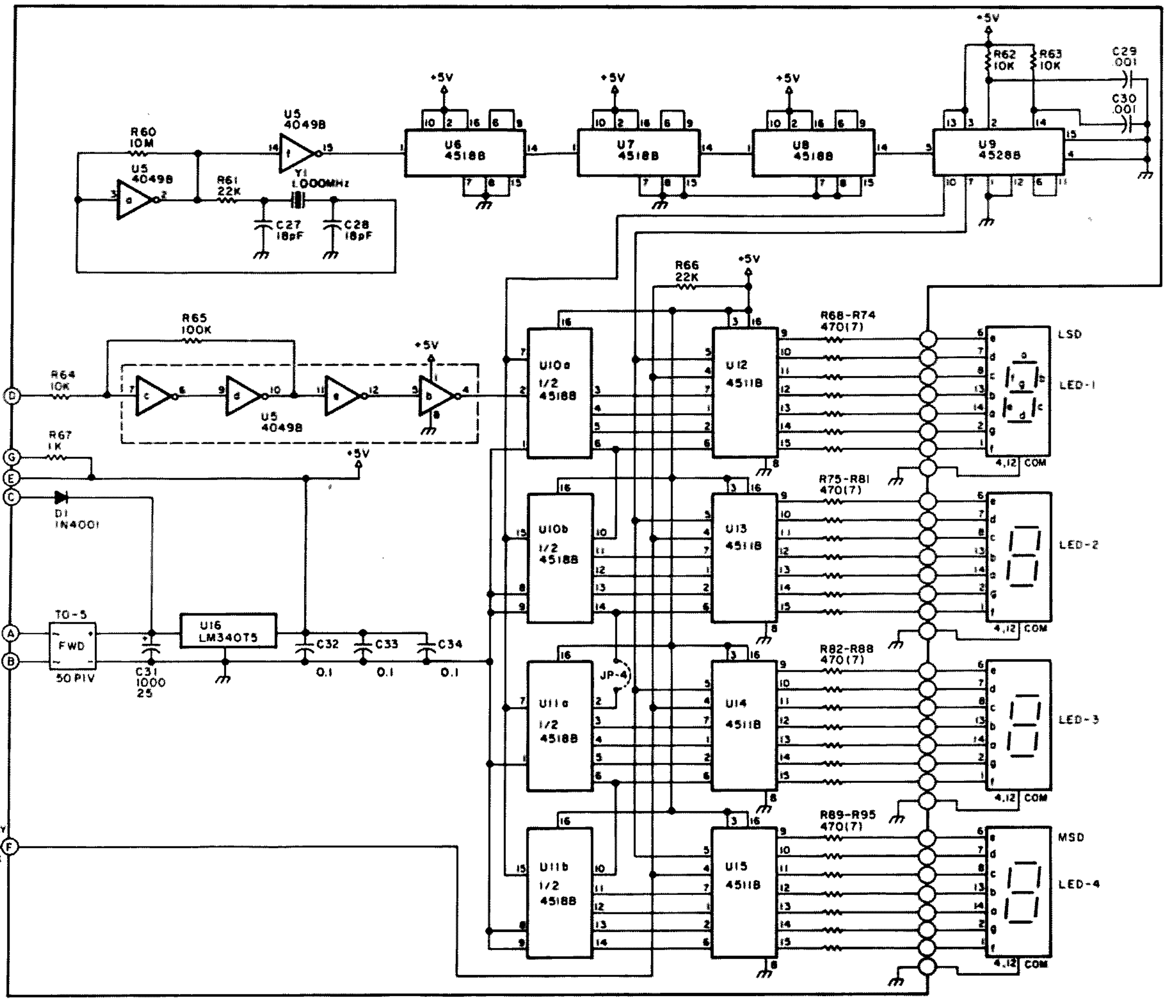

Fig. 2. Frequency counter PC board schematic. (©1981, HFB Enterprises)

computer. Also featured is an integral, direct-reading, 4-digit frequency counter with on-board regulated supply and an on-board audio amplifier. Individual signal-output level and audio-volume controls are provided, and the output signal can supply more than 1 volt rms to a 50-Ohm resistive load.

Low-power CMOS digital integrated circuits and operational amplifiers are used to keep current consumption to a minimum. The four-tone oscillator and frequency counter each are assembled on a 3" × 4" printed circuit board. About 300 mA is required from a 9-15-volt-dc supply when the frequency counter display is on; provisions also are included to blank the display to reduce cur-

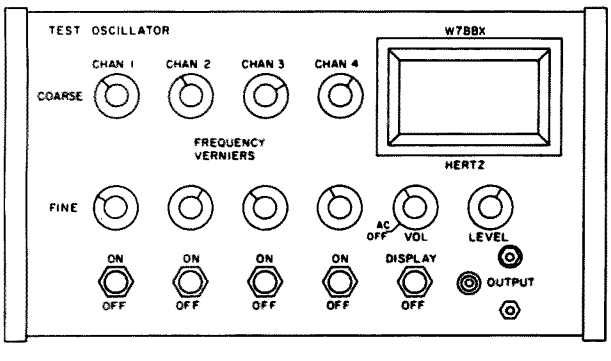

Fig. 3. Front-panel layout.

rent requirements to about 40 mA when operating from a battery.

Sine-Wave Oscillators

Four continuously-running twin-tee oscillators (Q1-Q4) generate the sine-wave audio signals. The frequency of oscillation of Q1 is determined by C1-C3 and R1-R7; by comparing these values with the Q2-Q4 oscillators, you can see how changing only resistors R4-R7 alters the center frequency of oscillation. The value of R3 will determine the amount of variation around the center frequency permitted by the coarse- and fine-frequency vernier controls, R1 and R2.

The output of the twin-tee oscillator is taken from the top of C3 and capacitively coupled by C4 to buffer/amplifier U2b. Gain of this amplifier is determined by the ratio of R10 divided by R8. The gain of each of the four buffer/amplifiers is slightly different to accommodate the amplitude drop of the twin-tee oscillators as frequency decreases. Therefore, with the component values shown, pins 1 and 7 of both U1 and U2 will furnish approximately the same output amplitude. The outputs of the four buffer/amplifiers are fed to individual CMOS analog switches (U3). When the control pin 5 of U3b is high (logic 1), pins 3 and 4 are effectively tied together; however, when pin 5 is taken low (logic 0), pins 3 and 4 are effectively open. The resistance between pins 3 and 4 is about 300 Ohms when pin 5 is high, and several hundred megohms when pin 5 is grounded.

With a logic 1 signal on the control pin, either analog or digital signals may be passed through the gate; furthermore, because the gate is bidirectional (effectively only a resistance), either pin 3 or 4 may be used as the input and the other as the output. Each of the four sections of U3 is individually controlled by S1-S4. If desired, S1-S4 may be replaced with a quad latch which can be driven from a computer parallel output port.

The four outputs from the solid-state switch, U3, are then resistively mixed by R12, R24, R36, and R48 and capacitively coupled by C17 to an audio mixer, U2c. The amplitude of each of the four signal lines is equalized by placing an appropriate value resistor (R96-R99) in parallel with R12, R24, R36, or R48. The gain of mixer U2c is set by the ratio of R50 divided by R49. With the components shown, pin 8 of U2c provides 1.08 volts rms to U1d, an isolation buffer with unity gain. U1d drives two output circuits, the audio amplifier, U4, and the output signal buffer, U1c.

The input to the audio amplifier is fed from a resistive voltage divider R56-R57. Neither value is critical; R56 could be replaced by a jumper wire or a 100k-Ohm resistor, and R57 can be any audio taper

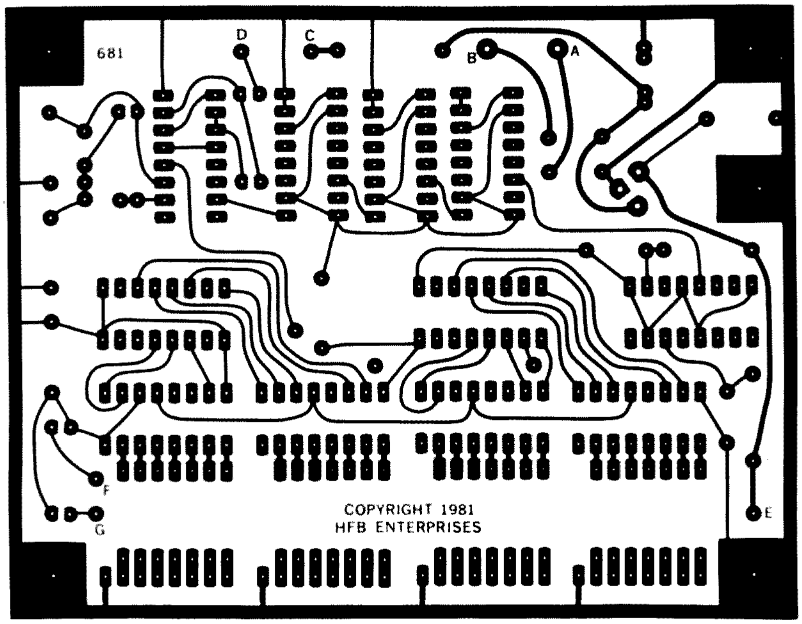

Fig. 7(a). Frequency counter PC board (top).

3. The frequency counter PC board is mounted above the oscillator PC board on 2" bolts up through the chassis floor.

The oscillator PC board is installed first and wired to the panel controls. Don't make the hookup leads so short that you can't lift it off the bolts if required. At this point, you'll have two wires from the oscillator board unconnected, the +5-volt lead (X) and the audio input to the frequency counter (J). With a speaker connected to the rear jack, connect the wire from Point X to a 5-volt power supply and check the operation of each audio channel individually and for mixing of two or more channels. With an ac voltmeter connected to the front-panel terminal posts, check the output level at the center frequency of each of the four audio channels. If the mid-range voltage differs significantly, the channels with lower voltage can be raised to that of the highest-voltage channel by installing an appropriate value resistor at R96-R99.

Disconnect the power supply. Now wire the LED display for the frequency counter; I used a perfboard with 90°-angle IC sockets and color-coded wires soldered to the appropriate LED pins. The same color-code wire should be soldered to the same-numbered pin on each IC socket. Mount the LED display perfboard on 3" bolts so that the LED display is positioned in the center behind the bezel. Lastly, mount the frequency counter PC board on top of the oscillator board and connect to the LED display perfboard, transformer, and oscillator board.

pot with a value of from 10k to 100k Ohms. R56 is included here only to limit the input level to U4 so that it is not accidentally overdriven. The output of U4 is coupled through C21 directly to an external speaker with an impedance of 8 Ohms or greater. For convenience, you may want to mount the speaker inside the test-oscillator cabinet.

The output test signal buffer, U1c, provides final isolation and can, with the components shown, provide a maximum output of 0.5 volts rms (no load), 0.43 volts rms to a 600-Ohm load, or 0.32 volts rms to a 50-Ohm resistive load. If required, additional output can be gained by reducing the value of R54.

In addition to driving U1d, the U2c audio is capacitively coupled through C18 to a separate buffer/amplifier, U2d. The gain of this section is purposely high both to ensure CMOS transition in the following stage and to clip the audio signal peaks to provide some preconditioning prior to being fed to the frequency counter input.

Frequency Counter

The audio signal from point J on the oscillator board is fed to point D on the frequency counter board (see Fig. 2). U5c and U5d form a Schmitt trigger whose output is further conditioned by the CMOS transition characteristics of U5e and U5b. The output of U5b is a digital stream of TTL/CMOS-compatible pulses with approximately a 50% duty cycle; the pulse repetition rate (digital "frequency") of the stream is the same as the analog frequency of the input to U5c.

A 1-MHz oscillator is formed by U5a and U5f. This signal is divided by 100 in each of U6, U7, and U8 to yield a 1-Hz gating signal for the frequency counter. The number of pulses in one second from U5b pin 4 is counted by U10 and U11, decoded by U12-U15, and displayed by LED1 through LED4. At the end of the 1-second counting interval, U9 resets the U10/U11 counters to zero while retaining the previous 1-second interval's count in the U12-U15 latches for a continuous, flicker-free display. Grounding point F will blank the display to conserve power. Point G of the frequency counter board is connected to the lower right-hand decimal point of the least significant LED display to serve as a power-on pilot light.

Power for the entire unit can be supplied either from the ac line or an external battery. Polarity protection diode D1 is included to prevent accidental damage caused by incorrectly connecting the battery. The +5-volt regulator, U16, provides power for both the frequency counter and, through point E of Fig. 2 to point X of Fig. 1, the oscillator board.

Construction

The four-tone oscillator of Fig. 1 is constructed on a 3" × 4" single-sided PC board, and the frequency counter of Fig. 2 is on a 3" × 4" double-sided board. A Ten-Tec MW-8 cabinet (8"W × 4¼"H × 6"D) was selected to allow enough panel room for the frequency verniers, control switches, and frequency counter display bezel. The front panel is shown in Fig.

Applications

The Radio Amateur's Handbook contains an excellent section on the test-

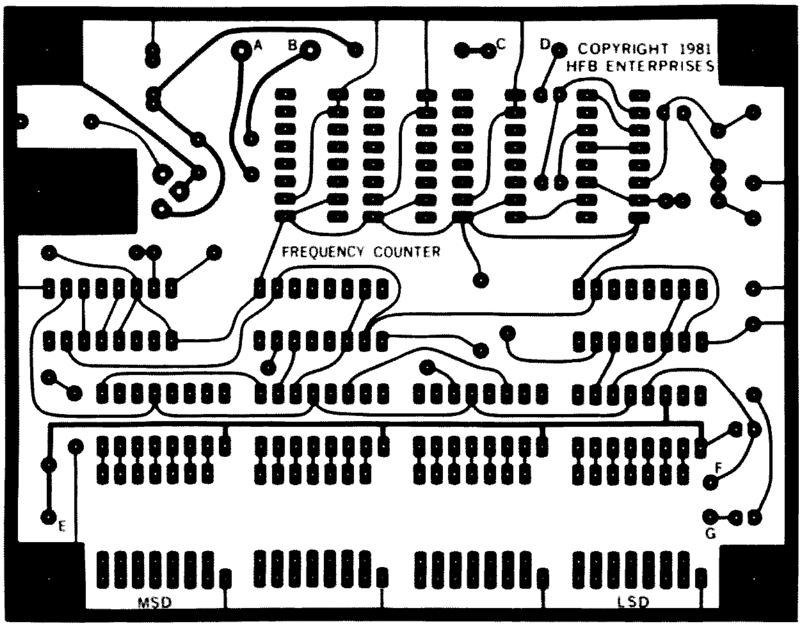

Fig. 7(b). Frequency counter PC board (bottom).

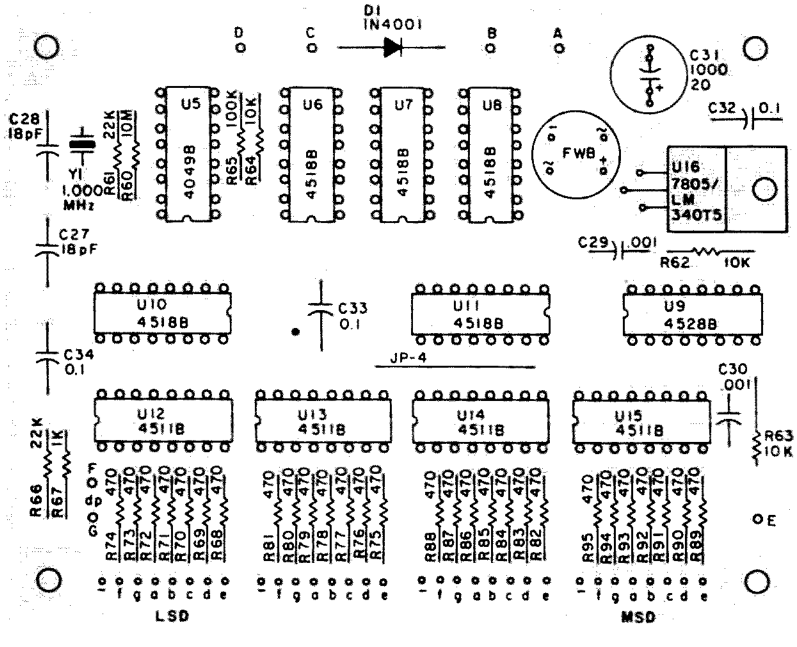

Fig. 8. Frequency counter board component layout.

ing of SSB transmitters using a two-tone test signal to approximate a speech signal. If you have an oscilloscope or modulation display/monitor, the transmitter-modulation waveform can easily be monitored and the modulation level set to get the maximum PEP (peak envelope power) without distortion or "flat-topping" of the audio signal. The four-tone audio oscillator described here is an excellent piece of gear to use for these tests since from two to four independent sine waves can be mixed to form a composite audio test signal. The four-tone oscillator output may be connected directly to the transmitter microphone input since it has a capacitively-coupled output.

Another excellent application is the testing of acoustically-coupled telephone modems for use with computers. The four audio channels can be set individually to the frequencies of the desired mark-space tone pairs for both the originate and answer modes. When connected to the modem inputs, each tone can be enabled separately to fully test the modem without having to reset the oscillator frequencies between mark and space. Simply set each audio-channel frequency vernier to the desired frequency and switch back and forth using S1-S4.

The same procedure can easily be used to test RTTY demodulators. In this case, only two audio channels would normally be required because of the simplex nature of RTTY; the same audio-tone pairs are used in both the transmit and receive directions. In both the computer modem and RTTY cases, you may want to replace S1 and S2 with a single-pole double-throw switch with the center grounded, one side of the SPDT switch going to point E on the oscillator PC board, and the other side of the switch going to point F. With this arrangement, toggling the single switch would then alternate between the preset mark and space tones.

If you're going to use the four-tone oscillator for aligning audio filters or analyzing their audio passbands, you'll appreciate the relatively constant output amplitude across the vernier range of the oscillator. Although there may be some slight variation in amplitude, it can easily be corrected by R55 if a high-impedance (10k Ohms-per-volt or greater) ac VOM or VTVM is used at the audio-oscillator output terminals between point P and ground on the oscillator PC board. With a separate ac VOM or VTVM, you can monitor the audio-filter output voltage easily as a function of the constant-voltage input as the oscillator is swept through the audio range.

You may also want to alter the frequency-determining components of one or more of the twin-tee oscillators for your own particular application. Tone

decoders in the subaudible range and a significantly increased maximum frequency for audio-amplifier testing are only two that come to mind. The twin-tee oscillator design is very versatile in its range as long as both sides of the capacitance and resistance arms remain equal (C1 = C2 and R4 + R5 = R6 + R7). This also ensures minimum distortion of the sine wave. The resistance and capacitance to ground (R1 + R2 + R3 and C3) also will play a part in determining both the center frequency of the oscillator and the range over which it can be tuned. An oscilloscope connected to the oscillator output will be a big help in selecting the right components for minimum distortion.

Conclusion

This handy piece of equipment is in near-constant use to test and align other on-going projects. Since the frequency counter reading will be accurate when only one tone is present; tones may be set individually to within 1 Hertz and then mixed to form a composite test signal. One easy-to-include option for additional flexibility is the insertion of an SPDT switch between the oscillator board point J and frequency counter board point D. This allows counting the frequency of an external signal and direct display of its last four digits. ■

APRIL 29, 30, MAY 1, 1983

Hara Arena and Exhibition Center — Dayton, Ohio

Meet your amateur radio friends from all over the world at the internationally famous Dayton HAMVENTION.

Seating will be limited for Grand Banquet and Entertainment on Saturday evening so please make reservations early. Banquet speaker is Bill Leonard, W2SKE, former president of CBS News.

If you have registered within the last 3 years you will receive a brochure in late February. If not write Box 44, Dayton, OH 45401.

Nominations are requested for Radio Amateur of the Year and Special Achievement Awards. Nomination forms are available from Awards Chairman, Box 44, Dayton, OH 45401.

For special motel rates and reservations write to Hamvention Housing, 1406 Third National Bldg., Dayton, OH 45402.
NO RESERVATIONS WILL BE ACCEPTED BY TELEPHONE.
All other inquiries write Box 44, Dayton, OH 45401 or phone (513) 849-1720.

Admission: $7.00 in advance, $9.00 at door. (Valid for all 3 days)
Banquet: $14 in advance, $16 at door.
Flea Market Space: $15 in advance. (Valid for both days)

Make checks payable to Dayton HAMVENTION, Box 2205, Dayton, OH 45401.

Bring your family and enjoy a great weekend in Dayton. Sponsored by the Dayton Amateur Radio Association, Inc.

A Breakthrough
for Amateur and Commercial Repeater Users.

DIVERSITY RECEPTION—the ability to add a second receiver to your repeater system—can now be a reality for even the small user. The Pegasus VS-2 will allow your repeater to "listen" to two receivers simultaneously and to noiselessly switch between receivers as often as necessary to adjust for fading and nulls. This is particularly useful for repeaters that wish to provide coverage for hand held users or where receiver desense is a problem. You supply the second receiver & RF link and the VS-2 does the rest. Complete instructions and diagrams included with the VS-2.

Superman's Repeater Control System

This simple system offers four independent on/off outputs. Just duck into any phone booth to use it.

In order to comply with FCC regulations, all repeaters must have incorporated within them a means of control. If the machine is located in the control operator's shack, the control system can be as simple as the switch on the repeater itself. However, the repeater is usually remotely located well away from the operator's reach, so other means of control must be contrived.

Many types of control systems are in use today, from some as simple as a wire pair to exotic UHF links with tones used as the command medium. The disadvantage of this system is, of course, cost. A control receiver and antenna is needed at the site and every control operator must have a control transmitter which usually isn't as portable as the HT on your belt.

However, let's brighten up the picture a bit. There is a way using resources at hand. The Bell System and friends have provided us with a remarkable communications system which is available to anyone (for a nominal fee) almost anywhere.

There have been many control systems developed using the telephone, and here is one that's inexpensive, easy to build with readily-available parts, and has some very interesting features. For example, this system needs no direct connection to the phone line, has four independent on/off controlled outputs, uses TTL devices needing only a +5-volt supply, and control can be accomplished from any phone, anywhere, at no cost to the user. Now you must admit, this is pretty neat. Fig. 1 shows how we go about it.

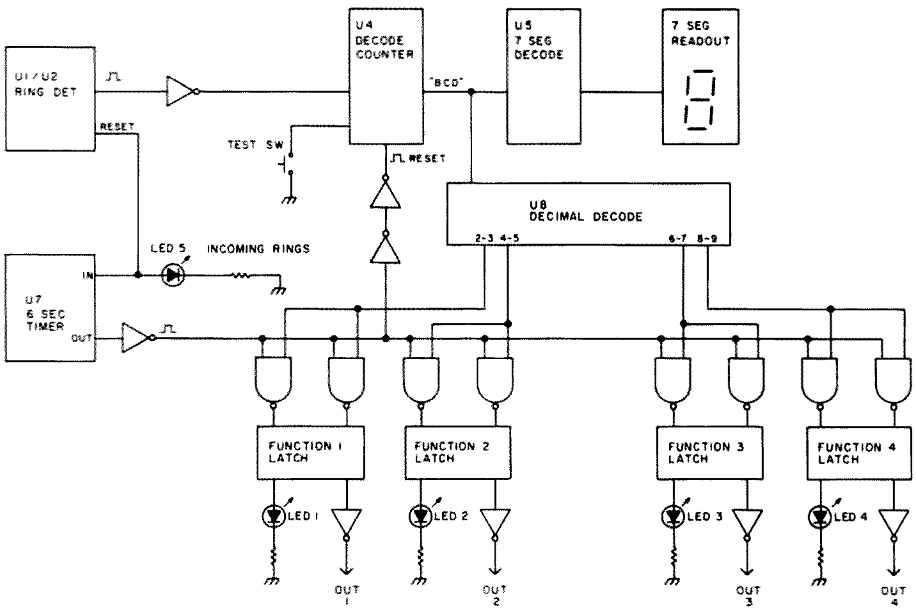

Fig. 1. Wireless-wire remote control system block diagram.

Theory of Operation

In operation, the circuit monitors the phone line, waiting for an incoming ring. When received, the ring is sensed by inductive

coupling to the telephone's internal transformer. The ring-detector circuit converts the rings into a series of logic pulses, one for each ring. These pulses are then counted and stored by a 7490 decade counter. The output from the counter is decoded twice, first by a seven-segment decoder which drives a front-panel readout indicating the status of the counter, and again by a BCD-to-decimal decoder which provides an output on an individual line with each successive pulse.

Another job for the ring detector is to reset a timer circuit with each ring. This timer (a good ol' 555) will fire every six seconds, provided it does not receive a reset pulse from the ring detector. This prevents the timer from firing during a series of incoming rings.

The output lines from the decimal decoder are inverted and connected to one input of individual NAND gates. The remaining gate inputs are paralleled and receive an inverted positive pulse from the timer.

Now we can see that as rings are received, one of the eight used outputs from the 7442, U8, when inverted, will put a high level on its particular output gate. It will remain there until another ring pulse is received, advancing the counter. Or, if the ring stops, the timer is allowed to time out and upon firing, an output will be generated from one of the output gates which will either set or reset the particular output latch.

The latch outputs are isolated from the board outputs by NAND gates connected as inverters. This prevents any noise picked up by the output wiring from getting back into the latches to cause headaches.

Circuit Description

Perhaps the most interesting circuit in the system is the ring detector. It is unique because it needs no direct connection to the phone company wiring.

The whole show starts with a simple tape-recorder pickup coil available at Radio Shack for a few dollars. It comes with cord, plug, and a handy suction cup for sticking it to the telephone.

The coil is connected to the board where it feeds a 741 op amp, U1, wired in a differential configuration (see Fig. 2). This mode reduces the effect of stray rf or noise pickup to a minimum. The output of the op amp feeds Q1, a PNP transistor that converts the output voltage to a level handy to drive the 7413 Schmitt trigger, U2. R1 and C1 serve as a low-pass filter to smooth out the 20-Hz ring voltage, providing U2 with a slowly dropping voltage during the duration of the ring. Diodes D1 through D3 are 1N914 or equivalent.

The Schmitt trigger acts as a NAND gate and provides hysteresis of the input signal. Its output is a clean TTL level of either a high (+5 volts) during a ring or a low (0 volts) between rings. This point is monitored by LED 5, located on the card front, to visually indicate the incoming rings. A pushbutton test switch, S1, also is mounted on the card and is connected to one of U2's inputs to simulate incoming rings for local control and test purposes. The positive pulse from U2 is coupled to the base of Q2 through limiting resistor R2. The incom-

Number of rings	Command
2	Function 1 on
3	Function 1 off
4	Function 2 on
5	Function 2 off
6	Function 3 on
7	Function 3 off
8	Function 4 on
9	Function 4 off

Table 1. Operating code.

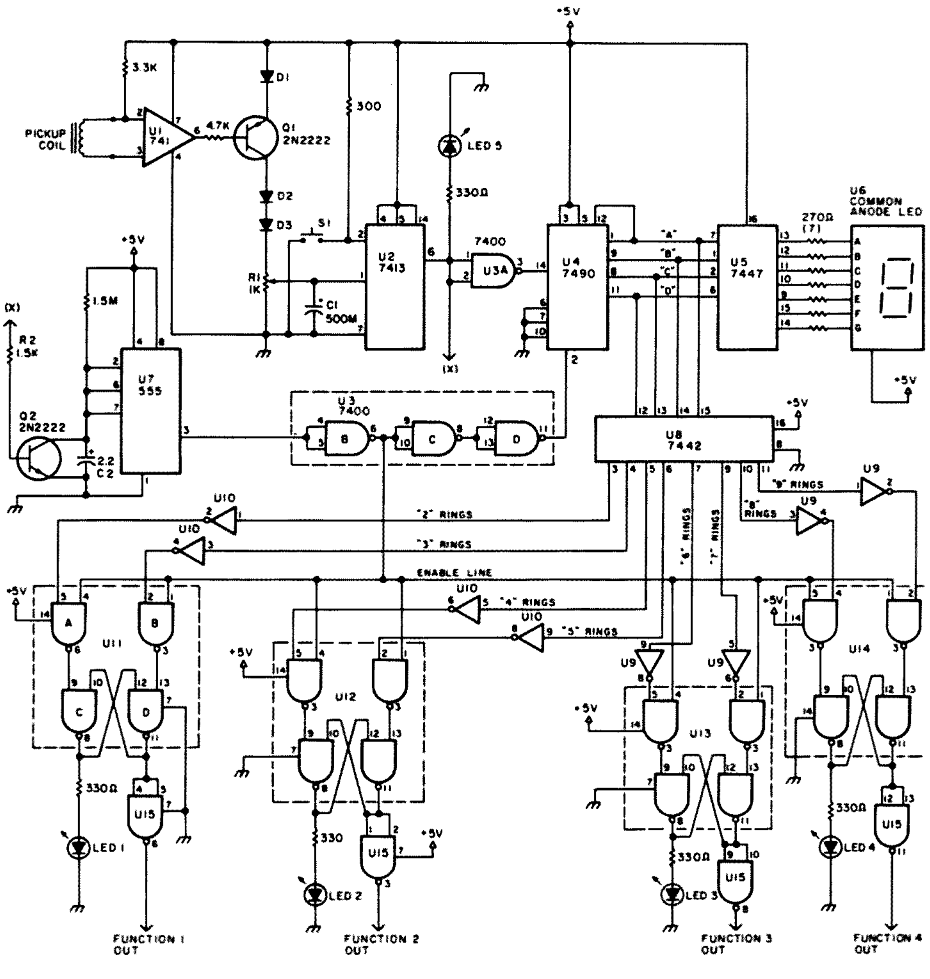

Fig. 2. Schematic diagram of system.

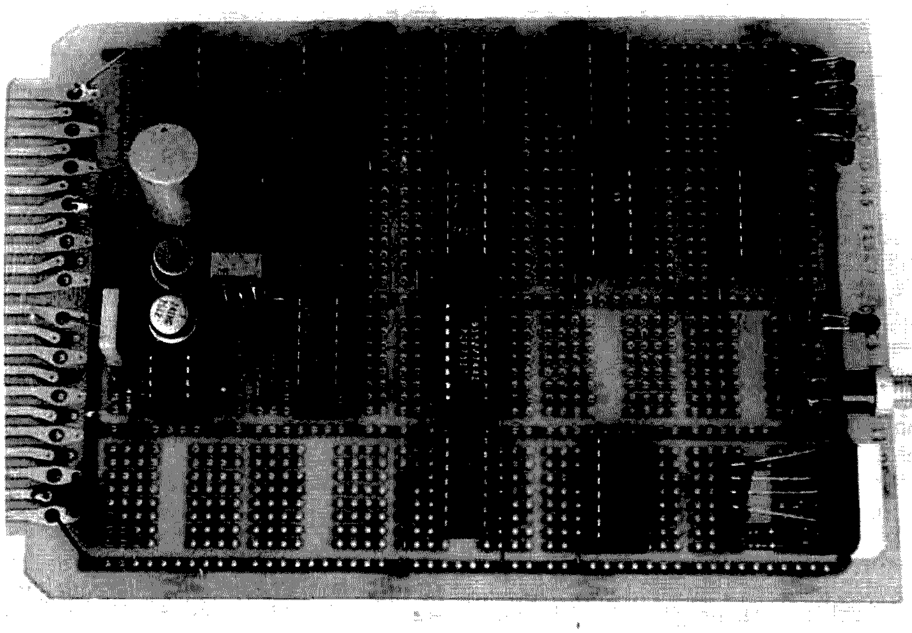

Photo A. Top view of board.

ing ring turns on Q2, effectively shorting out timing capacitor C2 and resetting the timer. The same pulse from U2 is inverted by U3A and steps the counter, U4.

The counter's output, a BCD total of rings received since the last timer firing, is decoded simultaneously by U5 and U8. U5, a seven-segment decoder, and its display, U6, are not actually needed for operation of the board and are there for creature convenience only. It's important to see the status of the counter when testing, and the seven-segment LED will indicate when the timer executes the command by displaying the return to zero.

U8, on the other hand, is essential to the operation of the system for it converts the counter output to a low level on one of its output lines. In operation, decimal outputs 0 and 1 are not used, leaving lines 2 through 9 to do the work.

Now that we've covered the ring detector, timer, and decoders, let's take a look at the schematic, Fig. 2, and follow a command through the steering gates and output latch.

Let's assume the phone starts ringing. The first ring resets the timer and advances the counter to BCD 1. U5 and U6 decode and display the 1 count on the LED. The second ring enters and also resets the timer and advances the counter to BCD 2. At this time, the caller hangs up the phone, the ringing stops, and the timer, which is not being reset by the incoming rings, fires after about 6 seconds. Its output, inverted by U3B, puts a positive pulse on one input of each steering gate. Remember, now, that there are two rings racked up in the counter so the LED displays 2 and only the decimal 2 lead (pin 3) from U8 is low. This signal is inverted and applied to U11A, pin 5. The level here is high and sets the gate up to pass the command pulse from the timer. When the timer fires, the high-going pulse is applied to the other input of U11A, pin 4. During the duration of the timer pulse, both inputs are high, so the output on pin 6 goes low, setting the RS-configured sections of U11C and D. When set, pin 8 of U11 goes high turning on LED 1, a front-panel indicator of latch 1 status. The complementary output from the latch, pin 11, is inverted by U15 and provides an isolated logic-high output at edge-connector channel 1 output which can be used to activate whatever function 1 interface you choose.

If the phone is allowed to ring 3 times, decimal 3 output of U8 (pin 4), after inversion, will activate gate U11B. U11B's output is connected to the reset side of the function 1 latch thereby turning off function 1 when the timer fires.

Note that the timer pulse from U3B continues through U3C and D and is used to reset the counter back to zero. The double inversion is necessary to de-

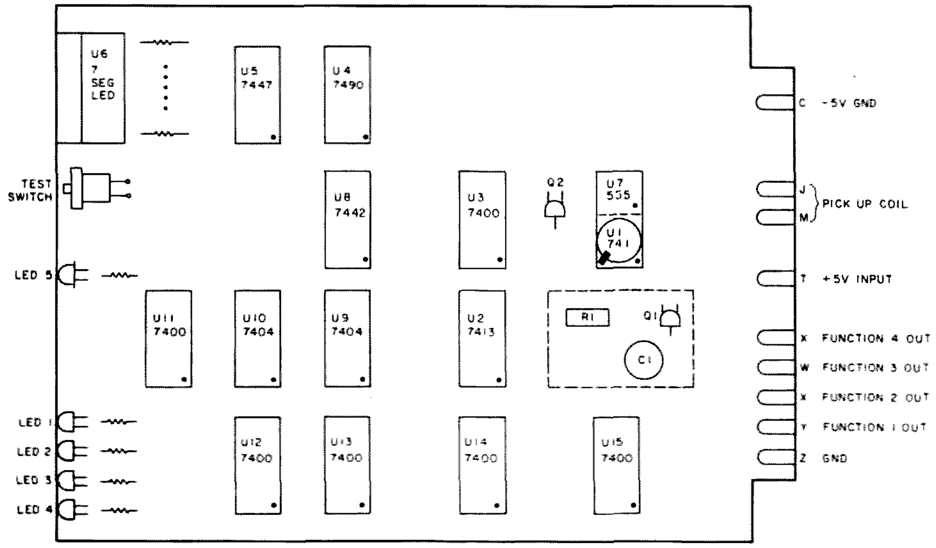

Fig. 3. Parts placement.

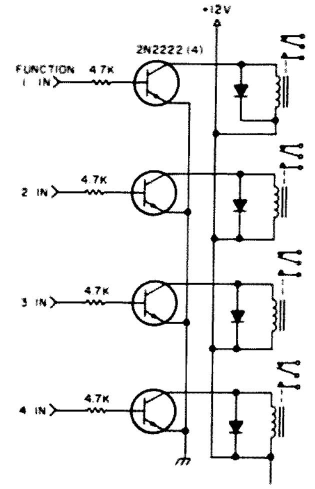

Fig. 4. Relay-control interface circuit.

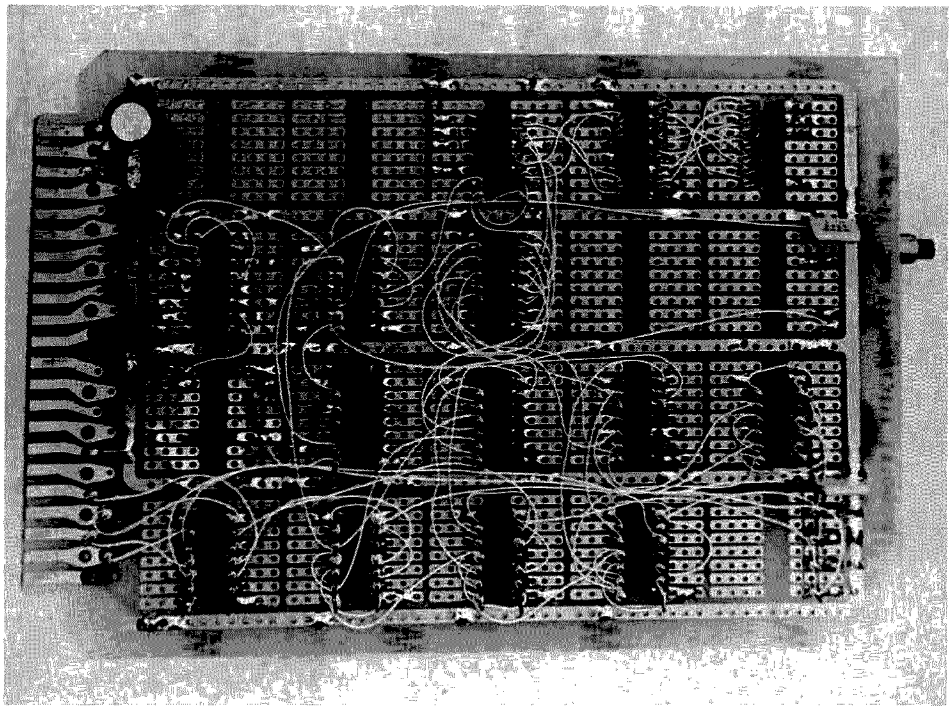

Photo B. Bottom view of board.

lay the reset pulse to the counter to ensure that the command is executed before the count is canceled.

Operation of the three additional function latches is identical except for the amount of rings necessary to select the particular command lines. Table 1 shows the operating code.

Construction

My board was wire-wrapped on a standard 4½"×6" glass board with edge connector attached. I used a board manufactured by Douglas Electronics, 718 Marina Blvd., San Leandro CA 94577. Made of excellent quality material, including gold-plated edge connections, it has room for 20 16-pin DIPs and a convenient power bus arrangement so no Vcc line runs will be over an inch. Designated type 11-DE-6, it's a bit expensive at $16.00, but you get what you pay for.

Parts placement is not critical. My layout is shown in Fig. 3. As with all TTL projects, be sure to scatter a few 0.1-μF disc caps around the power bus to soak up the spikes.

Interfacing

The TTL levels can be used directly from the controller if your operating system is TTL-compatible. If not, some type of interface will be required.

I use a simple relay control circuit, Fig. 4. The relays and accompanying driver transistors are located on another card placed alongside of the controller in the card cage. Some types of miniature reed relays can be driven directly by TTL levels, and if you're really a purist and desire to switch the repeater primary power, a solid-state relay driven directly by TTL can be used.

Phone Requirements

It's obvious that this type of system has some drawbacks. It cannot differentiate between control-operator calls and wrong numbers. We've had no problems in the time this system has been in use, but there are a few things to keep in mind when ordering your phone. Get an unlisted number for obvious reasons and ask for a new number, one that has never been issued. Imagine the frustration possible if you get a reissue of a number used by recently defunct "Pietro's Pizza Palace." It's also good practice not to use the same phone line for autopatch and control because the control operator who tries to dump a nuisance patch will get greeted by a frustrating busy signal.

Wrap-Up

Although the inductive ring detector is new, this system has been in use for about five years with excellent results. Previously, we used a direct connection to the phone line which also worked well. However, we worried what Ma Bell would say if she knew.

When powering the controller, use a well-regulated supply good for about an Amp to be safe. Another good idea is to float the input to the regulator on a battery, as momentary power interruptions quickly upset the output latches.

Hookup and Adjustment

Pot R1 must be set to put the input to the Schmitt trigger just above the trigger level, about 1.5 volts measured at pin 1 of U2. Action of the ring detector can be adjusted by bringing the pickup close to the body of a transformer-type soldering gun while triggering it. You may be surprised at how far the pickup can be from the gun and still get reliable action. Attach the pickup to the phone case using the suction cup. Exact location can be determined by moving it around the phone while it is ringing and watching the "incoming ring" LED.

What to control is left up to your imagination. Some of the control functions we use are: function 1—repeater on-off; function 2—autopatch on-off; function 3—brag-tape disable; and function 4—squelch adjust.

So get your wire-wrapper out and get going. When you're done, you will have a versatile and reliable addition to your system.

Thanks go out to Jim W3BBS for his encouragement and Joe N3JD for the photography. ■

Up and Coming: Direct-Broadcast Satellites

The only thing not up in the air in this business is the satellites, so this budding technology is not just pie in the sky.

Ask three different people about direct-broadcast satellites (DBS) and you are likely to get three different answers. First, there are the entrepreneurs. To them, DBS is the golden opportunity of the 80s, a chance to make big bucks. Next, there are the local broadcasters and cable TV operators. They consider television direct from the satellite to be a threat, especially since the spacecasters will have limited local responsibility. Finally, there are the engineers. The slide-rule and soldering-iron set consider direct broadcasting to a be a noble challenge requiring powerful transmitters and low-cost yet sensitive receivers.

What does DBS mean to you? That depends. But don't go on to the next article in hopes that DBS will go away. Why not find out a bit more as *73* enters its second year of satellite TV coverage?

Before going too far, it is only proper that we acknowledge that a form of satellite broadcasting already exists. But any substantial similarity between the current TVRO craze and DBS ends there. Gone is the need for a 10-foot dish in the backyard and a $1000 receiver in the living room. Central to the concept of 1990s-style DBS is low cost and small size. That way, spacecasters hope to attract an audience as broad as the country itself.

Just about the only aspect of DBS not up in the air are the satellites themselves. Even though this is an industry in its infancy and today's plans could very well line tomorrow's wastebasket, several things can be said with a good deal of certainty.

The direct-broadcast service will use geosynchronous satellites, meaning that like today's TVRO birds, they'll appear fixed in the sky. All that a US viewer will have to do is point his or her dish to the appropriate point on the southern horizon. No tracking or movement of the antenna will be required once it is locked onto the selected satellite.

We also know that the DBS signals will be in the 11-12-GHz region, where frequencies have been allocated for such purposes. This will require new technology since relatively little is available in the way of low-cost consumer electronics at those frequencies. The choice of the 12-GHz "Ku" band almost makes the present day 4-GHz satellite-TV gear look like it is meant for dc!

A third "fact" is that DBS offerings are expected to supplement rather than replace the current system of local broadcasting and cable television. You might want to wait a while before climbing up on the roof to take down the old VHF-UHF aerial.

Pie in the Sky

Imagine a business with 20 million customers, each of whom spends $500 for a receiver and shells out an additional $10 per month for the privilege of unscrambling signals. It doesn't take a calculator to figure out that DBS equals big money, probably in the billions of dollars per year. And, as you might expect, a lot of people are already looking for a piece of the action. Participants in the DBS free-for-all range from big guns like RCA, CBS, and Western Union to a handful of basement tinkerers bent on building a better mousetrap, receiver style. Someplace in the middle are outfits like Advance, Inc., and Home Broadcast Television, hardly household names—at least not yet.

Money-making methods vary. Firms like RCA and Western Union, already experienced in satellite technology, would like to act as

DBS: IS THERE A DISH IN YOUR FUTURE?

Shortly after this article was written the FCC granted approval to Satellite Television Corporation's plan to construct a direct-broadcast satellite-television system.

Satellite Television, a subsidiary of Communications Satellite Corporation, was the first firm to apply for spacecasting rights and is the first firm to get approval. The STC proposal, which calls for four satellites, suggests that three channels of scrambled programming could be activated by 1986.

Eight other applications for direct-broadcasting service were scheduled for FCC action by the end of 1982. A September 24, 1982, *Wall Street Journal* report goes on to say that no DBS hopeful will receive orbital or frequency assignments until after a hemispheric conference in mid-1983.

US Home Earth-Station Sales

Backyard Terminals				
Unit Sales (thousands)	25	75	120	5
Installed Base (thousands)	41	161	506	611
Revenues ($ millions)	175	375	360	15
Rooftop Terminals				
Unit Sales (thousands)	—	216	2000	5000
Installed Base (thousands)	—	290	3582	15582
Revenue ($ millions)	—	650	1420	2270

(Source: International Resource Development, Inc.)

Fig. 1. International Resource Development, Inc., shows a growing market for "backyard" TVRO terminals through the mid-1980s. By the end of the decade, the "rooftop" terminals will begin to predominate.

carriers, leasing satellite transponders to broadcasters. Other groups, like United States Satellite Broadcasting Co., will need to seek out technical partners to complement their skill in producing programs and selling advertising. A third segment of DBS hopefuls would like to act in a manner similar to cable-TV suppliers. They would purchase most of their programming and generate income from rent on decoder boxes or royalties paid by local distributors.

The markets for direct broadcasting are as varied as the potential suppliers. CBS has requested three channels. One slot would serve as a feed to local CBS stations and individuals unable to receive local broadcasts. The remaining two channels are needed to distribute programming directed at businesses like cable TV and movie theaters. CBS signals would, in all likelihood, be scrambled to prevent unauthorized reception.

Other proposals, like the one from National Christian Network, suggest reaching a large audience with costs offset by advertiser support. In this instance, there is little to be gained by scrambling the signal.

Crystal Balls

Giving a precise estimate of the size of the DBS pie and how it is to be divided is as difficult as it is foolhardy. You can get a general idea by turning to expert researchers. For example, after consulting the woolly worms, International Resource Development stated, in a release for a $985 market report, that "over 15 million US homes will have rooftop DBS terminals by the end of the decade." An announcement publicizing a $1500 report from Strategic Incorporated is slightly more conservative, predicting (1) that DBS won't get a firm start until 1985-1986, and (2) a 1990 sales figure of 160,000 antennas for DBS.

Fig. 1, from International Resource Development, Inc., shows not only the forecasted growth of DBS, but also the effect that it will have on the TVRO industry. Sellers of the backyard terminal can expect a growing market through the mid-1980s but will feel the DBS pinch by 1990. Graphics from Strategic Incorporated (Fig. 2) show that home antennas may constitute a whopping 96 percent of the small Earth stations sold in 1990 yet make up only 45 percent of the dollar volume as a result of the much lower per-unit cost of DBS terminals.

Whither TVRO?

Where does this leave the potential backyard owner and the dozens of firms currently in the TVRO market? There have been no signs that distributors currently using the 4-GHz satellites will abandon them in the near future. To do so would place an enormous burden on the cable-TV industry.

The home TVRO market, which insiders pegged at about 50,000 terminals in 1982, should continue to grow through the mid-1980s. Potential growth stoppers would be federal regulations restricting or prohibiting "unauthorized" reception or a widespread move towards scrambling signals. So far, few suppliers have considered it worthwhile to invest in encryption to lock out the home segment. With time, the suppliers may overcome their reluctance to "deal direct" with the home viewer and offer some sort of plan for authorized home reception.

The entrepreneur who sees the rosy market predictions and wants to join the home-terminal fray faces a tough road. Garage and basement operators are quickly falling by the wayside as firms grow and attract outside capital. The homemade dish on the back of a pickup and the marginal receiver that characterized many early dealers just don't hack it anymore. Ambitious selling and truly innovative products will still catapult the small-time operation upward, but the days of quick profit, if there ever were any, are now over.

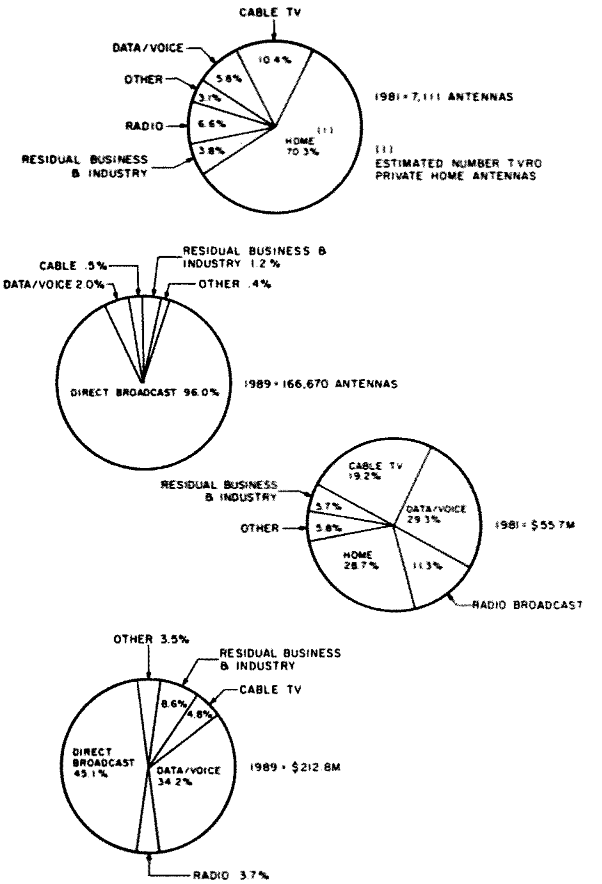

Fig. 2. Research by Strategic Incorporated suggests that DBS sales will capture much of the unit total for the Earth-station industry but consist of less than half of the dollar total.

Jobs

Dismiss all those dreams of the big bucks? No, not necessarily; just recognize that DBS is not going to be an "afterthought" industry with the hobbyist roots that the present-day TVRO field has. A number of the manufacturers have already caught on to this and are claiming that their antennas, designed for 4-GHz reception, will work just fine at 12 GHz. A few companies are even tinkering with Ku-band circuitry. But no matter what technical standards are finally accepted for DBS and no matter who the program suppliers are, there will be a good market for knowledgeable engineers and technicians. After all, someone has to design, install, and maintain those twenty million terminals. ■

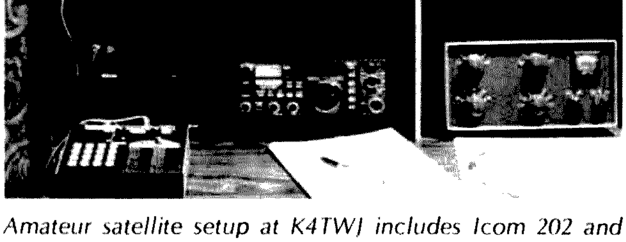
Work the Russian Robot Ops

The robots aboard Russia's two new satellites are cantankerous and challenging. Here are some tips on how to work them.

The recent addition of several Russian spacecraft into the amateur radio satellite program truly has created a flurry of excitement on the HF and VHF bands. In addition to introducing many newcomers to amateur satellite activities, these birds are also renewing widespread interest in mode A communications (2-meter SSB/CW uplink, 10-meter SSB/CW downlink). If you would like to relive the sheer fun and enjoyment of your early days in ham radio—those times when every contact held special meaning and gave you a feeling of accomplishment—you've only to join the action on our amateur radio satellites.

The staggered orbits and comparatively high altitudes of RS (Radio Sputniks) spacecraft afford a communications range and pass-operating time roughly equivalent to the now-classic OSCAR 6 and OSCAR 7 satellites: approximately 1700-km altitude and 25 minutes. Numerous intercontinental QSOs have been conducted each day via the RS satellites, and you can join this excitement with a minimum of effort.

The RS satellites exhibit very high sensitivity, eliminating the need for sophisticated antenna systems or high-power uplink signals. As an example, I recently made fine contacts during an RS pass while using low power (10 Watts) and a J vertical for 2 meters. Mode A communications are the easiest way for HF-laden amateurs to join today's space activities, and the automatic QSOing robots aboard RS5 and RS7 are an absolute blast to contact.



Amateur satellite setup at K4TWJ includes Icom 202 and 40-Watt amplifier for uplink, Icom 730 for downlink. 12-volt power for the 40-Watt amplifier is pulled from the Icom 730's PS15 power supply. SSTV capability included. The programmable Morsematic keyer was used for contacting RS5 and RS7 robots. SF radio desk with upper shelf holding 2-meter gear proves a great convenience for satellite operations.

RS Satellites and Orbits

Two prime attractions of the RS satellites are their straightforward band-to-band frequency relations and their orbital-calculation simplicity. As shown in Fig. 1, each satellite receives signals within a 50-kHz spectrum of 2 meters and linearly relays them within a 50-kHz spectrum of 10 meters.

Each spacecraft's beacon can be used for determining when that bird is within communications range and for indicating when its translator is on/off. The beacon continuously transmits a series of letters and numbers, called information channels. Transmissions containing KØØ indicate the transponder is off; KØ5 to K99 signify that the transponder is operational. Equipped with his own copy of the previously-mentioned frequency-relation chart for

RS5 and RS6		RS7 and RS8	
Uplink (MHz)	Downlink (MHz)	Uplink (MHz)	Downlink (MHz)
145.910	29.410	145.960	29.460
145.920	29.420	145.970	29.470
145.930	29.430	145.980	29.480
145.940	29.440	145.990	29.490
145.949	29.449	145.999	29.499
Beacon	29.450	Beacon	29.500

Fig. 1. Frequency-relation chart which can be used for guiding operations during a satellite pass. An RS6 uplink signal on 145.928 MHz, for example, would be relayed on 29.428 MHz (± Doppler). Allow ±3 kHz on all RS downlinks for Doppler shifts.

a particular RS satellite, the operator is well on his way to enjoying some exciting space-age communications.

The next item of consideration is an orbital-calculation method for accurately plotting a specific satellite's pass. As a matter of convenience, I suggest rounding out each craft's orbital period from 119.xx minutes to an even 2 hours, and each orbital incrementation from 29.xx to an even 30 degrees. These changes are of minor consequence provided they are used in conjunction with reference-orbit information listed each month in the amateur magazines. An OSCARlocator (with RS curves) is also highly desirable, especially when attempting to catch early morning north-to-south passes in the United States.

Assuming a satellite enthusiast is located in the mid-US, his no-problem communications range falls between 70 and 110 degrees. (This information is shown on most world maps.) Assuming a particular day's reference orbit for a selected bird is listed as 220 degrees at 0630 GMT, simply subtract 2-hour and 30-degree steps until the craft falls within range: 220 − 30 = 190 at 0430 GMT, 190 − 30 = 160 at 0230 GMT, 160 − 30 = 130 at 0030 GMT (almost within range), and 130 − 30 = 100 degrees at 2230 GMT (the previous GMT day): a perfect afternoon pass.

Finally, an antenna placement/operating chart is drawn for the selected pass. Since a typical "high in sky" pass lasts approximately 25 minutes and since a couple of minutes can be expected between equator crossing (EQX) and acquisition of beacon signals (AOS), a typical chart will look like Fig. 2. This chart and the frequency-relation chart are then used to "automatically" direct operator actions during the pass (spotting frequencies, incrementing beam-antenna position, etc.). The operator is then free to enjoy communications fun.

Time	Activity	Beam Position
2230	EQX	South
2232	AOS	South
2234	CW	SSW
2236	CW	SW
2238	SSB	West
2240	SSB	West
2242	PASS MIDDLE	West
2244	CW/SSB	WNW
2246	CW	WNW
2248	CW	NW
2250	CW	NW
2252	LOS	NW

Fig. 2. A typical antenna placement/operating chart drawn for a planned RS pass, indicating planned activity and antenna movements. Since this information will be used only one time it can be written on a piece of scrap paper. The uplink antenna in this example is tilted approximately 30 degrees to bypass dual rotor needs.

As RS satellites are quite sensitive, they require only a few Watts ERP (Effective Radiated Power) for successful operations. *Please, gang, bear that fact in mind and control your 2-meter power accordingly!* Transponders on some RS satellites have been continuously knocked off by amateurs running excessive 2-meter ERP. In order to prevent agc clamping and attenuation of others' signals, your satellite-returned signals should *always* be slightly weaker than the beacon (approximately 40-Watts ERP).

Working the Robots

Two of the Russian satellites, RS5 and RS7, carry automatic QSOing robots which conduct separate amateur radio activities approximately 100 kHz below their spacecraft's transponder—see Figs. 3(a) and 3(b). The robot will call CQ, ID (either RS5 or RS7), announce its 2-meter CW listening frequency, and stand by for calls (bedlam, which I will discuss presently).

Satellite	Uplink Receive	Downlink Transmit
RS5	145.826 MHz	29.331 MHz (± Doppler)
RS7	145.835 MHz	29.341 MHz (± Doppler)

Fig. 3(a). Frequencies used by the RS robots for contacts with Earth-based amateurs. Frequencies may vary ±3 kHz with Doppler shift.

Robot:	CQ de RS5 QRU on 145.826 MHz $\overline{\text{AR}}$
Amateur:	RS5 de K4TWJ $\overline{\text{AR}}$
Robot:	K4TWJ de RS5 R QSO Nr 740 RST579 OPR
Robot:	Robot...etc...K
Amateur:	RS5 de K4TWJ R QSO RST579 QTH ALA OPR
Amateur:	Dave...etc...K
Robot:	K4TWJ de RS5 QSL 73 CQ de RS5 QRU...
Robot:	etc...$\overline{\text{AR}}$

Fig. 3(b). QSO format used for contacting robot operators aboard RS5 and/or RS7 satellites. Speed must be between 16 and 20 wpm, and keying must be exact.

Assuming an amateur contacts the robot, he receives a signal report and QSO number, etc., which can be used for QSLing the unique space-type contact. Following a subsequent reply and exchange of 73s, the robot again calls CQ and begins further QSOs. As this article is being written, heavy pileups and ill-informed operations on the robot's 2-meter listening frequency are causing jamming and confusion. Simply stated, *all* stations must take turns calling and working the robot. Transmissions *must* be held to one station at a time, otherwise Morse transmissions become a series of unintelligible dashes or continuous carriers.

The robot's receiving bandpass is approximately 5 kHz, yet any (or all) signals load into memory and are relayed on 10 meters with the same pitch. Thus you can hear the 2-meter input exactly as the robot hears it. If all stations attempting to contact the robot use FM-repeater tactics (transmit only when other stations are not transmitting—an easy task since satellite operations are full duplex), confusion is eliminated and all can enjoy contacts.

Even with those situations dealt with, robot contacts are yet a challenge: RS5 may tell you to send faster (QRQ) or send better (QSD). Despairingly, you load the complete QSO format into a programmable keyer of variable speed and plot a wee-hour pass to avoid QRM. That time, RS5's robot only listens (you hear your 10-meter-relayed signals, but where's the robot?), and RS7 follows a few minutes later calling CQ! The Russians can truly be proud of their designing and programming of these robots. They're clever, inspiring, challenging, aggravating, and fun. If you manage to wrangle a contact, you're a fairly good operator.

Satellite Equipment

There's a good chance you already possess the basic equipment for RS-satellite operations, namely an HF rig with full 10-meter coverage and an all-mode 2-meter rig. You've only to combine these units at one operating location to join the excitement of amateur space communications. Although the RS satellites usually produce a slightly stronger downlink signal than OSCAR 8, a relatively sensitive receiver is desirable (TS-830, TS-130, IC-730, FT-102, etc.). An outboard receiving preamplifier is also quite beneficial, but

not mandatory. Some of the presently-popular 2-meter rigs suitable for RS activities are Yaesu's FT-480R, Kenwood's TR-9130 and Icom's IC-251A. Portable units such as Yaesu's FT-290R or Icom's IC-202 are also grand, although non-QRP enthusiasts may want to add a high-gain antenna or small rf amplifier (operating power can be borrowed from the HF transceiver's 12-volt supply, since very low current is used when that unit is receiving).

The most popular antennas for 2-meter satellite operations are twist or crossed yagis which contain an equal number of horizontal and vertical elements plus a phasing harness for circular polarization. Due to the sensitivity of the RS satellites and the gain of vertical J antennas, however, I've recently experienced quite acceptable results while using KLM's new JV-2 J antenna. That thing really works! Most amateurs merely use crossed dipoles or their triband beam for receiving 10-meter satellite signals. In fact, the RS birds can easily be worked mobile if desired!

Conclusion

The RS amateur satellites represent a true era in both space-age communications and Phase II (low orbit) operations which can be enjoyed by almost every radio amateur. If you're just getting started in amateur satellite activity, I suggest operating RS6 and RS8. The transponders aboard these satellites are somewhat better than RS5 or RS7, and they exhibit less heavy fade. Whichever way you go and whatever gear you use, you will find satellite communications a refreshing new experience in amateur radio. It is indeed tomorrow's frontier in today's world. ■

Ham Radio Hits the '82 World's Fair

When the gates in Knoxville opened, would WA4KFS be ready? Here's the inside story of the World's Fair station.

While the health pavilion was being finished, local hams installed two towers, tribanders, a 2-meter antenna, and dipoles.

John M. Clark N4AQI
509 Cimarron Trail
Knoxville TN 37919

Photos by WD4MQQ

The theme was energy, and amateur radio generated plenty of it—rf and human—during a successful six-month run at the 1982 World's Fair in Knoxville.

SSTV contacts to Europe, the opportunity to send radiograms to the folks back home, rag-chewing on RTTY, and a lot of conversation about the excitement of ham radio were among the activities fair visitors found at the Tennessee Wireless Association exhibit.

Thanks to the tireless work of a group of East Tennessee hams and the generosity of US amateur radio dealers and manufacturers, our worldwide, high-technology hobby continued in Knoxville the long tradition of ham radio at world's fairs.

Officials of the City of Knoxville's health pavilion, where the amateur station was located, estimated as many as half the fair's approximately 11 million visitors could have seen the amateur radio exhibit during the May to October exposition. It was a magnificent showcase for amateur radio.

Plans for bringing amateur radio to the '82 fair began about a year before the event opened. Many of the original group that met at the Knoxville and Oak Ridge hamfests early in 1981 to talk about the idea of ham radio at the fair went on to assume major responsibility for the effort.

The group incorporated itself as the Tennessee Wireless Association, a nonprofit organization char-

Operators from throughout the US and many foreign countries stopped by to operate the station. A commemorative certificate and QSLs were available from the Tennessee Wireless Association.

tered for the sole purpose of sponsoring an amateur radio exhibit at the fair. Under TWA president Ed Dunn W4NZW, the group's first order of business was to approach fair officials about obtaining a site for the station. Virgil Davis KA4RPA, a TWA officer, talked with Knoxville mayor Randy Tyree and secured a location in the city's health pavilion. Health care under emergency conditions was the theme of several exhibits in the pavilion, and the mayor and city officials felt the station would be appropriate there because of the emergency-communications aspect of the amateur service.

The site was superb. The health pavilion was a striking geodesic dome in the center of the fair site, near the Sunsphere, the fair's theme structure. An additional benefit was being located in a high-traffic area near the pavilion's entrance.

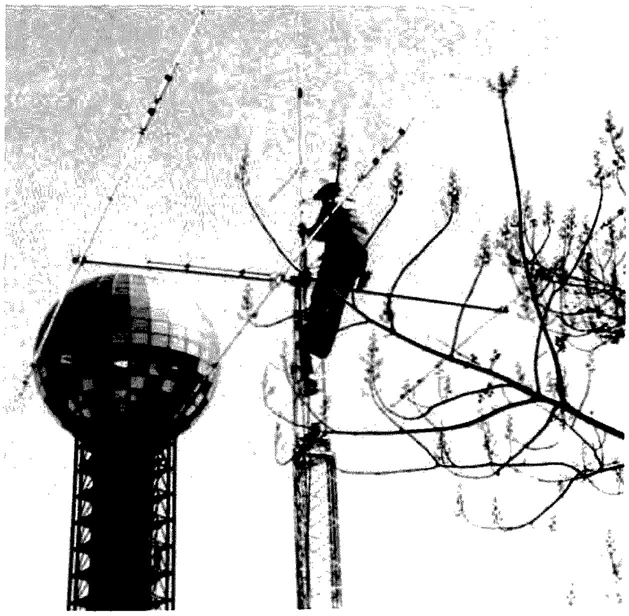
With the exhibit space tied down, TWA officers turned their attention to lining up equipment which would demonstrate the diversity of amateur radio. Ten-Tec, Inc., located in nearby Sevierville, was asked to supply HF rigs for three stations. The company agreed, and Tom Salvetti WD4FVU of Ten-Tec accepted the job as equipment coordinator for TWA.

Amateur dealers and manufacturers responded generously to Salvetti's calls, and approximately $20,000 worth of state-of-the-art gear was loaned and soon on its way to Knoxville.

L. B. Cebik W4RNL, who has written a book on station design, was called on to produce a layout making the most efficient use possible of the 105-square-foot space. Three stations, two designated for general operating and one for specialized communications, were planned.

Although equipment needs were largely met by dealers and manufacturers, funds for installation and operation of the station were needed. Eleven area radio clubs and more than 60 individual amateurs responded, and Jerry Goodchild K4DZR, TWA secretary/treasurer, reported that approximately $2000 was donated to support the station.

Jerry also accepted, with the help of station trustee Chip Coker KD4C, the job of scheduling control operators for the station. About 40 hams each month worked shifts of three to eight hours as control operators. The station was staffed almost all of the 12 hours per day the six-month fair was open.

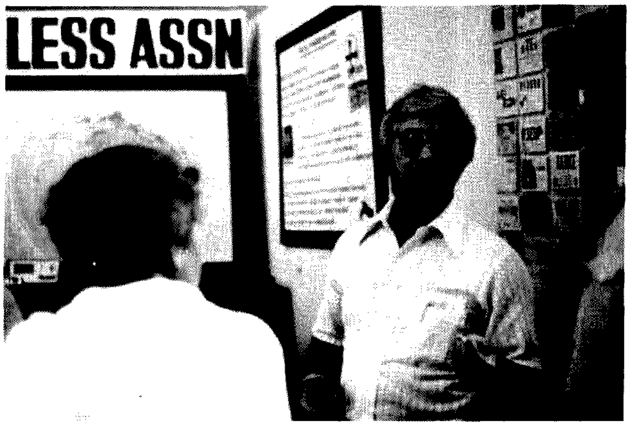


George Child N4BCS installed the 2-meter antenna atop one of the two crank-up towers in the shadow of the Sunsphere.

TWA directors talked about asking the FCC for a special callsign for the station, hoping that Knoxville's hosting the first world's fair in the South would persuade the commission to relax regulations on special calls. Deciding that prospect was dim, Chip KD4C offered the use of WA4KFS, for which he is trustee. Perfect—the phonetics would be "Knoxville Fair Station."

A year-long planning effort by TWA paid big dividends when the time came to install the station. Construction at the fair site was on a tight schedule, with several buildings being ready only hours before the May 1st opening. While work continued on the health pavilion, TWA erected its two 50-foot towers and rotors from Hy-Gain/Telex and Texas Towers. Aboard were a Hy-Gain TH-3 and a V-2 for 2 meters and a KLM KT34A. Dipoles

Three complete HF stations with SSTV and RTTY made up the amateur radio exhibit at the Knoxville World's Fair. Information on amateur radio for non-hams was available at WA4KFS.



With QSLs in the background, Charlie Price WB4VFP explained the many facets of amateur radio to the public.

for 40 and 80 meters were cut, and feedlines from Times Wire and Cable Company were strung and ready to be hooked to the rigs.

The three stations were built around Ten-Tec Omni C transceivers and Hercules solid-state linear amplifiers. Matching tuners, vfo's, keys, and mikes were from Ten-Tec, with MFJ providing memory keyers and clocks. KDK Distributing of Nashville supplied KDK 2036 transceivers for 2 meters. All the gear was housed in stylish consoles from S-F Amateur Radio Services of California.

The latest RTTY equipment was sent to Knoxville by Hal Communications, and SSTV gear came from Robot Research. Both slow-scan and Teletype® attracted a lot of attention from non-hams who stopped by the exhibit.

RCA and Smith-Victor Sales supplied the SSTV camera, monitor, and tripod, and Overman International, which has a manufacturing plant in Knoxville, provided chairs for the station, which was fully accessible to handicapped operators.

A crowd of 82,000, including President and Mrs. Ronald Reagan, enjoyed opening day ceremonies on May 1st. Shortly after the official festivities, WA4KFS went on the air. Pileups were common, as hams around the world wanted an '82 World's Fair QSL card or a special certificate for working the station and 10 other Tennessee hams from May to October.

Amateurs coming to Knoxville were provided with World's Fair information via ham radio. A 2-meter information station was built and placed on the air by Robin Rumbolt WA4TEM. By keying the station on simplex and giving their call, hams received information on parking, shuttle bus service, and lodging. Area repeaters were monitored by operators who could give directions and answer questions about East Tennessee and the fair.

Many amateurs heard of WA4KFS from the 2-meter information station, but a large number said they knew about the exhibit before coming to Knoxville, thanks to the work of publicity director Steve Kercel AA4AK. Some hams spotted the tribanders and followed the coax into the pavilion. All visiting amateurs were asked to sign the guest log at the reception counter and were given the opportunity to operate the station.

And operate they did—all modes, all bands. Some kept skeds they'd made in advance, others checked into nets, some looked for DX. Many added considerable skill to the art of ragchewing.

Control operators answered thousands of questions from non-ham fair visitors and helped hundreds fill out radiograms, which were moved by Anita Teffeteller NG4J, one of the nation's top traffic handlers. Brochures about the station with tips on how to become a ham were given to those who stopped by for a chat.

Several control operators said they found conversations with fair visitors—American as well as foreign—interesting and educational. The foreigners came from Australia, South America, New Zealand, South Africa, Europe, and many other parts of the world.

If you worked the World's Fair station and want a QSL, send an SASE to Harvey Cross W4PKM. You can get the special certificate for working WA4KFS and 10 other Tennessee stations by sending $2 and log confirmation to Sarah Hickey N4EFA.

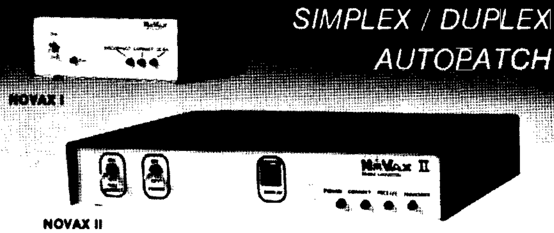
TWA, the 1982 World's Fair, and the amateur community express their gratitude to the manufacturers and distributors who made the "Knoxville Fair Station" possible. Those firms were: Hal Communications, Hy-Gain/Telex, KDK Distributing, KLM Electronics, MFJ, Overman International, RCA, Robot Research, S-F Amateur Radio Services, Smith-Victor Sales Corp., Ten-Tec, Inc., Texas Towers, and Times Wire and Cable Co.

Thousands of people at the fair saw amateur radio at its finest, and East Tennessee hams who served as control operators and repeater monitors threw in a large dose of southern hospitality for good measure.

Look for some new hams on the airwaves because amateur radio went to the fair. ■

Introducing our Latest Model — NOVAX II

SIMPLEX / DUPLEX AUTOPATCH



NOW TWO MODELS TO SERVE YOU BETTER

YOUR OWN PRIVATE AUTOPATCH

NOVAX Mobile Connection

NOVAX interfaces your standard 2 meter; 220; 450; etc. Base station and telephone, using a high speed scan switching technique so that you can direct dial from your automobile or with your HT from the backyard or poolside — Automatically ... Easy installation transceivers, featuring solid state switching, offer best results ... Available interfaced with an ICOM 22U.

Beef Up Your CB-to-CW Conversion

A good bfo will bring your receiver performance up to par. This one is easy to add on.

Penn Clower W1BC
459 Lowell Street
Andover MA 01810

One of the simplest ways to add the bfo function to a converted CB set was described in my article, "CB to CW?—converting the Hy-Gain board," in the July, 1982, issue of *73*. That technique is to leave the transmitter carrier oscillator on during receive so that it beats against the received signals. It is cheap and easy, but does have the drawback of reducing the receiver dynamic range since the bfo signal travels through the entire i-f path before reaching the detector. The rest of that rig turned out so well that the project really deserved a proper bfo to bring the receiver performance up to par. The circuit described here did that job nicely and should also be of interest to anyone wanting to add CW or SSB reception ability to a converted AM-type CB set having a 455-kHz i-f.

The modified circuit consists of a straightforward 455-kHz bfo and buffer used together with a simple product detector in lieu of the existing diode AM detector.

Photos by W1GSL

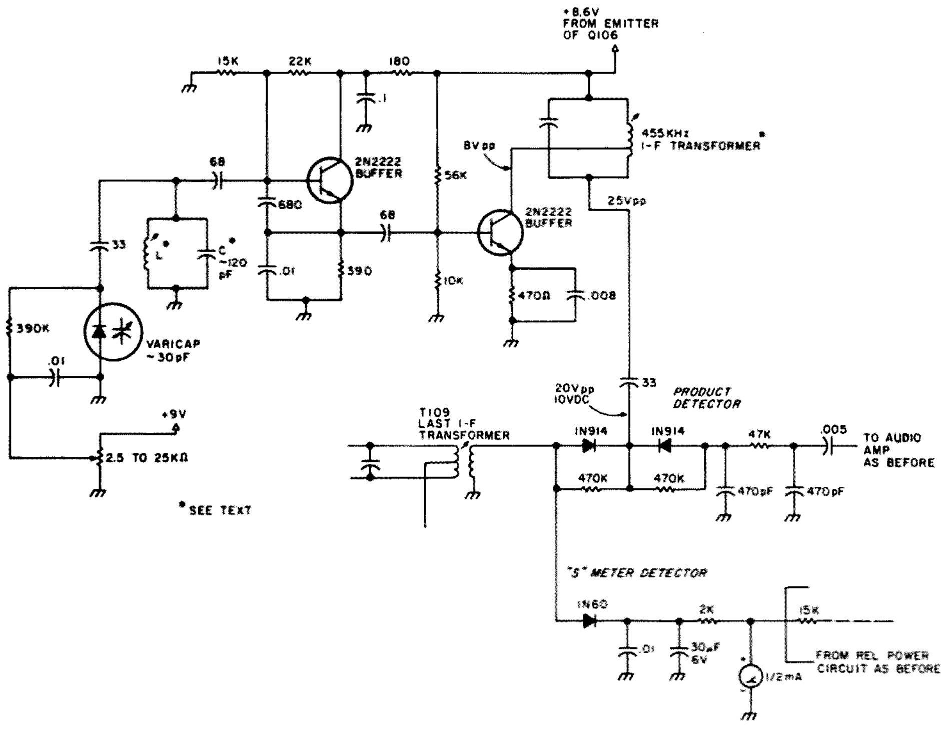

Fig. 1. Schematic diagram of bfo and detector circuits.

"Before" and "after" testing at my home QTH and several local CB hot spots showed a dramatic improvement. The receiver is still capable of copying a .1-μV signal, but the occasional spurious responses are gone. In addition, the bfo frequency is adjustable and can be used for variable receiver offset. The transmitter carrier oscillator provides a signal for transmit frequency spotting and the separate bfo circuit has even made it possible to reconnect the S-meter. One philosophical drawback is that the bfo is a free-running oscillator that introduces the possibility of drift to an otherwise crystal-controlled receiver. The circuit components were chosen so that the warm-up drift is only several hundred cycles; that isn't objectionable given the ability of accurately spotting the transmitter frequency. The transmitter itself is still fully crystal-controlled and (pardon the pun) rock stable.

The Circuit

The circuit diagram for the bfo and detector is shown in Fig. 1. 2N2222 transistors were used in this version, but any NPN i-f transistor from an old transistor radio should work just as well. It is a rare transistor these days which won't work at 455 kHz.

The oscillator coil is fashioned from part of an old tube-type i-f transformer. At first, a miniature 455-kHz i-f can was used as the tank circuit, but the thermal stability was terrible. Simply placing a fingertip on the side of the shielded coil introduced enough temperature change to cause a several kHz frequency shift.

Assuming the temperature coefficient of the ferrite core was at fault, I turned to the older style large i-f can since the inductance there is achieved by using more wire and less ferrite. The top section of the transformer was removed for use as a coil as shown in the sketch of Fig. 2. The coil was paralleled with enough capacitance (120 pF in my case) to get a 455-kHz oscillation with the slug almost backed out of the coil. That step ensures that any change in the slug permeability with temperature will have minimum influence on the oscillator frequency.

In addition, most of the capacitors in the oscillator are polystyrene dielectric types used because of their reputed stability. This step may not really be necessary from a drift standpoint, but it certainly doesn't hurt. The 10-minute warm-up drift of the receiver is only 300 cycles, and that includes drift due to several crystal oscillators as well as the bfo. The bfo frequency can be shifted over a 3-kHz range with a variable capacitance diode controlled from a front-panel potentiometer.

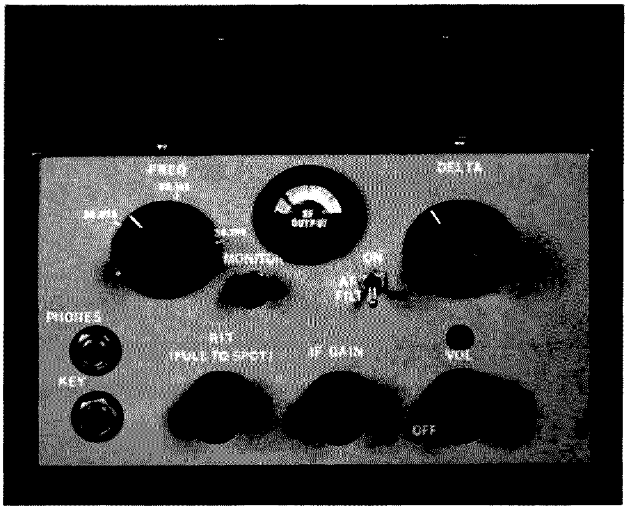
The oscillator is followed by a buffer stage tuned by one side of the miniature i-f transformer. The transistor collector drives a tap on the coil and the detector drive is taken off at one end. This steps up the available drive signal from 8 to 25 volts peak-to-peak. The drive level is not critical, but in general the bfo injection should be about 10 times the expected signal level. If a number of transformers can be salvaged from old radios, a suitable one can be selected with the aid of a simple voltmeter circuit like that suggested in Fig. 3. Use an ohmmeter to find which windings have a tap, then put that coil in the circuit and check the output voltage with the meter. Don't forget to try swapping the dc feed and output ends of the coil to find which hookup gives the most output level. Any drive above 10 to 15 volts peak-to-peak (3.5 to 5.5 Vrms) will be satisfactory.

The two-diode product detector works like a pair of SPST switches which make and break the connection between the i-f output and the following audio amplifiers at a 455-kHz rate. The 33-pF coupling capacitor charges up to the peak value of the bfo sine wave and that makes the final buffer tuning easy—just hang a high impedance dc voltmeter on the junction of the two diodes and tune the buffer for maximum. The larger this voltage, the more signal the detector can handle without overloading and the less you will have to use the i-f gain control.

Since now only off-the-air signals are coming through the i-f stages, a simple envelope detector is incorporated to drive the S-meter. With the .5-mA meter and the resistor values shown, the sensitivity seems about right. Since there is no agc in use, the meter reads in a linear instead of logarithmic fashion. That limits its usefulness somewhat but didn't seem serious enough a problem to merit the complication of a meter amplification circuit. For those interested in a more accurate meter action, I would recommend looking into agc operation as well.

Construction

It is best to place the bfo circuit close to the detector physically. In my rig, the above-board space in that area was occupied by the active audio filter modification, so the bfo circuit was built on a small board and mounted underneath the chassis. The product detector circuit is easy to fit on the main board and the connection to the bfo can be made short and direct. This helps to prevent the bfo from coupling back into an earlier section of the 455-kHz i-f strip.



The bfo control (labeled RIT) is mounted where the sidetone level pot used to be. That control (now called MONITOR to save space) is mounted just below and left of the meter.

As shown in the photograph, the bfo frequency adjust pot (labeled RIT) is mounted in the hole formerly occupied by the sidetone level control. That control is replaced by a miniature pot and knob mounted at the former location of the transmit offset switch. The circuitry for offsetting the transmitter is removed from the 10.695-MHz oscillator, as now the receiver can be offset by means of the bfo control. The bfo pot used has a pull-on, push-off switch attached and that is used to turn the 10.695 oscillator on to permit spotting the transmitter frequency with the receiver.

There is a frequency inversion in the receiver conversion process; be sure to wire the bfo pot so that a clockwise rotation lowers the control voltage (and

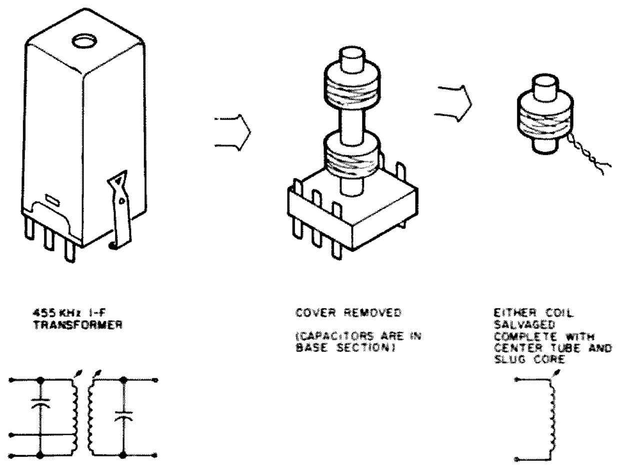


Fig. 2. Details of salvaging the coil from an old 455-kHz transformer.

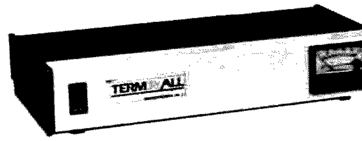
TERMINALL

RADIO MODEM



apple* TRS-80* ATARI*

SEND & RECEIVE CW & RTTY

TERMINALL is a hardware and software system which converts your Personal Computer into a state of the art communications terminal.

- TERMINALL is easy to use. Plug into your receiver headphone jack and copy Morse code or radioteletype. Plug into your CW key jack and send Morse code. Attach a Microphone connector and send Baudot or ASCII RTTY using audio tones (AFSK). That's all there is to hooking it up.
- Fantastic Morse reception. No adjustments are necessary to receive Morse code. It's fully automatic! Six stage active filter demodulator and auto adaptive Morse algorithm copies the weak and sloppy ones.
- Separate RTTY and CW demodulators. Built in crystal controlled AFSK, CW and PTT keying, 60 mil loop interconnect, RS 232 IN and OUT, hand key input and side tone output.
- Built in parallel printer driver software allows hardcopy in all modes.
- Hardware clock maintains accurate time.
- Multiple user defined WRU functions. You select initiate sequence, terminate sequence, what to transmit back and whether to save on tape or disk.
- Word wrapping, word mode editing, diddle, ignore carriage returns, user programmable end of line sequence, adjustable carriage width, transmit delay (fixed, none or auto adaptive), excellent documentation, break mode and much more.
- TERMINALL has capabilities far surpassing dedicated terminal systems. And since it works on a general purpose computer, the majority of your investment (your computer) is spread out over many different applications. **You get more for your money.**
- Complete with software on cassette and diskette, assembled and tested hardware, and extensive instruction manual. Call or write for specifications on TERMINALL for TRS-80 Model I or Model III, Apple or ATARI 400/800 COMPUTERS. **$499.**
- 15 day money back trial period. One year parts and labor limited warranty on factory direct orders.

with it the bfo frequency). This will result in clockwise knob rotation moving the receiver up in frequency as you would normally expect.

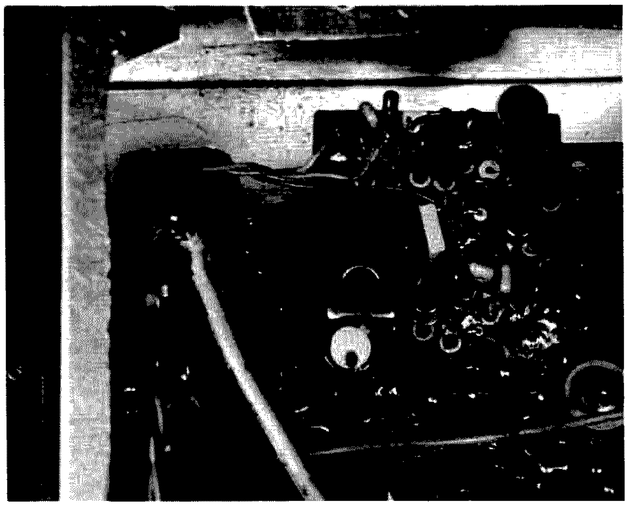
Operation

There was a time when the typical amateur receiver had a different calibration scale for each band. Now just about every receiver has a single 500-kHz tuning range which is switched to cover each band. These tunable i-f receivers contain a set of crystal-controlled frequency converters which move the selected segment of the radio spectrum to the input tuning range of a single-band receiver. In this 10-meter receiver, the bfo tuning provides exactly the same tunable i-f feature on a smaller frequency scale. Because the i-f passband of this receiver was designed for AM reception, it is about 10 kHz wide and can pass quite a few CW signals. The bfo and product detector can be thought of as the front end of a direct-conversion receiver which is able to tune across this 10-kHz band segment and pick out the desired signal. In the complete CW transceiver, the transmitter frequency always appears exactly in the middle of the i-f tuning range, so in practice most transceiver tuning is done with the channel switch and delta tuning control while the bfo control is used to provide a RIT (*R*eceiver *I*ncremental *T*uning) function.

Most contacts are made with both stations on the same frequency; the receiver is easily set for this condition by pulling out the RIT knob (that's how I labeled the bfo control) to turn on the transmitter carrier oscillator. The RIT control is then turned to tune in the transmitter frequency and produce a desired tone in the audio output. The knob is pushed back in to turn off the spot signal; when an incoming signal is tuned via the channel selector and delta tuning controls so as to produce the same beat note, the transmitter will automatically be zero beat with that received signal. There is one caution to remember when using this procedure. As with all direct-conversion receivers, the detection process will produce a note on either side of zero beat, so a little care is necessary to ensure that the proper side is chosen. Actually, this is quite easy. If the RIT knob was rotated clockwise (or counterclockwise) from being zero beat with the spot signal, then the delta tuning control should also be rotated clockwise (or counterclockwise) from being zero beat with the received signal. Generally, the bfo will be offset 800 Hz from the transmitter by peaking the beat note in the audio filter. Then the RIT control is only used as necessary to dodge QRM or follow the other fellow's frequency drift.

Conclusion

This last modification makes a good rig even better. The independent receiver tuning is appreciated at least as much as the freedom from occasional CB overload. The bfo addition also opens the door to one last area of interest: i-f derived agc. Either the S-meter detector or one similar to it could be used to control the gain of the receiver in much the same way as Hy-Gain intended. A possible drawback of this scheme would be agc action caused by signals adjacent to the desired one in the wide i-f passband. Perhaps some readers will enjoy experimenting along this line. ■



The bfo and buffer circuits are built on a small board mounted below the front right-hand corner of the circuit board. The volume control is visible just to the left of the added board. The disgraceful saw marks on the lower lip of the main chassis happened when the chassis top was removed to mount the main board.

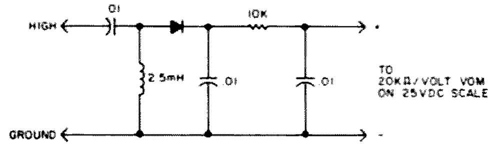


Fig. 3. Simple rf voltmeter which can be used to measure detector drive level.

Julie Collins KL7RD
Alaska 99757

The Denali Connection

Disaster struck these two hams in the backcountry of Alaska. Only a tenuous radio link to civilization could save them.

Although I passed my Novice code test and exam in November of 1980, my first contact was not until April, 1981, five months later. Even when it happened, I had no real enthusiasm about being on the air. I felt a sense of grim despair, perhaps, but no enthusiasm.

This may seem peculiar to the many hams who turned on their rigs and dove into the airways the minute they received the anticipated envelope from the FCC. Well, when I got my letter, I glanced at it and stuffed it casually into my pocket before wandering on home from the post office. That little stroll took nearly two hours, for the post office is six miles from my home. I was on foot with a heavy pack, I was breaking trail through the snow, and it was 35 degrees below zero.

I have lived in the Alaskan bush all my life, and with no telephone and once-weekly mail, instant communication can be an extremely precious commodity. Hence, the radio license is the most feasible and dependable means to find help in an emergency, to relay your whereabouts to your anxious family, or to let the folks know you just shot a moose and the winter's meat is hanging.

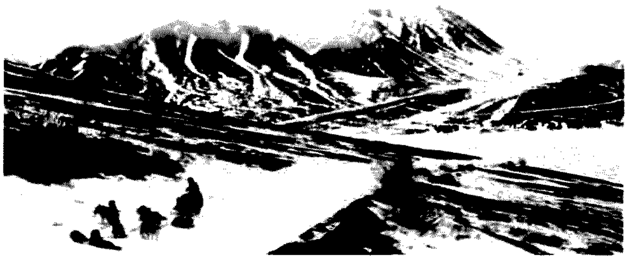
Unfortunately, the simple fact of the matter is that I just wasn't cut out to be a ham. I didn't have much trouble picking up the code, but copying frustrated me and the bookwork

Photos by Miki Collins WL7AOM

Our home in central Alaska is located on a remote lake north of Denali. The big log cabin is studded with various radio antennas which my father has set up.

As far as the eye can see, there is nothing but snow and mountains. Spend a few days in a place like this and you forget civilization can still exist.

Miki Collins WL7AOM gives the dogs a break while she ties down the load in the sled. Bouncing over bare tundra like this was only part of the pile of troubles we had on this ill-fated trip through Denali National Park.



We had a good team, but after a few days they began to grow run-down. We rested them often, especially while climbing over passes. Stony Hill is in the background.

really got me. I didn't have friends or instructors; I just taught myself from books. When you start out hating math, despising physics, and abhorring electrical principles, you aren't doing so hot.

Once I began to understand it a little better it was a lot more interesting, but even so I just wasn't cut out for it even though both my parents and my brother have ham licenses. I didn't become a ham because I wanted to. I did it because I had to.

I was attending college when I got my license and had no use for it at that time. It sat in my pocket, its privileges not exercised. Until, that is, that fateful day in early April when my sister Miki and I ran out of time.

Generally speaking, around here running out of time is synonymous with running out of dog food. On this particular occasion, we were embarked on a 10-day dogsled trip through Denali National Park. (Denali is the Alaskan name for Mt. McKinley.) With something like 150 miles to go with our 8-husky team, it was naturally quite a disappointment to break one of our only pair of skis the first day out, for this would considerably diminish our speed.

Undaunted, I set up our tiny 80-meter rig, stringing the long antenna through the scrubby spruce bordering the Teklanika River with the intention of letting our folks know that our progress might be delayed. My first contact! Or was it?

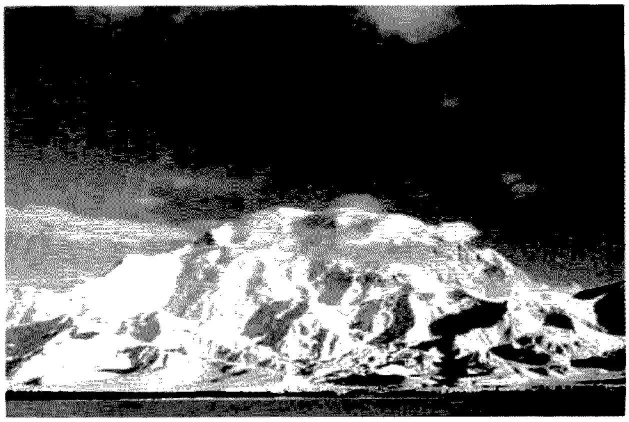
All the suspense and exhilaration of getting on the air crashed down when the tuning knob broke off in my hand and, as it was nearly dark, I could not hope to fix it that night. By morning, my already dampened enthusiasm for the wide world of radio had plummeted and I resolved to leave the nasty set in the bottom of a tattered burlap bag.

On the third day out, we used the broken ski to jury-rig a broken sled runner. The fourth day, our eight sled dogs got wind of a grizzly bear fresh out of hibernation and led us on a tumultuous chase for two miles along the glare ice of a creek before we pulled them under control.

Six more days of increasingly difficult travel saw us less than 100 miles out. Blizzards, deep soft snow, and open creeks slowed our progress as much as the broken sled runner. By the tenth day, we were quite out of dog food. The sled was shot, broken from crashing down 30-foot snowbanks, sliding down steep gullies, and crossing rocky glacial outwash plains. The snowshoes were shot, making trailbreaking nearly impossible, and the dogs were shot—tired, run-down, hungry, and discouraged. We were shot. The trip was shot.

Miki and I pulled off the broad creek we had been on and set up camp in a grove of spruce. My sister built a fire. I dug out the radio.

The 80m call for help.



The 20,320-foot Mount Denali rises about 17,000 feet up from a fairly flat base on the north side where we were traveling. This mountain has the peculiar ability to reflect radio signals so that any two points that can see a particular face of the mountain can communicate by 2 meters; a knife-edge effect allows communication across the top of the mountain.

I swear I didn't believe I could make it work. I am by no means an electrical genius. Aside from this, my sister and I had been totally alone for 10 days. We didn't even know President Reagan had been shot and seriously wounded nearly a week before. We had spoken to no one but each other.

When you are alone in the woods or on the tundra for any length of time—even as little as ten days—and when you are surrounded not by humanity but by natural wonders, when the dominant theme in your life is the magnificently towering Mount Denali, then you begin to suspect that you are the only human being in existence. You are nothing but a bit of human dust floating through the broad expanse of natural wonders—you are alone, dependent on yourself, your ingenuity, and your strength to keep you alive. There is no one else—no one else at all. Civilization and the magic of radio just don't exist.

That's why I didn't place one jot of faith in my ability to communicate with the outside world. Inwardly, I cursed the great and powerful FCC for giving me the privileges of using a medium I felt I knew nothing about. I was, in my humble estimation, unqualified, incompetent, and inadequate. But I had no choice. If I didn't make contact, we could well have another 50 miles to go with hungry dogs, breaking trail at one mile an hour or less through snow that was knee- to hip-deep.

So I tried. For one horrible instant it occurred to me that I might have forgotten my callsign, but no, I was WL7AOL, and my father, whom I was calling, was KL7IS. For another horrible moment, the battery seemed dead, but no, after warming it by the fire, it sparked to life.

The line from the radio to the antenna was just a couple of feet long, so I stood up in the dogsled holding the radio near the antenna. Jamming the tiny plug into my ear, I began awkwardly poking the tiny button-key. I had to use my thumb since the fingers of one hand were occupied with the ear-plug which kept slipping out, and those of my other hand were supporting the radio. *KL7IS, KL7IH* ... oops ... *KL7IS* ... uh ... *DE* ... Good heavens! What was W? Oh yes! *WL7AOL.* I pushed the switch to receive, my thumb icily cold.

I planned to listen a minute or two before calling again, and again, and again, for five or ten minutes before giving up until nightfall when I was more likely to raise someone. But hardly had I turned over the switch when to my astonishment there was a prompt reply! Glory be! It was a faint signal but steady, sneaking softly from the ear-plug into my ear.

The radio was slipping from my fingers and the ear-plug from my ear, but I was so stunned I could only choke and sputter. When I had recovered from my shock, I shoved the radio hastily to Miki, snatched up a map—the only available piece of paper—and with trembling fingers scribbled madly on the back. Daddy was sending slowly, but the best I could do was take down the dits and dahs as such and translate later. Then, shoving the map to Miki and snatching back the radio, I painfully sent out my message, not only to Daddy but to hams all over the great outside who might be monitoring.

The following day we were picked up by bush plane and flown home with our dogs. And that is the story of my first contact. It epitomized the very reason I went for my license—so that I could communicate in times of need.

It will never be a hobby with me; I will never enjoy DXing, bunny hunts, or other ham sports, but ham radio will serve a purpose for me just as it does for many hams in less isolated areas: the purpose of communication. ■

Error Protection for Your Digital Transmissions

Block coding can make your signal 100% error-free. . . hopefully.

In a previous article ("Computers and HF," *73*, January, 1981), I discussed the direction I thought amateurs should go in developing inter-computer data communications techniques on the amateur bands. (By "data" here I mean 8-bit ASCII characters which may be making up formal messages, a digital TV image, computer graphics, or anything else.) In my opinion, the best course is to pursue frequency shift keying schemes since diversity reception of the mark and space frequencies may be used to gain interference immunity. Since small computers are to be used at each end of the communications link, error-detecting or error-correcting codes should be used to allow error-free reception of the basic data even over a communications channel which produces transmission errors. Central to the success of these schemes will be block coding of the basic data and the ability of the receiving computer to request retransmission of data blocks that were garbled.

In this article I will discuss in some detail one implementation of an automatic repeat request (ARQ) inter-computer link using error-detecting block coding. This discussion is intended to form a basis for conducting experiments with this technique (with special FCC approval).

Background

We are trying to design a system that will allow error-free transmission of data over a radio channel degraded by noise, fading, and interference from other stations. The most important characteristic of this channel is that we can expect it to produce transmission errors. We must therefore design our system to recognize when errors have been encountered and to somehow correct them. We will assume that our channel is at least good enough to allow error-free reception *occasionally*. The computers will then keep trying to transfer their data and retransmit that data destroyed during periods of interference on the channel. Though we will be able to get our data transferred without errors even on a very degraded channel, many retransmissions may be required. This means that the worse the channel is, the longer it will require to transfer (without errors) a given size file.

Error-Detection Coding

The first thing we must be able to do is transmit our data in such a way that the receiving computer can positively determine when it has received it correctly and when it has not. We do this by error-detection coding. There are a number of schemes for doing this, and I will not attempt to explain all of them. Each scheme has its own advantages and disadvantages, but in my opinion, the best scheme for our purposes is the "checksum" method.

With this method, the sending computer breaks down the data into blocks with a certain number of characters in each block. Then it numerically adds all the characters together (thinking of them merely as 8-bit binary numbers). This 8-bit sum, called a "checksum," is then transmitted at the end of the data block. When the block is received by the receiving computer, it adds together all the characters in the block as *it* received them and compares this sum to the checksum that it received over the link. If the two sums match, the receiving computer can be fairly sure that it received all the characters with no errors in the block, but it cannot tell which characters have been garbled.

Automatic Repeat Request

Once we have the capability to determine when we have received good data blocks and when we have received garbled data blocks, the next step is to get the sending computer to retransmit the garbled ones. This is done by a system called automatic repeat request (ARQ).

The sending computer will normally send a number of data blocks in one transmission. At the end of its transmission, the sending computer waits for response from the receiving computer which will indicate if it needs any of the blocks retransmitted due to errors. The sending computer will then begin a new transmission and include at the beginning a repeat of blocks requested by the receiving end. These repeated blocks will be followed by new data. This process continues until all data has been transferred.

During the reception of the data blocks, the receiving computer keeps track of the blocks that are received error-free. At the end of the transmission, it sends a short message back to the sending computer acknowledging the blocks that it received correctly (an ACK message). The sending computer then assumes that all other blocks were not received correctly and repeats these in its next transmission.

If for some reason the ACK message back to the sending computer is garbled, the sending computer will simply assume that all blocks in the previous transmission were garbled and will repeat them all. This is safer than allowing the possibility that some garbled data blocks might not be repeated when required. If blocks that have already been correctly received are again encountered by the receiving computer, they simply will be ignored. The important thing is that we receive every data block correctly at least once.

This process obviously requires some "intelligence" in the terminal equipment at both ends of our communications link. This will take the form of a computer and suitable program to accomplish the required arithmetic, buffer storage, and record keeping. These tasks will not be difficult to do with a small computer, but they are much beyond the capability of an ordinary TTY machine. (This is why straight TTY machines are referred to, with no disrespect intended, as "dumb" terminals.)

Block Length

We need to be careful about the chosen length of our data blocks. If, for example, our channel on a given day is producing errors about twice per minute on the average and we have chosen a block length that requires 3 minutes to transmit one data block, it is obvious that we may never be able to receive even one block error-free. The sending computer will be forced to continually repeat the first data block of the file, and the file may never be completely transferred. (Our communications system, in this instance, would have broken down.) On the other hand, if we chose data blocks to be so short that they only required 100 milliseconds to transmit, we would be able to transfer many data blocks error-free over our example channel.

If we make the blocks too long, we find that we seldom receive error-free blocks and we spend too much time retransmitting. If we make the blocks too short, our overall rate of data transfer ("throughput") is reduced under good channel conditions because we are spending too much of our time transmitting checksums instead of data characters. If we could reliably predict what our channel would be like all the time, it would be possible to find a block length that was the most efficient all the time. But on some days you may have a telephone-quality channel, and on other days the interference may be severe.

For this reason, I am recommending that the block length be variable and under the control of the sending computer (and/or operator). This will allow the block length to be optimized from one transmission to the next, if desired, simply by experiment. One would normally want to begin with a fairly short block length (perhaps 16), and then increase it if few retransmissions are necessary. If, at another time, the retransmission rate gets too high, the block length could simply be shortened on the next transmission.

Signal Format

There are a few other details we must consider in order to make our scheme workable. We require three types of data structures: (1) a block of text characters, (2) an acknowledgment block, and (3) a block of characters to signal the end of transmission.

Fig. 1 shows how a text block would be constructed. It may be preceded by any number of ASCII SYN characters as fillers. The STX (ASCII Start of Text) character flags the start of the block. Following STX are a variable number of 8-bit data bytes. The number of bytes may vary between individual blocks in a given transmission, but it may not exceed 256. The end of data in a block is signalled by the ETX (ASCII End of Text) character. Immediately following the ETX is the 8-bit checksum and then the 8-bit block label.

The checksum is formed by numerically adding together each data byte and discarding any register overflow. Each data block of a transmission must be uniquely identifiable, so we add the block label. The sending computer will sequentially assign 8-bit labels to each data block it sends. These will allow the receiving computer to identify the blocks it has received correctly, and also allow it to properly sequence the data blocks after they have all been received correctly.

Fig. 2 shows how an acknowledgment block would be constructed. It also may be preceded by any number of SYN characters. An ACK (ASCII Acknowledge) character flags the start of an acknowledgment block. The contents of the block are the block labels of the text blocks received correctly during the previous transmission. We will allow a variable number of labels, up to 256, in one ACK block. The end of the block is flagged by an ETX character. No error-checking will be done on the ACK blocks, so no checksum or block label is transmitted.

Fig. 3 shows how an end of transmission would be indicated. The ASCII ETB (End of Transmission Block) character will be used to indicate to the receiving computer that it may begin transmitting. To ensure that at least one ETB is received even with interference, it will be sent 5 times. After recognizing the ETB character, the receiving computer will wait until the loss of receive signal is detected and then begin transmitting.

We want to allow the use of many different types of computers to process this code. Since different computers will require different amounts of time to perform the arithmetic and bookkeeping operations necessary to process data blocks, we cannot know for sure how much time must be allowed between blocks. To make sure we don't make it impossible for some computers to keep up, a vari-

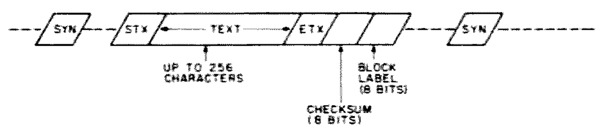

Fig. 1. Text block.

Fig. 2. ACK block.

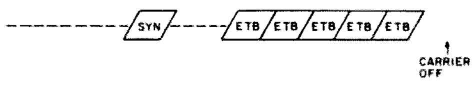

Fig. 3. Transfer of link control.

able number of SYN characters will be transmitted between data blocks. Depending upon the speed of the receiving computer, any number between 1 and 10 SYN characters might be required to allow adequate processing time at the receiver. The number of SYN characters transmitted between blocks can be varied to suit the sending or receiving operators. A certain minimum number of characters will be necessary to allow the receiving computer enough processing time, but any number of additional SYN characters will not disrupt the scheme, since the receiving computer will simply wait until it encounters an STX character to start processing the next data block. The only effect of sending more SYN characters than actually needed will be to reduce data throughput below the optimum for that combination of computers.

Another reason to allow varying the number of SYN characters is that we want to be able to use this scheme over a variety of actual data rates. Since the computer processing time will remain fixed while the character transmission time may change considerably, it will be advantageous to use fewer synchronizing characters at the lower data rates and more at the higher data rates to allow the same processing time at the receiving computer.

This system does not lend itself well to informal conversation at low typing speeds and would primarily be of use after initially establishing contact with another station and mutually deciding that a large block of data (perhaps 100 formal messages) is to be transferred. At this point, both stations would switch to the block-encoded mode to transfer the data.

Once in the block-encoded mode, we would begin a transmission with a leader of SYN characters perhaps 5 seconds long. The remainder of the transmission would consist of ACK or text blocks. We will require that the text blocks be transmitted sequentially, but we will allow the ACK blocks to appear anywhere during the transmission. Since we will not be using error-detection on the ACK blocks, it will be a good idea to send the ACK blocks more than once to make sure they are received correctly. Between blocks any number of SYN characters may be transmitted. The last block of the transmission will be followed by several SYN characters and then the five ETB characters to signal the end of transmission.

Diversity

How can diversity operation help us in this scheme? If a receiving interface is available where the mark and space frequencies can be detected independently, the receiving computer can treat the two frequencies as separate signals, and we get two chances for each data block to be received correctly. If either the mark or space channel produces an error-free block, the receiving computer can ACK that block. This can greatly reduce the number of retransmissions under moderately degraded conditions and greatly increase throughput.

Summary

I have described one of several possible methods to achieve error-free transmission of digital data over a very imperfect radio channel by using error-detecting coding, ARQ, and computers at each end of the radio link. I hope these ideas will help to get some experimenting underway in this direction.■

Introducing The SRT-3000 A High Performance RTTY Communications Send-Receive Terminal

• Built-in demodulator & AFSK modulator for 170,425,850 Hz shifts, high and low tone pairs • 60,66,75,100,132 WPM Baudot, 110,300 Baud ASCII, 5-99 WPM Morse • 1000 character text buffer with BREAK feature • Ten 80 character message memories with battery backup • Selectable display formats, 24 lines x 72 characters (2 pages), 24 lines x 36 characters (4 pages), 16 lines x 36 characters (6 pages) • Split screen operation • On screen status line displays a tuning bar, mode, speed, shift, tone pair, normal/reverse, USOS, WRU, SELCAL, buffer mode and buffer count • Cassette interface for long "Brag Tapes" or unattended message storage • Baudot and ASCII printer outputs • Built-in audio monitor • Built-in 110 VAC power supply • Other features—PTT control, WRU, SELCAL, sync Idle, CW ID, USOS, autostart, full or half duplex, scope outputs, weight control, intercharacter spacing, reverse video, RS-232, word wrap around • Compact size only 13.3 x 10.3 x 4 inches • Made in USA.

Drive-Time SWLing

This simple car radio converter will open up a whole new world of driving.

Tired of rock music on your car radio? Then listen to the BBC, Voice of America, Radio Canada, and other shortwave broadcast stations. Only a 2-transistor converter is required.

The circuit converts the 16-, 19-, 25-, or 31-meter bands to AM standard-broadcast frequencies. Simply insert the converter between your car antenna and antenna input.

Maybe you prefer your shortwave listening indoors. Then you will need a low-cost surplus car radio (Olson Electronics, 260 S. Forge St., Akron OH 44327) and a 12-volt power supply (Radio Shack). The car radio is well shielded and will not pick up AM standard-broadcast interference.

The converter schematic is shown in Fig. 1. The simple Pierce oscillator circuit uses a 2N5397 JFET to restrict oscillator output noise. No tuned circuits, other than the crystal itself, are used in the oscillator. The 3N204 MOSFET mixer provides low noise, good dynamic range, and moderate gain. Mixer gain must be high enough for antenna noise to mask the car radio internal noise. On the other hand, mixer gain must be low enough so that overloading of the car radio by strong signals is not a problem. Thus, the higher-gain 3N211 is not recommended here.

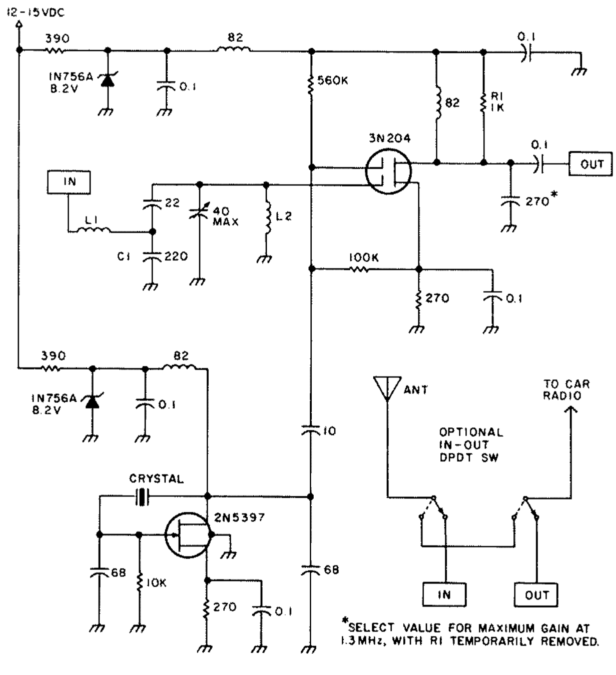

Fig. 1. Schematic for the converter for shortwave listening.

Temperature tests show the converter performance to be virtually constant over the range −40° C to 85° C. Oscillator frequency drift, for a 16.3-MHz AT-type crystal, is less than ±1.5 kHz over this temperature range.

Crystal* frequencies are selected so that one crystal can be used for two shortwave bands. Signals from these two bands do not overlap. The mixer input circuit selects one of the two bands. Table 1 lists the values of L1, L2, and the crystal frequency for each band.

*AT-element, fundamental mode, parallel-resonance, 32-pF load capacitance. Jan Crystals, PO Box 06017, Ft. Myers FL 33906. Cost is approximately $5.00.

The values of L1 should work well with GM windshield antennas. Regardless of the antenna type, L1 should be selected for maximum signal strength at center band. L1 and C1, in addition to matching the antenna to the mixer, act as a low-pass filter at TV and FM broadcast frequencies. This filtering function is very important since unattenuated signals from powerful VHF stations can produce undesirable mixer products at the converter output.

A 19-meter version of the converter is mounted under the dashboard of my Chevrolet. Standard broadcast

SW Band	Xtal Freq.	L1	L2
16m	16.3	1.5	1.8
19m	16.3	1.8	2.2
25m	11.0	2.7	3.9
31m	11.0	3.9	5.6

Frequency in MHz.
Inductance in microhenries.

Table 1.

feedthrough causes no significant interference with shortwave signals. More specifically, a 1-kW station at 1.1 MHz is not detectable beyond a half mile from the station antenna. For negligible feedthrough, the converter must be contained in an aluminum box. Also, a shielded cable (Radio Shack) must connect the converter to the car radio. To avoid generator/alternator whine, the converter box must be securely fastened and grounded to the metal frame of the dashboard with sheet-metal screws. To control ignition noise, resistor-type spark plugs must be used in the car engine.

The converter circuit is constructed on top of an unetched, copperclad PC board. No etching or cutting of the board is required. Circuit grounds are soldered directly to the board. A few ¼-Watt, 4.7-megohm resistors, with one end of each soldered to the PC board, are used as standoffs. The crystal socket is epoxy-glued to the board. Inductors must be at least one inductor diameter from the PC board. All inductors must be separated by at least two inductor diameters. Naturally, all circuit leads are kept short.

All resistors in the schematic are ¼-Watt carbon with values in Ohms. All inductors are molded rf chokes, unshielded type, with ¼-inch-length bodies and values in microhenries. Integer values of capacitance are in pF, and the corresponding capacitors are ceramic or dipped mica. Decimal values of capacitance are in μF, and the corresponding capacitors are ceramic.

One final note. Experience indicates that, after installing the converter, one should tune the car radio while keeping one's eyes on the road. ■

Stop That Heist!

What would you say about an alarm that's portable, inexpensive, and goes off when a thief just touches the doorknob? We say build it.

Dennis Pharr WD5JWY
3521 SE 45th Street
Oklahoma City OK 73135

This article will describe a low-cost alarm circuit that is activated by a simple touch of the hand. Its operation depends upon a source of 60-Hz signals that is present in virtually all homes wired with standard 110 V ac. The sensitivity of the alarm is adjustable and easily varied to suit the particular 60-Hz environment. The alarm requires no installation; it is simply hung on the doorknob by a hook formed from heavy-gauge copper which is connected to the input circuit. When the doorknob is touched, the alarm will sound.

Circuit Operation

Operation of this circuit is fairly simple. Referring to Fig. 1, when the doorknob is touched, a 60-Hz signal is applied to the gate of FET Q1. This signal is then amplified a small amount and applied to the trigger terminal (pin 2) of U2, which acts as a one-shot. The output of U2 then goes high, causing the output of the Set/Clear flip-flop, which consists of U3A and U3B, to go high also. The high on the output of the Set/Clear flip-flop enables audio oscillator U4 which acts as the alarm. The alarm will continue to sound until it is reset by depressing push-button S2.

Also built into the circuit is a delay feature which will allow the alarm to be used while you're away from your house or apartment. The delay portion of the circuit, made up of Q2, U1, and U3C, allows you to activate the alarm and go out the door while still handling the doorknob.

Operation of the delay circuit is also quite simple. When power is initially applied to the circuit, a trigger pulse is generated by Q2 which causes the output of U1 to go high. The high on the output of U1 is inverted to a low by U3C and applied to pin four of U2. This low on pin four of U2 disables the alarm for approximately thirty seconds, with the components specified. This should be plenty of time to exit the door. If you don't wish to include the delay feature, simply leave out Q2, U1, and U3C and connect pin four of U2 directly to Vcc.

Quiescent current drain of the circuit is about fifteen milliamperes with the nine-volt battery specified; therefore, two nine-volt batteries in parallel or six penlight cells in series should be used for powering the alarm.

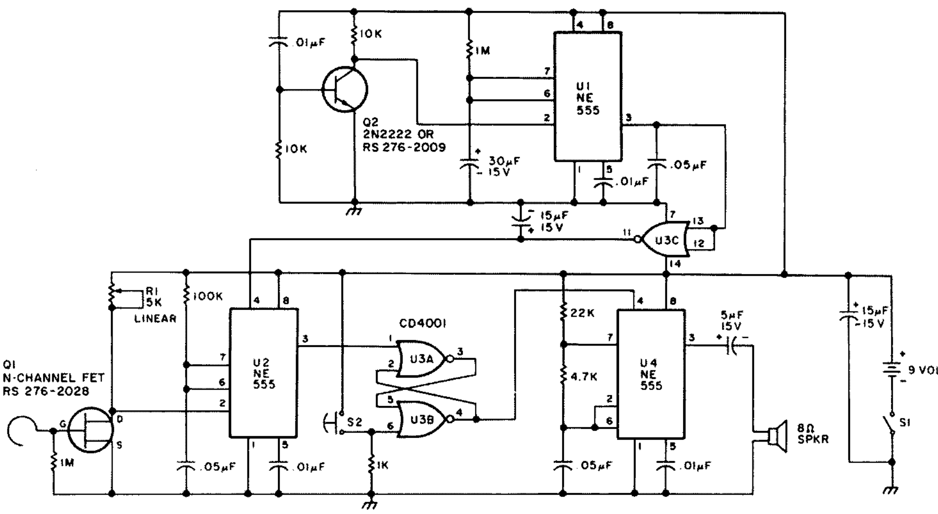

Fig. 1. Schematic diagram of touch alarm.

Construction

The circuit can be built most easily using perfboard-type construction. Sockets should be used for all the ICs, should replacement become necessary. A plastic case similar to those sold by Radio Shack can be used for housing the unit, and a piece of #14 gauge, or heavier, bare copper wire may be used for the touch element. The wire should be bent into a hook shape for hanging on

the doorknob. R1, the sensitivity adjustment resistor, should be a panel-mount-type potentiometer instead of a trimpot mounted on the perfboard, as this will greatly ease adjustment when the alarm is to be used.

Test and Adjustment

The alarm may be tested for proper operation without hanging it on a doorknob. To do so, first adjust sensitivity control R1 for minimum resistance and then apply power. If you have included the delay circuit, you will have to wait approximately thirty or forty seconds before the alarm will arm itself. Now, while touching the pickup element, adjust R1 towards maximum resistance. At some point, while adjusting R1, the alarm will trigger and go off. To reset the alarm, momentarily depress S2. I must mention here that depressing S2 will only reset the alarm; it will not activate the delay. To reactivate the delay, power must be momentarily interrupted by opening and closing S1. Also, after the sensitivity has been increased, the alarm will sound when power is applied. To prevent this, hold down the reset button while applying power. R1 will have to be readjusted when the alarm is hung on the doorknob, as this changes the sensitivity of the input circuit.

Summary

This alarm would probably be most useful to those living in apartments and could easily be thrown into a suitcase for use in motel or hotel rooms when away on trips. But, wherever used, it will provide a sense of security otherwise unknown.

If you have any questions or comments concerning the operation of the alarm, an SASE to me will bring a prompt reply. ■

Get the DX Edge

There are ways to stand out in the pileups for Spanish-speaking stations. One is to speak their language.

Do your present operating activities make your heart beat faster and your nerves tingle from excitement? If not, you could be in a bit of a rut.

Novices seldom have this problem, but many other hams later find that they need to try other avenues of their hobby. Operating an exotic mode like slow-scan television is one approach; another is chasing certificates. My choice is talking with hams of the Spanish-speaking countries.

Why try the Spanish language? For openers, the Spanish-speaking people are among the most gracious people in the world and are very patient with beginners speaking their language. They bend over backwards to overlook errors and always enthusiastically encourage beginners. A knowledge of Spanish gives you an edge in working Mexico, Central America, South America, the West Indies, Spain, the Canary Islands, the Balearic Islands, and the North African cities of Ceuta and Melilla. (These are Spanish enclaves on the coast of Morocco.) And that constitutes a lot of DX!

Spanish is a good beginner's language. It often is pronounced nearly as it is spelled. For example, the F sound is always spelled with an F. It does not have spelling nightmares as does English, in which an F sound can be represented by gh (in enough) or by ph (in phone). Another advantage is that when the other operator hears you attempting to use his language, he often will try his hand at speaking English. It's a bit like fishing—you throw out your lure in the form of spoken Spanish and reel in your catch in the form of a contact in English.

Most hams begin their hobby as Novices working other Novices, and this is a good way to begin using Spanish. The Novices from Spain are licensed to use voice communication from 29,000 kHz to 29,100 kHz. Their callsigns begin with EC instead of EA. During the fall, spring, and winter months, they can often be worked from about 1200 UTC until 2000 UTC in the midwestern United States.

Spanish Novices exhibit that universal trait of Novices everywhere—enthusiasm. A contact with them is not the usual one of "You are 5 × 9 in Madrid, QSL via the bureau and QRZed." They usually will answer with an excited tone in their voices, often with a rapidly spoken "OK, OK, OK!" For many this may be their first DX contact, and they will QSL direct. Their QSLs are often beautiful postcards of their QTH, with the technical information stamped on the back. I always look forward to checking my mail for a new postcard with interesting stamps. They may also send a red ribbon with a yellow center stripe, which represents the Spanish flag.

After working a stateside Novice station, you always enjoy working that same station again when he has upgraded. You will get an even bigger kick doing this with Spanish Novices. One day I called CQ in Spanish on 15 meters and was answered by an EA whom I had worked several months earlier when he was a Novice EC. He remembered me, described my QSL card, and noted what a great pleasure it was to have another contact. You don't get that from a DX pileup!

If you have ever wanted to be a DX station but you live in Chicago or Los Angeles or Detroit or operate low power with something less than a gain antenna, take heart; the Spanish Novices consider

Reader Service for facing page ✓5 →

you to be good DX. I know, because one day after returning home from work I found 10 meters to be open into Spain. I answered a CQ in Spanish, and at the end of the contact I had a new experience: Several Spanish stations shouted my callsign! It was a bit nerve-wracking at first, but I got used to being a hotly sought-after DX station. In one hour I worked about a dozen stations, exchanging complete QSL information, and could have worked more, but the band went dead.

If you enjoyed the challenge of working all 50 states in the US, why not try your luck at working all 50 provinces in Spain? When you have all 50 confirmed, you can apply to the U.R.E., Box 220, Madrid, Spain, for a certificate. If you are having a hard time working the EA9s from the North African Spanish enclaves of Melilla and Ceuta, you might try the EC9s in the Novice bands. There also are quite a few EC6s from the Balearic Islands and EC8s from the Canary Islands. They might even consider you to be DX, especially if you know Spanish.

Incidentally, if you are a person with a bit of imagination, get an atlas and a guide book or travel book about Spain and look up the cities in Spain that you work. It's like an inexpensive vacation. I use the guidebook by Baedeker which lists the main cities in alphabetical order with color pictures, a short description, history, and a list of fiestas and events. It's a bit expensive at about $11.00. Rand-McNally has a good pocket-size one for about $4.00. Both are available at most bookstores.

Also on the 10-meter band from 28,900 kHz to 29,000 kHz are the Novices and Intermediates from Argentina, and they are allowed to use voice communication here. They can be worked almost anytime that 10 meters is open, and their operating hours are close to ours, since their local time is 3 hours behind UTC. The calls of Argentine Novices begin with LU, as do the calls of higher-licensed Argentine stations.

You can start working these Spanish-speaking stations with just a few basic words and phrases. First, most consonants are pronounced similar to ours. The vowels are pronounced clearly and distinctly. Pronounce A like the English *ah*, E like our *ay* in *say*, I like the i in *machine*, O like our *oh*, and U like oo in *cool*.

You already know the Q signals and have only to pronounce them as letters of the Spanish alphabet. QSB is pronounced *coo-aysay-bay*; QSL is *coo-aysay-aylay*; QTH is *coo-tay-ahchay*; QRM is *coo-airray-aymay*; QRA (which means "my name is ___") is *coo-airray-ah*.

Know the numerals 0 to 9 and a few useful phrases (see box). A typical contact might go thus: *Esta es W1AW*, this is W1AW; *gracias*, thanks; *su reporte es cinco nueve*, your report is 59; *QRA Hiram*, name is Hiram; *hay QRM*, there is QRM; *QTH Newington, estado de Connecticut*, location is Newington, state of Connecticut; *habla despacio*, speak slowly; *cambio*, over.

This article touches on only the essentials, and its main purpose is to promote interest in working Spanish-speaking stations. Several aids have appeared recently which are shortcuts to a proficiency in using Spanish on the ham bands. *The Radio Amateur's Conversation Guide* by OH1BR and OH2BAD lists, in eight languages, 147 sentences relating to ham talk, and this is available from Transelectro-America, 2301 Canehill Avenue, Long Beach CA 90815. It has a dictionary listing ham-related words, also in eight languages. For example, if you need to find the Spanish phrase for "frequency shift keying," just look it up in this dictionary.

The book has quite a few spelling mistakes, at least in the Spanish section, and is a bit expensive, but it has some interesting cartoons and the dictionary is unique. Tapes in each language are available for $6.00 each, and buying the Spanish one certainly would be a wise investment. Another tape, "Hola CQ" is available with 15 pages of text from the ARRL for $7.00.

The basic goal is not to learn a lot of grammar and a large general vocabulary. When you are on the air, you likely will not be asking a Spanish repairman the cost of a new carburetor for your car, but you would be informing a Spanish-speaking operator that his modulation is good or bad. Learn a little grammar and a small specialized vocabulary and have a good time.

I did study Spanish about 15 years ago for two years and had some success with the written language, but the spoken language would drive me to find the nearest interpreter for anything more complex than "Buenos Dias." I have been using Spanish over the air for over a year now, and with the help of the conversation guide, I can make it through a contact even if I don't understand everything. Much like learning the code, practicing Spanish makes perfect.

The FCC says one of the reasons that the Amateur Radio Service exists is "the continuation and extension of the amateur's unique ability to enhance international goodwill." I think I know what these words mean. One day after eight hours of hassles and harassments at work, I came home and turned on the rig. I made contact with a Novice from Argentina. We made the usual exchanges of name, QTH, and reports. Then I heard some words that I had not heard at work that day which translated into: "Magnificent, I congratulate you for your very good Spanish!"—the first kind words I had heard all day! And I knew that my goodwill had certainly been enhanced that day.

I hope that your goodwill also will be enhanced as a result of talking with Spanish-speaking countries; besides, it's a lot of fun! *Siete tres!* ■

Power-Line Protection: The Weak Link

Solid-state equipment may be extremely reliable, but just microseconds of overvoltage can change that.

Most amateurs take precautions to prevent damage to their homes and equipment from lightning strikes or near strikes on their antennas or towers. Few of them, however, are as well protected from the other common source of problems—power-line surges. These surges frequently result from strikes on power lines and can cause transients of thousands of volts in ordinary 110/220 household systems in the vicinity of the strike.

Pulling the plug on ham equipment during electrical storms has been one way of solving the problem. However, many hams participate in weather nets during severe storms, so pulling the plug on the rig is not the answer. Also, pulling the plug on everything in the house is a difficult way to live. It's much better to put one of the new transient voltage suppressors on your line, relax, and know you are safe from anything except a direct hit.

Most amateurs who grew up in the vacuum-tube era have paid little attention to transients as most electrical and electro-mechanical devices with tubes can withstand large instantaneous overloads with little apparent damage.

The advent of the solid-state age has brought with it a new set of problems. Solid-state equipment is extremely vulnerable to transients. Voltage surges above rated values, even though only microseconds in duration, will destroy this circuitry. Many baffling failures of solid-state equipment, when thoroughly investigated, have been found to be due to transients which no one knew existed.

Fortunately, the technology that brought us these solid-state wonders has also brought us protective devices to compensate for their weakness. The devices, called transient or surge protectors, are basically metal-oxide varistors. Recent improvements in composition and fabrication have allowed the development of a whole family of devices for overvoltage protection.

Surge protectors designed for home electrical systems are now available at most electrical supply houses. The units are intended for use in service-entrance boxes and fit into standard knockout holes. They will provide protection for household circuits against surges capable of damaging common electrical equipment.

The protection unit is connected across the line as shown in Fig. 1. Connection is simple; anyone with a basic understanding of electricity can connect it. Open the main breakers when installing the unit. The protector remains in a non-conducting state under normal conditions. Voltages exceeding 175 V cause the unit to conduct, diverting the transients to ground. The action is somewhat similar to that of the common zener diode. The unit returns to a non-conducting state when the voltage returns to a level below its critical breakdown value.

Not only ham equipment, but also most of the new things we buy for our homes, from clocks to ranges, now include solid-state devices. So a suppressor on your incoming line could save more than just your ham gear.

Manufacturers recommend placing a protection unit as far ahead of your household wiring as possible for maximum protection. However, your local power company may have ideas on placement. Mine would not allow placing the protector ahead of the main breakers. You can argue with them, but camp lanterns are tiring and they won't run our refrigerator or my ham rig. So, do what they say. Connected this way, a severe surge could wipe out the main breakers but the individual circuits are still protected. It's a small investment in peace of mind. ■

Higher Voltage, Less Weight

A voltage quadrupler that weighs ounces? You bet—and cheap surplus capacitors make it possible.

Voltage doubler, tripler, and quadrupler circuits were in the books way back in the days of vacuum-tube rectifiers. But with the vacuum tube, we had problems of separate insulated filament supplies and/or limited insulation between an indirectly-heated cathode and its filament. Solid-state diodes took care of this problem very neatly, but the day of the high-capacity capacitor for a reasonable price had not yet arrived. So, the admonition always was, "This is a good circuit for a very limited load. The voltage vs. load characteristic is terrible!"

Well, all of the above shortcomings have been pretty well overcome. Six-hundred-uF, 360-working-volt photoflash capacitors have appeared on the market recently at various bargain prices. I was able to buy 10 for $7.50.

Now we have all of the necessary ammunition. Let's see what we can do with it. First of all, in the interests of safety, we need a circuit where the ground side of the ac line is also the negative terminal to our power supply, if there is to be no transformer. This rules out the full-wave doubler and any quadrupler that might be derived from it. The full-wave doubler has been a favorite for converting a 700-volt TV transformer to 1500 volts dc. With a transformer, you can earth ground at any point you want, but with just the ac line, one side already is grounded. A floating ground in electronic gear is a very dubious thing. It's possible to tie all negative returns together, insulated from a grounded chassis, and then go to the chassis through a by-pass capacitor. There have been some commercial electronic devices that have done this, generally with a plastic cabinet surrounding the unit. *Let's not do this!*

Fig. 1 (a) shows the standard-voltage multiplier circuit. At the risk of duplicating most handbooks, the first negative half cycle on the hot side charges C1 to peak voltage (in the case of 120-volt line, $E = 120 \times \sqrt{2} = 170$ volts). On positive half cycle, the line is +170 in series with C1, which makes 2E, thus charging C2 to 2E. The next half-cycle ground side is +E with respect to the hot side. This is in series with C2 and the third diode, thus charging C3 to 3E. The next half-cycle hot side is +E with respect to ground and in series with C3 to make 4E, and C4 is charged to 4E, etc. This can go on indefinitely as long as no current is drawn from the supply, but if the capacitors are large enough, you can get close to the no-load value with considerable load.

Now, it will be noted that we need capacitors with increasing voltage values. For a quadrupler, for instance, we need a capacitor capable of withstanding about $170 \times 4 = 680$ volts. This will take two of the aforementioned 360-volt caps in series. So, let's use C2 a second time instead. Just return from C4 to the plus side of C2 instead of to ground. Also, return C3 to the plus side of C1 instead of to the hot side of the line. With these modifications we get Fig. 1 (b), and no capacitor has more than 2E across it. 2E = 340 volts, and the working voltage of the caps is 360, so we are safe. Our voltage regulation may not be quite so good with this modification, but it is still better than many people would have guessed.

Fig. 2 shows the charac-

AT LAST!

This service will be available nationally. Lab tested & time proven modifications professionally installed in your amateur Handy-Talkie 2M, 220, 440, MH2 transceiver.

HAVE ALL PL TONES AVAILABLE AT YOUR FINGER TIPS

Outboard the dip switch! Have it neatly inlayed into the back cover of your Handy-Talkie making all 32 PL Tones Selectable at a moment's notice.

$25 Got your own PL? Send it to us with your Handy-Talkie unit and we do the professional installation for you.

$55 We will install a new PL and inlay the dip switch into the back cover of your Handy-Talkie ready to operate.

Send us your Handy-Talkie unit and a check or money order plus $3.50 for shipping and handling payable to **A&W PRODUCTIONS, INC.**

For **TEMPO** units the dip switch is inlayed into the Push-to-Talk bar. The **TEMPO S-15** will have the dip switch inlayed into the back cover.

$45 We will install a **NEW BATTERY BEATER** in your **TEMPO S-1, S-2, S-4, S-5 READY** to operate. Your New Battery Beater will use the same jack as the charger with no new holes and regulation circuits built into unit. Comes with Cigar Lighter Adapter with internal fuse.

CONTACT A&W PRODUCTIONS FOR SPECIAL MODIFICATIONS YOU MAY WANT TO HAVE DONE. WE SPECIALIZE IN THE TEMPO HANDY-TALKIES.

ALL WORK GUARANTEED FOR 30 DAYS. SEND YOUR HANDY-TALKIE AND A CHECK OR MONEY ORDER TO:

teristics of voltage vs. load for a doubler, a quadrupler, times six, and times eight. The quadrupler seems most interesting. This voltage would be enough for a sizable linear and, with speech peaks to half an Amp, might not go much below 600 volts. The times eight supply would deliver about a quarter of an Amp at 1000 volts. This might fit someone's needs. This is a power supply weighed in ounces!

Now let's look at a few practical aspects. How do you get this thing fired up? I used 1000-piv, 2.5-Amp diodes because I had them. Then I brought the voltage up slowly with a variac to run the tests. Once you are up to line voltage you are in business, but don't throw it on the line point blank or the surge current of the capacitors will wipe out your diodes.

On a second power supply, a quadrupler, I put 250 Ohms in series to charge up the capacitors and then shorted it out with a switch before putting any signal into the linear amplifier I used for a load. But you *must* remember to open that switch before you turn on the power the next time! A 30-second thermal time delay could be installed to take care of this.

A second must is that you must carefully polarize your power plug. If you have three-pronged plugs in your wall, determine which pin is hot and which is cold. An NE51 can be made into a tester very easily. Solder a short piece of hookup wire to the center contact. Hold the brass base in your fingers and insert the wire into one pin of the wall plug. If the neon lights, that is the hot side. (Of course, a light bulb wired between one pin and the earth ground will tell you the same thing.)

The same procedure goes for two-pin plugs, but you *must* mark them and always plug in in the proper way. If you are going to plug the supply in in several places, you need to check each plug. Journeymen electricians have been known to get the hot and cold wires reversed even in modern three-pin plugs.

The advantages of the transformerless power supply are obvious. In addition to the savings in bulk and weight, you can mount the whole thing on a piece of perfboard and put it inside the unit you wish to use it with—600 volts for something like $5.

If you live in ZL-land or some country that has two-wire service with 240 volts to ground, a voltage quadrupler has possibilities for something pretty big. ■

Make Room for More Agc

Automatic gain control is useful in many applications. With this simple circuit, you'll never have to be without it.

What with avc, alc, agc, etc., we have some form of automatic control over the gain or output of a lot of circuits. Still, there is a place where there's room for some more automatic gain control. That's in a speaker amplifier. There are many times when we use a small speaker amplifier to up the level of an output designed for headphones, where the amplifier is used to monitor two or more circuits, or where the amplifier is used with some special equipment that has large output variations. In these cases, manual gain can have a drawback or two—forgetting we've cranked the volume down or up, missing something, or shocking our eardrums.

Here's a circuit for a small speaker amplifier with automatic gain control that is both simple and flexible. It's simple because it uses one IC, one FET, a couple of diodes, and a few standard resistors and capacitors, with no complicated setup adjustments. It's flexible because it allows for a wide range of release times set only by a resistor and/or capacitor.

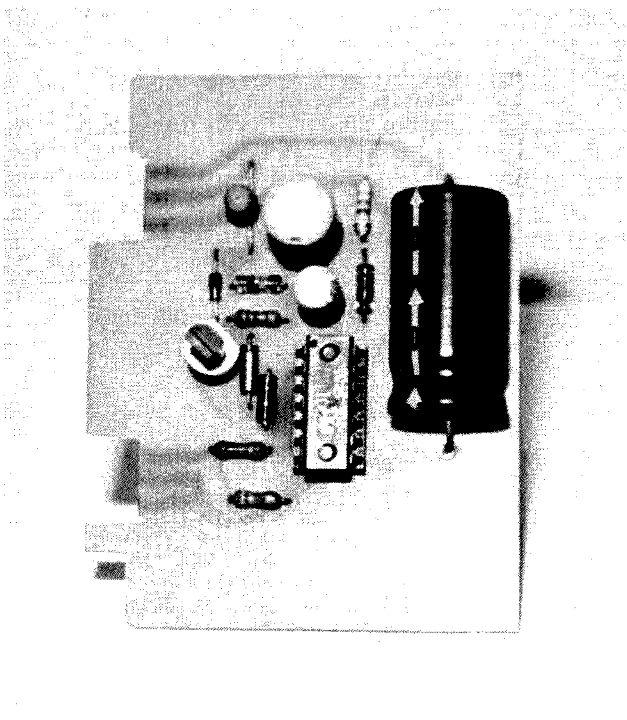

Fig. 1. This photo shows the simplicity of the speaker amplifier to be used in a modular receiver.

There are two primary methods to automatically control the output level of an amplifier stage. One is to vary the gain of the amplifier (remember the 6L7 tube); the other is to operate the amplifier at normal gain and introduce a variable loss pad at its input or output. The latter is the simplest when many of the parts may be coming from the junk box. In the unit shown, the loss pad is at the input to the amplifier where the signal level is small. This reduces the distortion introduced by the variable impedance leg of the pad—in this case, an FET. Distortion is further reduced by applying a proportional signal through the FET to the inverting input of the amplifier.

Layout is not too important. It should be remembered that the LM-380 is a high-gain IC and the input wires should be as short as possible and not be run in close proximity to the output circuitry. Most P-channel JFETs will work in this design—some better than others. My first grab in the junk box got a T-1812, so it was used for the performance measurements. Similar performance was obtained with several other types that were tried. JFETs with pinch-offs that are considerably removed from those of the T-1812 might require another value for the zener diode.

Note that diode D1 is germanium and D2 is silicon. Germanium is used at D1 because it requires less voltage to conduct, increasing the first step voltage of the voltage doubler signal rectifier. This same characteristic would be desirable for D2, the voltage doubler's second stage, but even more we need a diode with high reverse resistance. In order to get a release time of about 4 seconds, we need a large RC combination. To keep the attack time short, C should be less than 3 uF, which means an R value of about 2 megohms. The reverse resistance of D2 should be some 5 to 10 times this value. Almost any silicon signal diode such as the 1N914 or 1N4148 will meet this criterion.

Figs. 3, 4, and 5 show the

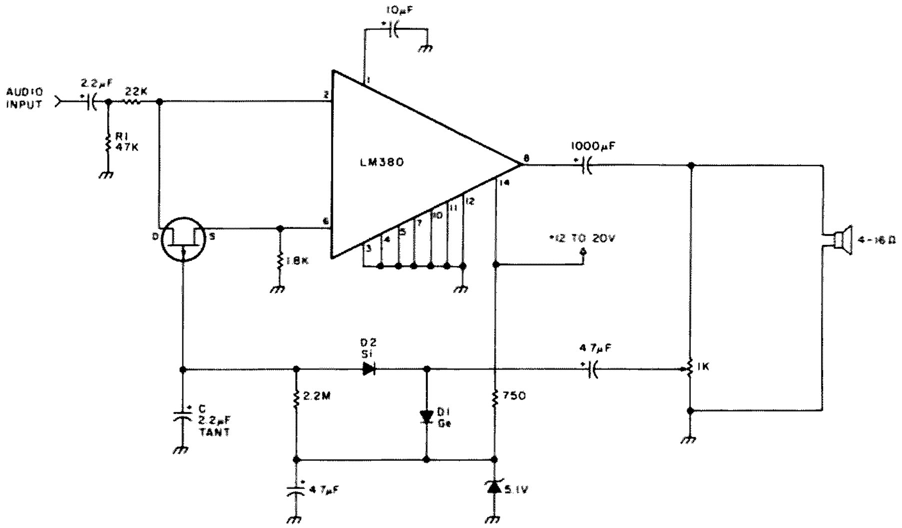

Fig. 2. Schematic.

frequency response, compression characteristics, and distortion at various levels of compression. These were all measured at 125 mW output, which seemed to drive a 6-inch-high efficiency speaker at the volume I wanted in my shack.

The potentiometer sets the output level at which compression starts. When its arm is at the ground end, the compression circuit is, in effect, disabled. Although no input control is shown, one could be inserted by replacing R1 with a 50k pot to permit monitoring a variety of levels greater than the compression range of the amplifier. If the output is too much with the FET you're using, a resistor in series with the speaker is the simplest way to bring it into line. It will affect the fidelity a little, but not enough to bother in communications service. The resistor value can best be determined experimentally and probably will be between 4.7 and 100 Ohms. A variable speaker pad also would work well.

There are many reasons why it pays to build this compression circuit into almost any audio amplifier that uses an LM-380. For one, it takes nothing away from its normal operation—when the arm of the pot is at the ground end, you have a standard amplifier. The small amount of time, money, and space that it takes to add this circuit gives big rewards in keeping the output at a consistent, comfortable level.

Try it. You'll like it. ■

You Can Troubleshoot Mobile Noise

K5CA tells what to do when a signal is 5-7 and the noise is 5-9.

Over the years ham radio interests, along with methods and equipment, have continued to evolve. Early in ham radio history the desire to convert heavy fixed-station receiving and transmitting gear to use in vehicles appeared, resulting in the first "mobile" operations. This modification process was difficult enough considering weight, size, and power requirements, but along with these came a whole new realm of problems.

Fixed-station operation has always had problems with the noise and interfering signal environments. Great as these problems have been, at least they are generally consistent and geographically contained. Mobile operation, however, not only is affected by all these noise problems, but also adds the new dimensions of vehicle-generated noise and noise from changing locations. Although today we have developed much more reliable, more sophisticated, and easier-to-integrate equipment for mobile use, the old noise problem continues.

Unfortunately, rf noise comes from many sources and when in motion, practically all of these come into play at one time or another. To be honest, there's little that can be done about many of the noises encountered—high-noise power lines, ignition radiation from other vehicles, spurious signals from other transmitters, etc. In some of these cases, a good-quality noise blanker provides help. In others, patience and operating skill are the only solution. By the way, although the mobile high-frequency systems (SSB, CW, etc.) have classically been the ones to be the most bothered by noise, the "noise-free" VHF/FM systems so popular today also have their share of noise problems. This article attempts to provide a summary of noise conditions that any of our radio equipment is subjected to in mobile use and to provide a related approach to minimize the noise effects.

There is a class of noise which is very disturbing in mobile operation and for which there is some reason-

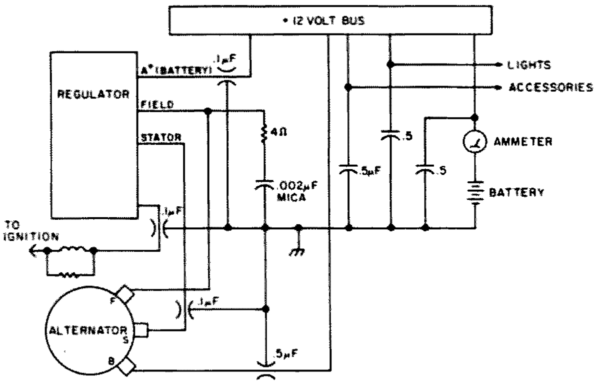

Fig. 1. Electrical power system.

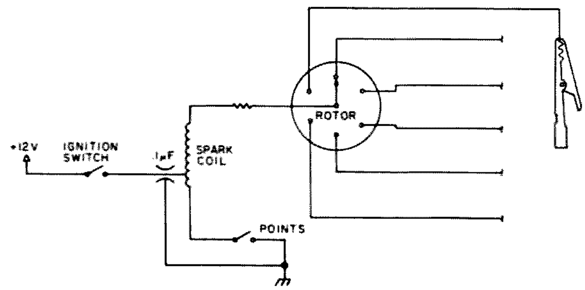

Fig. 2. Ignition system.

able solution. This class of noise is that generated within the vehicle where the station is installed. Right off the top, even using the best equipment and techniques, some noise may persist. However, to wage a solid battle against the aggravation of vehicle noise, the approach outlined here may be of real value. This approach is not new; many publications have presented such information in the past, and several were consulted in putting this article together.

The secret to lowering rf vehicular noise levels is:

- Identify the noise and the noise source.
- Eliminate the noise at the source if at all possible.
- Minimize noise-conducting and/or radiating paths.

When working on noise problems, you may find several distinct noises present. Work on these starting with the loudest/strongest first, then proceed downward through the list by next strongest one at a time. The following approach may help to identify the source of each noise.

Perform a vehicle-in-motion test. Run the vehicle in an area large enough to maneuver, but away from fixed noise sources (buildings, power lines, etc.).

Run the auto at moderate speeds; while moving, place the transmission in neutral and turn the ignition switch to accessory. If the noise goes away as you coast, it's most likely coming from the ignition system. (Be careful with this test, especially if you have power steering.) If the noise is a varying-pitch whine and stops with the ignition off, it's probably coming from the alternator. If the noise has a clicking or popping sound without any particular frequency and it disappears with the engine at idle or off, it's probably produced by the voltage regulator. A hash that has some variation with engine speed but doesn't come from the charging regulator indicates you have a Ford (Ford uses an electromechanical instrument regulator which is a notorious noise source).

In normal driving situations, the following noises and related sources may be noticed. While in motion, a sharp popping noise which doesn't seem to vary with engine speed probably comes from "tire static." (This may come and go as the road surface changes.) A rushing noise with an associated popping indicates a general auto high-static condition. This generally occurs when close by a thunderstorm. A jiggly, scraping noise indicates the production of body static caused by metal elements of the vehicle not electrically connected and rubbing together.

In order to put some systematic approach into play to help identify and combat these noises, Table 1 was prepared. In addition, to outline the typical auto electrical system, Figs. 1 and 2 were developed. These schematics indicate the particular components and hookups which may require attention.

Good luck in identifying and eliminating or reducing your particular vehicle noise problem. Keep in mind that although noise is an aggravation for us in mobile operation and the fixes may take some time and effort, the result is well worth it. Happy motoring! ■

Noise Sound	Possible Source	Steps
Popping changing to hash as engine speed increases	Ignition	Use new resistor spark plugs.
		Check all ignition cable for loose or poorly-crimped connections (solder where possible).
		Install resistors in distributor/coil lines and spark-plug lines. Use resistance ignition wires if available.
		As a last resort, install shielded ignition system (kits available, listed in *QST*).
Whine which changes pitch with engine speed	Alternator	Use a 0.1-uF coaxial capacitor in series with the alternator armature (A) lead.
		For "hard" cases, place a parallel tuned trap (with heavy wire) in series with the A lead. Tune to the operating frequency.
Irregular clicking	Regulator	0.1-uF coaxial capacitor in series with battery (B) and armature (A) leads.
		A series .002-uF mica capacitor and a 4-Ohm carbon resistor from the field (F) terminal to ground.
Irregular clicking	Vehicle wiring	0.1 coaxial capacitor in series with battery lead to ammeter; .5-uF coax capacitor in lead to gas gauge; .5-uF coax capacitor in lead to oil signal switch; .5-uF capacitor across headlight and taillight leads and other accessory lines.
Popping noise which changes with road material	Wheel static	Install front wheel hub static discharge springs (from auto parts houses).
Same	Tire static	Inject anti-static powder in tires.
Popping, scratching noise following jolts as the auto moves	Body static	Tighten all screws and bolts.
		Bond major auto elements to each other with heavy braid and lugs (engine, firewall, frame, fenders, hood, exhaust pipe, etc.).
Hashy Fords	Instrument regulator	Replace with 5-volt electronic module regulator.

Table 1. Mobile noise reduction.

Electronics vs. Creepy Crawlers

Build this ultrasonic oscillator and drive pests crazy. Your pet hamster, too.

One thing you will find out when you become interested in electronics or have ham radio as a hobby is that eventually your curiosity will expand to investigating all sorts of electronic devices. This includes accessories for the ham shack, microwave downconverters, radar speed detectors, cable TV gadgets, and other interesting items. This article describes a gadget which has recently appeared on the electronics scene and really caught my attention as something I needed very badly in my ham shack.

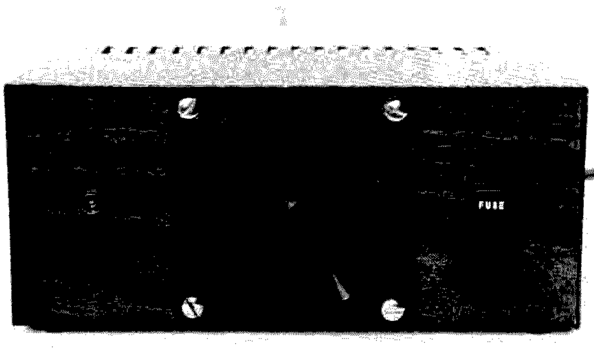
Now, I don't know about your ham shack, but mine is firmly delegated to a room in the basement of my house. The only problem is that since it is at ground level, all sorts of unwanted creepy crawlers invade my shack and take up residence in my ham gear. For many years, pet supply and garden stores have sold all sorts of products to rid a home of those pesky bugs and such. Well, now the electronics industry has taken on the challenge and thinks this is the answer on how to run those bugs out of my ham shack.

Circuit Description and Construction Notes

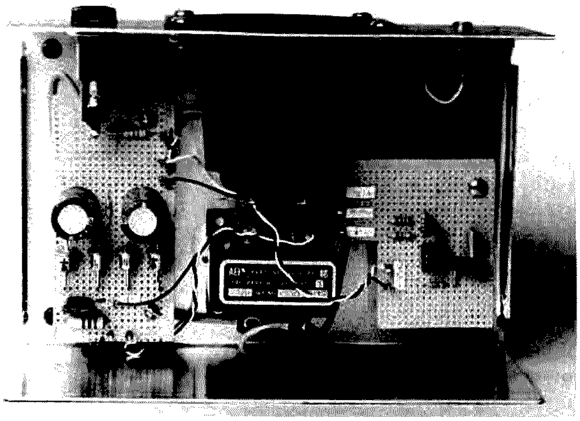
Low-intensity ultrasonic sound waves have been used to repel insects and small rodents. Square waves and pulsed waves have been tested and square waves are reported to be most effective in the 30-45-kHz frequency band. The ultrasonic sound waves are intended to damage the insects' nervous systems. The goal is to drive those creepy crawlers right out of the house. The ultrasonic sound waves are shifted in frequency 60 times per second to cover all of the communication frequencies of the most common pests (how about that—legal jamming!).

The ultrasonic sound emitted by the unit is above the hearing range of people, dogs, cats, and birds. It is reported as not affecting plants, TVs, and radios, but will bother gerbils, ham-

Photos by Betty Hutton



Front view of unit.



Component layout for the ultrasonic bug-chaser.

sters, and other pet rodents.

Several commercial models of bug-chasers have recently appeared on the market (see box). The schematic diagram shown is typical of such units and is designed to generate a swept square wave from 30 to 45 kHz. The LM555 IC is wired as an ultrasonic oscillator driving a piezoelectric speaker of the hi-fi super-tweeter type. The output of the oscillator is swept by a 60-Hz signal from the ac input of the bridge rectifier. The LED acts as a pilot light to let you know the power is on, as the only noise you will hear when this unit is running is a slight buzzing noise coming from the speaker.

An oscilloscope is necessary to observe the square-wave signal on pin 3 of the LM555 oscillator. My unit is built in a cabinet 3-1/2" × 7-1/8" × 5-11/16" (Radio Shack #270-269). The speaker is a 3.5-inch Piezo Super Horn (Radio Shack #40-1381). The oscillator and power supply were built on two small perfboards and bolted on metal standoffs to the chassis floor. No effort was made to design a PC board or to miniaturize the design. The front, bottom, and rear of the cabinet were covered with simulated wood-grain shelf paper to improve the appearance of the unit.

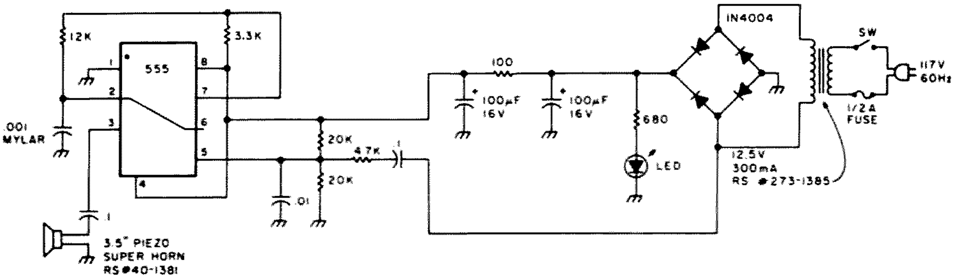


Fig. 1. Ultrasonic bug-chaser schematic.

Operation

I set my unit in one corner of my ham shack facing out into the room so that the ultrasonic sound waves would fill the room by bouncing off the walls, floor, and ceiling. Things like curtains, rugs, and upholstered furniture will absorb the sound waves. You should expect it to take several weeks before the full effect of the irritating ultrasonic sound waves will get to the bugs. I have had several visitors in the shack and they soon note the slight buzzing noise coming from that strange-looking box on the shelf. When told what it is, they unanimously say they want to build one for their own ham shack. Try it; the only thing you will have to lose is those pesky creepy crawlers. ■

Slimming and Trimming the R-1000

In crowded conditions, the 6-kHz filter may not cut the QRM. Here's the way out.

Milton Ertelt 5Z4CL/K5PAW
PO Box 30514
Nairobi, Kenya

Living overseas and not being able to have at your disposal the type of news and entertainment available in the United States causes many to try shortwave listening to receive news features from home. Our family's habit is to listen to broadcasts of the Voice of America and the Armed Forces Radio and Television Service (AFRTS) in addition to broadcasts from other countries for news and information about current events in the States.

Being in East Africa and tuning the shortwave bands, one quickly notices that Africa is the focal point for hundreds of powerful shortwave broadcasts which result in crowded band conditions and interference between rival programming. Sometimes it is almost impossible to separate from pileups weaker signals like AFRTS not normally beamed to East Africa.

With this background, I purchased the Kenwood R-1000 communications receiver for shortwave listening. The R-1000 is an advanced general-coverage receiver providing continuous coverage from 200 kHz to 30.0 MHz. It features a PLL synthesizer and a digital display for both frequency readout and the built-in clock and timer. It also includes an rf attenuator, a noise blanker, and capabilities for receiving LSB/CW, USB, and AM. For AM, either ceramic filters for 6-kHz or 12-kHz bandwidth are selectable for AM-narrow or AM-wide reception.

Crowded band conditions here in East Africa preclude the use of the 12-kHz filter; the 6-kHz filter is sufficiently wide for good fidelity for shortwave music programs. However, a narrower bandwidth is required for many AM situations, and it is to this end that circuit changes were made.

The plan is to utilize the 2.7-kHz SSB ceramic filter for both the SSB and AM-narrow modes, while the 12-kHz filter normally used for the AM-wide mode is replaced by the 6-kHz AM-narrow filter. The 12-kHz filter will be left on the receiver circuit board, but will not be used. These changes can be made by the addition of one silicon diode (1N914 type) and one wire and the removal of two existing wires. These changes can be accomplished in less time than it takes to explain. No holes are drilled, so the R-1000 can be returned to its original configuration at any time.

Here, then, is a step-by-step record of these changes:

1. First, remove both the top and bottom covers from the receiver. The speaker leads can be easily slipped off the speaker terminals.
2. Remove 2 wires, white/brown and white, from terminal #1 of the AMW mode switch, and tie these leads off, taping the ends to prevent shorts. Terminal numbering (on the Mode switch) is derived from the R-1000 Service Manual and is not clearly marked on the switches themselves. However, terminal #1 on the

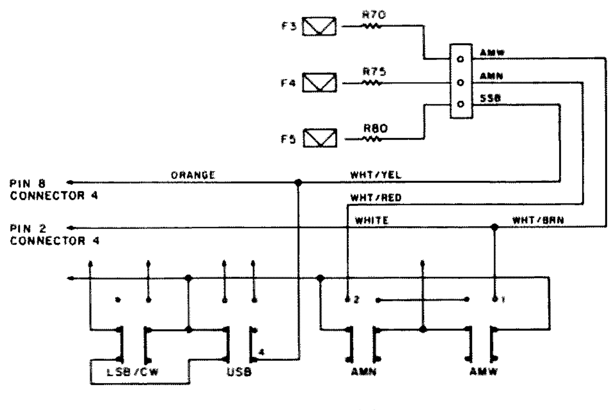

Fig. 1. Before modification.

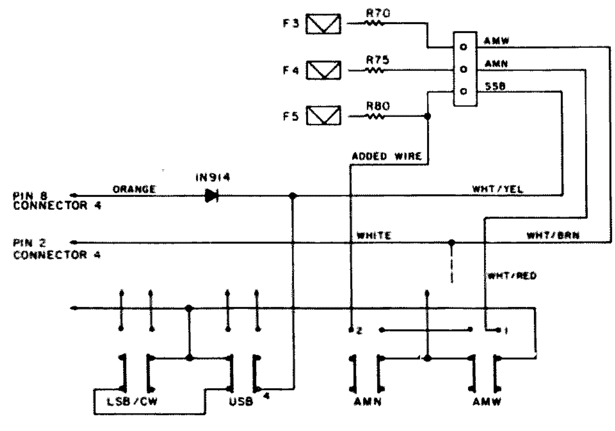

Fig. 2. After modification.

AMW mode switch is the one to which the wire pairs white/brown and white are terminated.

3. Remove the white/red wire from terminal #2 of the AMN mode switch and solder to terminal #1 of the AMW mode switch. Again, identify terminal #2 as the one to which the white/red is terminated.

4. Add a wire from terminal #2 of the AMN mode switch now vacant as a result of step 3 above, and dress it near the vfo case, running it through the slot formed between the vfo case and the receiver circuit board to the top side of the chassis. Connect this new wire to resistor R80. The connection should be made on the lead of R80 nearest to connector #3 (see Fig. 3). There should be enough room between the surface of the circuit board and the insulated portion of R80 to make the solder connection.

5. On the bottom side of the receiver, locate, within a bundle of wires running from the Mode switch near the Band (megahertz) switch, the orange wire running between terminal #4 of the USB mode switch (this is the only orange wire on the USB Mode switch). Then find terminal #8 of connector #4 on the top of the chassis. Pull the orange wire away from the wire bundle at a point near the Band (megahertz) switch and cut the wire at a point just behind the Band (megahertz) switch. Strip about ¼" of insulation from both ends of this wire and solder a 1N914 or equivalent diode between the two ends of the orange wire. The cathode should be closest to the USB Mode switch and the anode facing terminal #8 of connector #4 (see Fig. 2).

6. Replace the leads on the terminal of the speaker and install the top and bottom covers of the receiver.

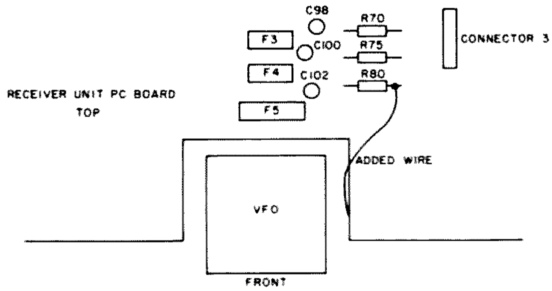

Fig. 3. Receiver unit PC board (top view).

Pressing the AMW position on the Mode switch now selects the 6-kHz bandwidth filter for AM-wide reception. Pressing the AMN position selects the 2.7-kHz bandwidth filter for AM-narrow reception, while the SSB position remains as before.

The end result is a receiver with bandwidth sufficiently wide for good fidelity during listening periods when interference is light. During periods of high interference or in crowded band conditions, the bandwidth of the new AM-narrow mode is extremely sharp, providing an increased ability to separate closely bunched signals. The SSB operation of the receiver is unaffected by these changes.

There are other ways to accomplish the same modification. One could purchase from Kenwood an additional SSB ceramic filter and substitute it for the currently installed AM-narrow filter. But this would be more expensive, and, I believe, more work. These changes improve the operation of an already fine piece of radio equipment. ■

Add a Touch of Class to CB Conversions

Converting a Hy-Gain board to 10 meters is only half the story. Try adding a digital readout and scanning capability. . .

Have you been bitten by the ten-meter FM bug? Do those Hy-Gain CB boards look interesting? Here is your chance to do a little bit of building and have a lot of fun. Since the actual rf conversion of the Hy-Gain boards has been well described in past *73 Magazines*,[1] I will only deal with this digital-scanning frequency selector.

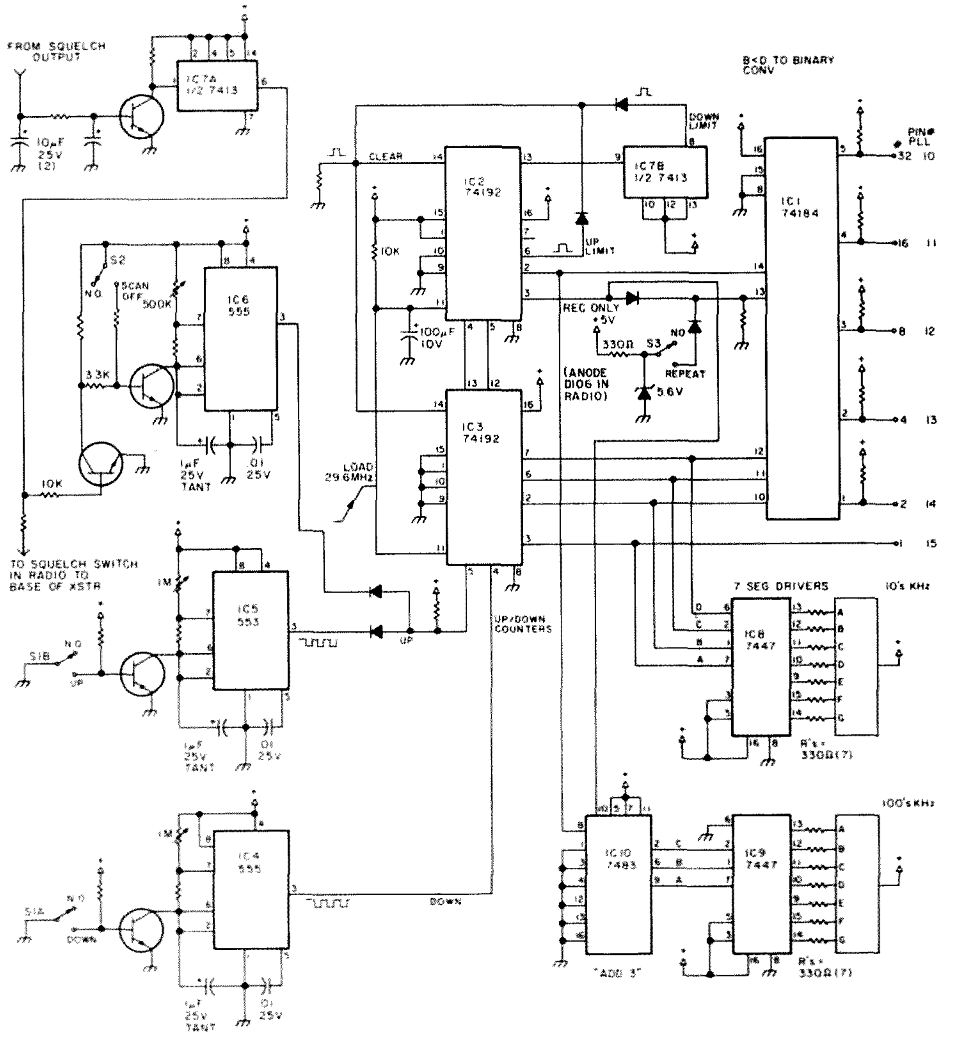

Fig. 1. All transistors—2N3904. All unmarked resistors are 1k Ohms. All + are 5 volts. All diodes—1N4148.

This circuit will give you direct frequency readout. Example: 60 = 29.60 MHz, and so on. There are 40 channels available at 10-kHz increments with a repeater offset for 20 of these channels. A squelch-operated scanner allows you to search the band without lifting a finger.

The crystal in the radio which is 11.8066 MHz has to be changed to 12.69166 MHz. This crystal can be obtained from Jan Crystals in Ft. Myers, Florida. Pins 8 and 9 of the PLL-02 have to be tied to plus 5 volts (preload to binary 192). Pin 10 must be separated from pin 9. This is the conversion that differs from the original in the reference. It is important to get a CB board with a 16-pin PLL chip. The ones with 18 pins require changing the chip to a PLL-02 and rewiring.

The best way I found to build this is shown in Fig. 2. I use perfboard with the holes spaced at .1 inches. The parts are not critical, but an LS series IC can be used to reduce current drain. Five volts must be provided and a 7805 IC can be mounted on the TA7205P heat sink on the radio.

Refer to Fig. 1 for the fol-

lowing circuit details. IC1 is a BCD-to-binary converter. The PLL-02 IC in the radio requires a binary code to select the frequency we want. But to make it easier for us to select the frequency, it is converted from BCD. IC2 and IC3 are up/down counters that provide the sequence counting and the memory for the selected frequency. The counters are driven from IC4, IC5, and IC6, which are gated astable multivibrators. IC7a is used as a Schmitt trigger which is driven from the squelch output. A dc signal must be fed to this so that a high level (greater than one volt) will raise up the base of Q120 in the radio, thus squelching the radio. IC8 and IC9 are BCD decoder/drivers for the LED readouts. The pinout of the readouts depends on what type of common anode displays they are. IC10 is a binary adder. This circuit "adds" 3 to any number found at the output of IC2 (0 to 4). This will let the LED display read the operating frequency, not just a channel number. For example, when the outputs of IC2 and IC3 are all zero, the frequency of the radio is 29.30 MHz. But without IC10, the readout would read "00". But with the "3" added, the readout reads "30".

S1a and S1b is a momentary SPDT center-off toggle switch. When the switch is closed in either direction, it turns off the transistor associated with it and this allows the up or down multivibrators to operate. S2, the scan switch, when closed prevents the squelch circuits from starting the IC6 multivibrator, which is used to run the scanning section. The repeat switch, S3, when open does nothing to the radio. But when closed, it will add 100 kHz to the operating frequency on receive only. When the PTT is pushed, the radio will transmit on the displayed frequency. The anode of D106 in the radio provides about 7 volts in receive only, which makes this offset possible. A special note: This offset circuit works only between 29.30-29.39 and 29.50-29.59 MHz. But the repeater inputs are between 29.51 and 29.59 MHz.

Another feature of this circuit is that when the radio is turned on, the frequency will be 29.60 MHz, which is the international simplex calling frequency. This is done by slowly bringing up pin 11 on IC2 and IC3 during power-up.

In closing, I would say that the use of this circuit really adds polish to these converted CB boards. I would like to thank Charlie DeVoe WA2IUJ for building one of these, to show it could be repeated, and for his opinion of its operation.

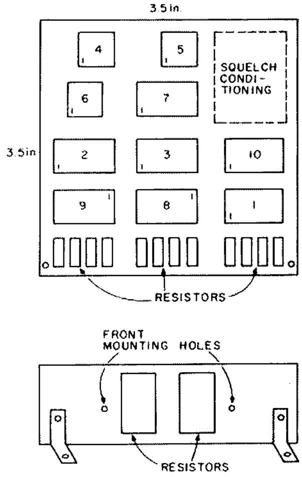

Fig. 2.

I welcome any comments, and I will reply to any questions when an SASE is enclosed. ■

SATELLITES

AMATEUR SATELLITE NEWS

CQ CQ Earthside de STS-9

Well, maybe not, but there is a good chance that amateur radio will be among the astronauts' leisure-time activities aboard STS-9, the ninth flight of NASA's Space Shuttle. Dr. Owen Garriot W5LFL, one of four STS-9 crew members, will operate a small 2-meter FM rig, if all goes according to plan.

Actually, though the proposal has plenty of support from the amateur community, NASA has yet to grant its final approval. W5LFL himself is said to be pushing for the ham activity, and there is plenty of backing from the ARRL, AMSAT, and a number of prominent individual amateurs.

Yet to be decided is the format of the space-borne amateur festivities. A free-for-all operation would likely result in the greatest pileup of all time, complete with frayed nerves and rising tempers. A much more organized method will no doubt evolve—perhaps even a series of one-way transmissions from W5LFL to the thousands of us listening on the ground.

Iskra—Again!

Cosmonauts aboard Russia's Salyut 7 space station have once again launched an amateur satellite. Iskra 3, like its predecessor Iskra 2, was literally tossed out the back door by the cosmonauts, who pushed it through an air lock normally used to jettison refuse. The satellite was launched last November 18 and features a telemetry beacon on 29.583 MHz.

If the example of Iskra 2 is the norm, Iskra 3 may be short-lived. Iskra 2 survived only eight weeks in orbit following its May 17, 1982, launch before plunging back into the atmosphere. And what of the never-mentioned Iskra 1? If the Soviets know, they aren't telling.

Orbital Calendars

Once again this year, Project OSCAR, Inc., has produced an orbital calendar for amateur satellite users. The 1983 version contains the time and longitude of every northbound equatorial crossing for each of the amateur satellites carrying a communications transponder: OSCAR 8, RS5, RS6, RS7, and RS8. It's a real time-saver.

The calendar is available in the USA, Canada, and Mexico for a $10 donation ($12 elsewhere). Send a mailing label, along with your check or money order, to: Project OSCAR, Inc., PO Box 1136, Los Altos CA 94022.

Thanks to *Amateur Satellite Report* and the *W5YI Report* for portions of this month's news.—Jeff DeTray WB8BTH, *73* Staff.

For more information, contact Jim Greer KK2U, 444 Berkshire Road, Ridgewood NJ 07450, or phone (201)-445-2855.

HAM HELP

We are happy to provide Ham Help listings free, on a space-available basis. We are not happy when we have to take time from other duties to decipher cryptic notes scrawled illegibly on dog-eared post cards and odd-sized scraps of paper. Please type or print your request (neatly!), double spaced, on an 8½" × 11" sheet of paper and use upper- and lowercase letters where appropriate. Also, please make a "1" look like a "1," not an "l," which could be an "el" or an "eye," and so on. Hard as it may be to believe, we are not familiar with every piece of equipment manufactured on Earth for the last 50 years! Thanks for your cooperation.

I am looking for manuals and schematics for the Gonset G50 6-meter transceiver and the Conco 611 VHF transceiver, model 861-0611-001. I will pay a reasonable price for the original manuals or photocopies.

Gary Kohtala DA2XF
USAFS-A, Box 1415
APO NY 09458

I would like to find the schematics or technical manual for the VHF Engineering TVX-10 transmitter. I also need the address of VHF Engineering's new parent company. I will pay all copying costs and postage costs.

Lee Robinson WA3HJC
317 Peninsula Dr. #53
Erie PA 16505

I would like a copy of the schematic for the Wang 629 double cassette deck, which is part of the Wang 500/600 programmable calculator.

Dave Overton
1709 W. 30
Austin TX 78703

I need help in identifying some of the components in the Sabtronics #8610B-A 600-MHz, 9-digit counter. I would like to identify 2 chips: one is in the preamp of the prescaler, marked SAB 1009 (also marked J7940) and the other is in the frequency divider and is marked SP 8680B (also marked PS 5 A2). Any information on these ICs would be greatly appreciated.

Patrick Chivington
1476 Grace Ave.
Lakewood OH 44107

I would like to locate a copy of the instruction manuals for the Beckman models 607 and 609 heterodyne converters. These plug-ins extended the frequency range of the Beckman 6100 series counter.

Lyle Pellock W9MWP
2423 Holt St.
Vienna VA 22180

I am forming a nationwide network of motorcycling amateur radio operators. Anyone interested should please check in on 3967 kHz at 0300Z on Thursdays. Send an SASE for more details.

Gary McDuffie AG0N
Route 1 Box 90-A
Bayard NE 69334

I am having difficulties running phone patches with Radio Shack model ET-100T and ET-100 telephones. Rf is causing interference in the telephones. Can anyone give me ideas on how I can clear up the problem?

Everett C. Bollin WA3DVO
8000 Ray Leonard CL
Palmer Park MD 20785

I need a wrench that can remove the spanner nut from the microphone jack of the Kenwood TR-9000. I would also like to increase the scan delay to 10 seconds. Any help would be appreciated.

Curtis R. Olsen WA0NZQ
Box 115
Regent ND 58650

I have a synthesized 2-10-MHz AM-CW transceiver made by Delco. Their designation is Delco 1600. Does anyone know the military designation, or have a manual schematic for the unit?

Gary Cain
1428 Marigold Way
South Bend IN 46617

Wanted: two 60-kHz coil assemblies, part number M42005-1, for the Hammarlund HQ-170. They are marked as T10, T11, and T28 on the schematic.

John Seely WB3EPG
7080 Moore Avenue
Pensacola FL 32511
(904)-456-8096

Has anybody worked out a computer program for converting helical scan transmissions such as weatherfax to information that could be printed on a dot-matrix printer?

Larry J. Clark
c/o USCG Marine Safety Office
Galveston TX 77550

I need information on X- and K-band traffic-control radar units. I would like to build X- and K-band oscillators with an output of about 10 W and any schematics or other information would be greatly appreciated.

A1C Mark LaSalle
Box 2241
APO NY 09130

I am looking for the schematic and manual for the Eico model 249 VTVM. I will pay for any copying costs.

Len TenEycke VE3INK
132 Silverhill Dr.
Islington, Ontario
M9B 3W7 Canada

I am looking for proven modifications or ideas for improving the Ten-Tec Omni D- or C-series units. In exchange, I will provide modification data from my files.

Mickey McDaniel W6FGE
940 Temple St.
San Diego CA 92106

Wanted: bandswitch or individual wafers for the Hallicrafters SX-110 receiver. Suggestions welcome; whole radios considered.

Nick Adams WA4YKV
3009 NE 14th St.
Gainesville FL 32601

I need the manual and voltage specifications for the Heath HG-10 vfo for 2-80 meters, as well as the manuals for the HP500B frequency meter, the Ameco R5 receiver, the Heath FM adapter and the Heath SSB adapter. Finally, does anyone need an "as is" TEK oscilloscope?

Kevin Neal
Route A Box 221A
Flippin AR 72634

I am looking for the schematic to an RME pre-war receiver.

David R. Nadeau
S. 1200 Kelly Ave.
Coeur D'Alene ID 83814

I need assistance in locating the manuals and schematics for the SBE model 34 SSB transceiver and the EMC model 213 tube tester. I will reimburse any expenses.

Jim Seeber
708 Avenue I
Matamoras PA 18336

I am looking for information on software for using the VIC-20 on RTTY and CW. In addition, I would like to know if there is a VIC-20 net or if anyone would be interested in starting one. Just send your suggested time and frequency to me.

Dave Land KD5FX
2512 Bonnie
Ponca City OK 74601

I am interested in receiving the Space-Shuttle communications on 296.8 MHz with a JIL SX-200 AM-FM programmable scanner. Anyone knowing where I can purchase a converter system, please contact me.

Larry Powell
111 Trailview Dr.
Terrell TX 75106

I want to locate the schematic for a Western Electric #2565 HK 3-73 telephone with five incoming lines. I am reassembling the phone with a Western Electric 35AF3A 3-73 pad and a Western Electric 425 terminal block. The telephone will dial out, but it does not ring properly and the feedback monitoring system is dead.

H. Lee Hancock, Jr. W4NXC
301 Forest Hills Blvd.
Naples FL 33942

I need the manuals, either originals or copies, for the Hallicrafters model SX-146 receiver and the companion model HT-46 transmitter. I will gladly pay the costs.

James Hogarth
421 Gruber Rd.
Harleysville PA 19438

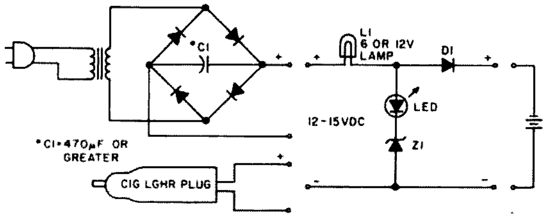
I am looking for the operation and maintenance manual for a Tektronics type L high-gain, fast-rise-time plug-in for a model 545 oscilloscope. I will copy the manual and return it.

Bruce Rahn WB9ANQ
410 Coronado Trail
Enon OH 45323

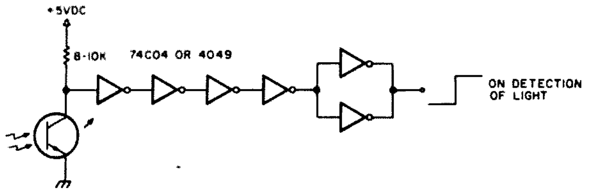
CIRCUITS

Do you have a technique, modification, or easy-to-duplicate circuit that your fellow readers might be interested in? If so, send us a concise description of it (under two pages, double-spaced) and include a clear diagram or schematic if needed.

In exchange for these technical gems, 73 offers you the choice of a book from the Radio Bookshop, *to be sent upon publication. Submit your idea (and book choice) to: Circuits, Editorial Offices, 73* Magazine, *Peterborough NH 03458. Submissions not selected for publication will be returned if an SASE is enclosed.*

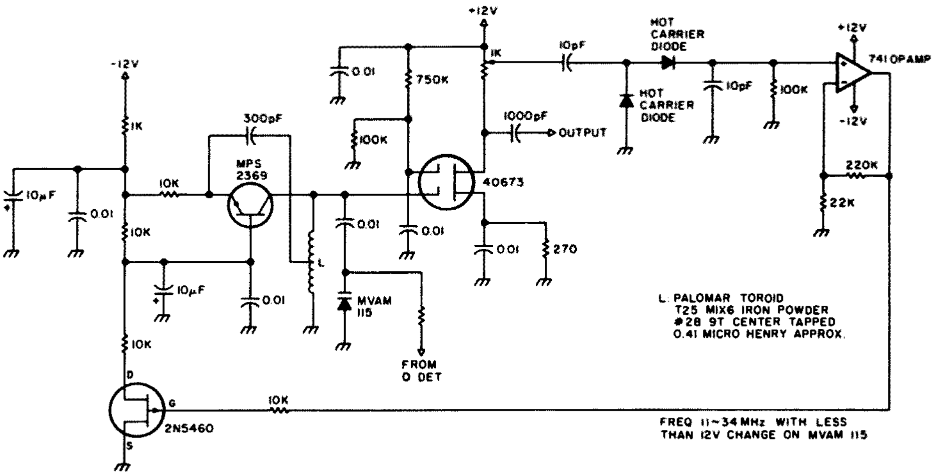


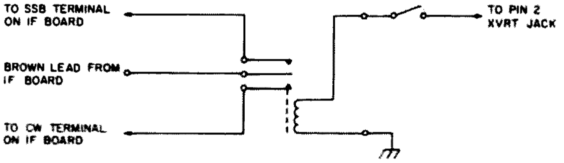
NICAD CHARGER WITH CURRENT AND VOLTAGE LIMITING: Lamp L1 will glow brightly and the LED will be out when the battery is low and being charged, but the LED will be bright and the light bulb dim when the battery is almost ready. L1 should be a light bulb rated for the current you want (usually the battery capacity divided by 10). Diode D1 should be at least 1 A, and Z1 is a 1-W zener diode with a voltage determined by the full-charge battery voltage minus 1.5 V. After the battery is fully charged, the circuit will float it at about battery capacity divided by 100 mA.—Dave Land KD5FX, Ponca City OK.



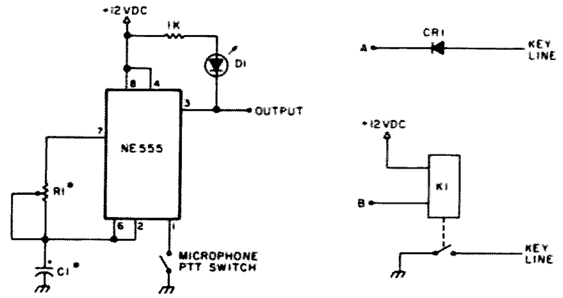
FAST AND RELIABLE PHOTODETECTOR: Using only 3 components, this circuit yields very reliable operation. Gates have been chained together for rapid action and wired in parallel for increased output current. Analog output can be obtained from either the collector of the phototransistor or the output of the first gate. A pot can be substituted for the resistor to adjust the circuit's sensitivity.—Terry Fletcher WA0ITP, Ottumwa IA.

CRYSTAL OSCILLATOR REPLACEMENT FOR THE COLLINS R390A: This circuit, when used in conjunction with a divider and phase detector which are not shown, will replace the first and second crystal oscillators in the R390A. The varicap diode is a nonlinear device, so oscillation amplitude should be kept as low as possible. The oscillator is a common-base circuit providing maximum output impedance, and the 300-pF coupling capacitor feeds a clean waveshape to the emitter. A 1k trimpot is used to set the desired amplitude.—Eiichi Takarada, Rockford IL.





SIMPLE SWITCHABLE CW SELECTIVITY FOR THE KENWOOD TS-520S: Open the case of the transciever and remove all the knobs and dial face plate. Unsolder the five wires from the RIT control. Remove the RIT control. Mount a 0-5000-Ohm potentiometer with a push-pull switch in the hole where you removed the RIT control. Solder a six-inch length of hookup wire to each of the switch terminals on the new control. Connect the five wires to the new control (these are yellow, blue, orange, orange, and orange). Ground one of the switch wires to chassis. Connect the other switch wire to the relay's coil terminal. Connect the other relay terminal to the transverter output jack to obtain the 14 V dc for the relay. Disconnect the brown SSB i-f lead and attach it to the switching contact on the relay. Connect the normally-open relay to the CW terminal on the i-f board. Connect the normally-closed relay contact to the SSB terminal on the i-f board. Reassemble the rig. Calibrate the CW selectivity to a zero-beat obtained on WWV.—Harry A. Ober WB6CGZ, Canyon Country CA.



C1 220µF 15V
CR1 IN4444 OR EQUIVALENT
D1 SUBMINIATURE LED (RADIO SHACK 276-042)
R1 1M PC POTENTIOMETER
* VARY SIZE FOR OTHER TIME RANGES

SIMPLE MICROPHONE TIMER: To avoid accidentally timing out a repeater, install this 555-based timer circuit in your microphone. R1 can be either fixed or variable. A one-megohm resistor and a 100-uF capacitor provide a one-minute, forty-second cycle. The second circuit shown will provide a higher keyline output. The subminiature LED will be visible when mounted into a hole drilled into the microphone. To save space, the circuit can be built directly on the pins of the 555. The circuit will light the LED when the transmitter is keyed, and the LED will go out and the transmitter unkey when the timing cycle is completed.—John S. Wilcox KA4DZY, Millington TN.

NEW PRODUCTS

HAND-HELD COUNTER-TIMER

Global Specialties Corporation announces the new Model 5000 Counter-Timer. It is the first portable, hand-held instrument of its kind. The 5000 combines all of the important features and performance capabilities of a bench-top unit with the convenience of a fully portable, battery-operated instrument. The 5000 measures 7.6" × 3.75" × 1.7" and weighs in at 14 oz. (without batteries).

As for performance, the 5000 is designed to measure frequency, period, and pulse width with extreme accuracy and exceptional reliability. It features full signal conditioning including: attenuator (× 1, × 10, × 100), slope selection (+ or − edge for pulse-width measurement), ac or dc coupling, and variable trigger level.

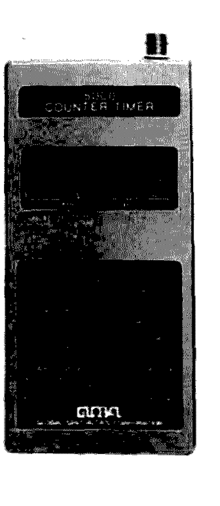
A high-contrast .43-inch LCD display offers 8-digit precision for fast and accurate readings. LCD annunciators indicate overflow, gate-open, and low-battery conditions. With a simple flick of a switch, the display-storage mode will maintain the last reading in the display indefinitely.

The 5000 features a unique automatic master reset logic. This time-saving reset function instantly clears the display and initiates a new measurement cycle eliminating erroneous partial measurement.

A self-diagnostic function performs analysis of internal logic and provides instant assurance of accurate operation.

The 5000 Counter-Timer has 3 modes of operation: frequency, period, and pulse width. Signal input is via BNC connector—input impedance is 1 megohm @ 25 pF for all modes. In the frequency mode, the 5000 can handle inputs from 0.1 Hz to 50 MHz. Gate times of .01, 0.1, 1.0, or 10 seconds can be selected. Frequency will be displayed in kilohertz on the easy-to-read LCD screen.

The 5000 will measure any periods from 25 ns to 10 seconds and deliver a single cycle measurement or an average of 10, 100, or 1000 cycles. Time will be displayed in μs. Pulse-width measurement from 25 ns to 10 seconds can be made. Either the high or low portion of the input signal can be selected.



The 5000 Counter-Timer from Global Specialties.

All of the controls on the 5000 Counter-Timer are convenient slide switches and are front panel mounted. These include: Trigger Level, Gate Time/Cycles Averaged, Mode, Power (On/Test/Off), Display (Normal/Hold), Polarity (+ to − or − to + edge selection in pulse-width mode), Coupling, and Attenuation.

The 5000 is powered by 6 AA nicad or alkaline batteries or an optional ac adapter/charger. Optional accessories for the 5000 include a 120-V-ac adapter/charger (MMAC-2), a 220-V-ac charger/adapter (MMAC-3), an automobile cigarette lighter adapter, a 24" BNC input cable terminated with color-coded quick hooks, an antenna, and a rugged carrying case.

For additional information, contact *Global Specialties Corporation, 70 Fulton Terrace, New Haven CT 06509-1942; (800)-243-6077.*

MOSCOW MUFFLER™ WOODPECKER NOISE BLANKER

AEA's Moscow Muffler™ Woodpecker noise blanker.

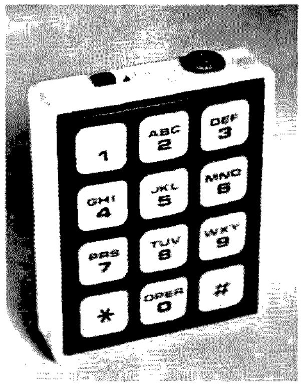
The AEA model WB-1 Moscow Muffler Woodpecker Blanker represents the latest of many AEA breakthroughs. This blanker is the first to offer effective blanking of the Russian Woodpecker signal with no modifications to the receiver required.

The WB-1 is designed to be connected in the antenna feedline between the antenna and the receiver. The WB-1 effectively blanks the interfering pulses before they have been stretched out by receiver tuned circuits, thereby causing the least amount of distortion possible.

Because the WB-1 is a synchronous blanker, it simply does not overload from strong adjacent channel signals. The overload condition is a significant problem with all i-f blankers, making the Moscow Muffler the most effective Woodpecker blanker under most band conditions.

In addition to the superior blanking features, the WB-1 offers an effective low-noise broadbanded 6-dB rf preamp with + 13-dBm intercept point. The preamplifier may be switched in or out whether or not the WB-1 is in the blanking mode.

The WB-1 Moscow Muffler Blanker is available in a transceiver version (model WB-1C) which features a carrier-operated relay (COR) for automatic transfer from receive to transmit. A COR ADJ control is provided for adjusting the relay dropout delay in switching from transmit to receive.



The Model 340 Thin-Coder™ from CES.

The WB-1 features a pulse blanking width control for reducing the blanking width to the minimum width necessary to achieve maximum blanking. The minimum blanking width will assure the minimum signal distortion that must result from placing holes in the received signal.

Blanking of both 10- and 16-Hz Woodpecker modes is achieved with the WB-1. At the time this brochure is being written, most Woodpecker transmissions are made with a 10-Hz pulse repetition rate.

The WB-1 is simple to operate and the most effective blanker of Russian Woodpecker signals that we have been able to test, including the most popular blankers built into modern transceivers. The WB-1 will typically display 45 to 50 dB of Woodpecker signal attenuation with no overload from strong adjacent channel signals.

The WB-1 comes with a 90-day limited warranty and is backed by the same AEA customer service that has earned AEA a prominent position in the amateur radio market. For more information, contact *Advanced Electronic Applications, Inc., PO Box C-2160, Lynnwood WA 98036; (206)-775-7373.* Reader Service number 476.

THIN-CODER™

The Thin-Coder, the smallest manual tone dialer made, is now being introduced by CES.

CES president Ron Hankins states, "The Model 340 Thin-Coder is truly a pocket-sized encoder. You don't need bulky cases or pouches to carry it with you."

The Model 340 measures 2-1/2" by 3-1/8" by only 3/4" deep and effectively dials the user into private networks, computer access, or dimension systems. Its rugged white case features a brown faceplate and white digit blocks. A convenient normal/high switch allows flexible volume control. Up to 10,000 long-distance calls are possible with the Thin-Coder's long-life 9-volt battery. CES encoders utilize single-contact tactile keyboards for extra reliability.

Communications Electronics Specialties is a leader in the design and manufacture of quality encoder, microphone, interconnect, and other specialized equipment for communications markets worldwide. For complete information on the Thin-Coder Model 340 Encoder and other CES products, contact *Ron Hankins, CES Inc., PO Box 507, Winter Park FL 32790; (305)-645-0474.* Reader Service number 484.

SIMPSON 470 CALCULATOR-STYLE DMM

Simpson Electric Company has introduced a brand-new calculator-style DMM, the 470 . . . a high performance DMM with features that are usually found only on more expensive units. 25 ranges are provided, including 1000 volts dc, 750 volts ac, and 10 Amps ac/dc. All voltage and resistance ranges are protected against transients up to 6 kV at 100 microseconds.

Convenient recessed human-engineered thumbwheel knobs control ranges and functions. An audible tone on the 2000-Ohm range provides fast checks for shorts and continuity. A diode test provides quick, good-bad checks of semiconductor junctions.

The easy-to-read, high-contrast, 3½-digit, 7-segment LCD display also features a low-battery indicator—battery life is about a year's average use.

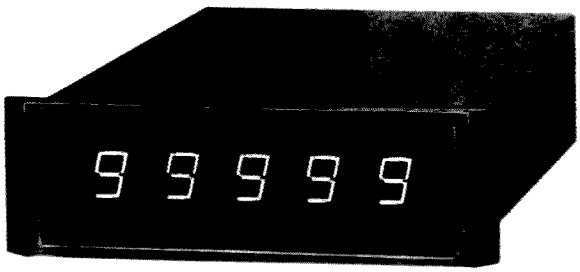
The instrument is manufactured by Simpson in the USA and carries Simpson's 1-year warranty. The high-impact, sealed case is 1.8" × 3.4" × 7.1". A two-way fold-out stand provides for convenient bench-top use or for hanging in an upright position. The 470 weighs less than 1 lb.

The 470 is supplied complete with UL-recognized, color-coded test leads with screw-on alligator clips, 9-V battery, and instruction manual. Optional accessories include Simpson's Amp-Clamp ac current adapter, as well as temperature, rf, and high-voltage probes, and the recently announced test-lead systems.

"The 470 and other calculator-style instruments will join the growing family of Simpson UL-listed DMMs," announced Simpson's sales director, Mel Buehring. "They will be available from leading electrical/electronics distributors worldwide."

For further information, contact *Simpson, Katy Industries, Inc., Electrical Equipment and Products Group, 853 Dundee Avenue, Elgin IL 60120; (312)-697-2260.* Reader Service number 483.

The Simpson 470 calculator-style DMM.



Non-Linear Systems' PF-5 frequency counter.

Microcraft's Videoscan-1000 high-resolution SSTV converter.

NEW FREQUENCY COUNTERS

Non-Linear Systems, Inc., recently announced two new digital-panel frequency counters capable of counting up to 10 MHz. Designated the PF-4 and PF-5 respectively, the new counters are packaged in miniature cases measuring only 15/16 × 2½ × 3½ inches and provide four selectable timebases: 0.01, 0.1, 1, and 10 seconds. The decimal point may be externally selected and the display may be blanked, dimmed, or tested externally.

The PF-4 is a four-digit display, while the PF-5 is a five-digit display. Internal signal-conditioning circuitry permits input signals having slow rise and fall times to be accommodated without difficulty, and both ac-coupled or dc-coupled inputs are accepted.

Input impedance is 75 kilohms and input signal amplitude may be +3 to +30 volts peak-to-peak. The instruments may be field-modified to accept up to 700 volts peak-to-peak. The units operate from an external 5-volt-dc supply.

For additional information, contact *Non-Linear Systems, Inc., PO Box N, Del Mar CA 92014.* Reader Service number 485.

SOLAR PHOTOVOLTAIC BATTERY CHARGER

The Phaeton II photovoltaic battery charger manufactured by International Solar Products Corporation of Durham, North Carolina, is being called "the most revolutionary development in rechargeable technology since the rechargeable battery." The unit produces 4.8 volts of direct-current power at 240 milliamps in peak sunlight. Four AA cells, two C cells, and two D cells can be charged with the unit. Batteries are fully recharged in 14 to 16 hours of sunshine.

Phaeton II measures 6" × 7" and weighs less than two pounds. It is constructed with spage-age materials—annodized gold or silver frame, heavy-duty aluminum battery cradles, and the same silicone covering used to protect the solar cells on orbiting communication satellites. The unit contains no plastic parts.

According to the manufacturer, the average consumer could spend as much as $100 per year on throwaway batteries to power the portable radios, tape recorders, toys, games, flashlights, cameras, and other electronic appliances found in many homes today.

For additional information, contact *International Solar Products Corporation, 1105 W. Chapel Hill St., Durham NC 27701; (919)-489-6224.* Reader Service number 478.

HIGH-RESOLUTION SSTV CONVERTER

Microcraft Corporation has announced the new Videoscan-1000, a high-resolution SSTV converter. Although the converter is compatible with amateur standard and first-generation SSTV equipment, the Videoscan-1000 also has two high-resolution modes producing 256-line pictures with 256 pixels per line.

The converter's pixels are quantized to 64 levels of gray, and it features a built-in gray-scale pattern to use in setting controls as well as three scan rates for optimum versatility.

With the Videoscan-1000's split-screen mode, four SSTV pictures may be viewed at one time, and the built-in memory can hold one frame of video from the camera or other sources. Your callsign may also be programmed into memory.

The converter takes care of all switching between the transmitter, microphone, and tape recorder. The only additional equipment necessary for operation is a camera and a monitor.

For additional information, contact *Microcraft Corporation, PO Box 513, Thiensville WI 53092; (414)-241-8144.* Reader Service number 481.

SELF-RESET POWER-LINE INTERRUPTER

Electronic Specialists expands its Ac Power-Line Interrupter series to include automatic reset models. Should ac line voltage be disrupted or exceed preset safety limits, the Power Interrupter disconnects ac power from controlled apparatus. A 4-minute time delay, followed by automatic self-reset, helps avoid wide voltage fluctuations associated with power-line malfunctions. An optional line voltage monitor is available.

Intended for installations operating unattended for long periods, the Self-reset Power Interrupter provides safety and protection for equipment and personnel.

Connecting to the ac line with a standard 3-prong plug, the Self-reset Power Interrupter can accommodate a 15-Amp resistive load or a 10-Amp inductive load.

For further information, contact *Electronic Specialists, Inc., 171 South Main Street, PO Box 389, Natick MA 01760; (617)-655-1532.* Reader Service number 477.

RTTY SOFTWARE

John Yurek K3PGP has introduced a line of TRS-80 programs for use in the ham shack.

CW runs on 4K Level I or Level II and turns the stock machine into a CW keyboard and receive terminal. The hardware interface for the program consists of a transformer and a transistor, both available from local Radio Shack stores. The program features a FIFO buffer and 8 regular buffers.

CW creates a split-screen display, allowing you to fill the buffer with a return message before you transmit. Speeds are adjustable from the keyboard, and text editing is provided for error correction.

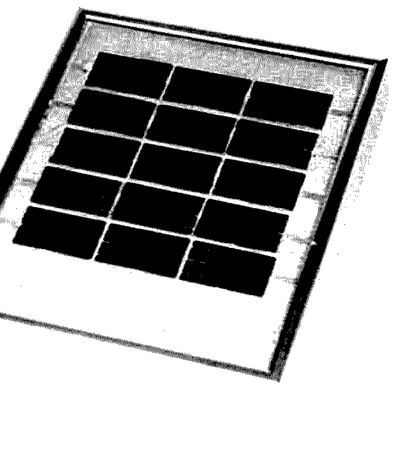
RY turns a TRS-80 stock machine into a 5-level (Baudot) teletype machine. This program also includes a FIFO buffer and a split-screen display. It will operate at all legal amateur speeds, and T/R switching is controlled automatically.

Both programs use the audio output of the cassette port to key the transmitter, without using the cassette relay.

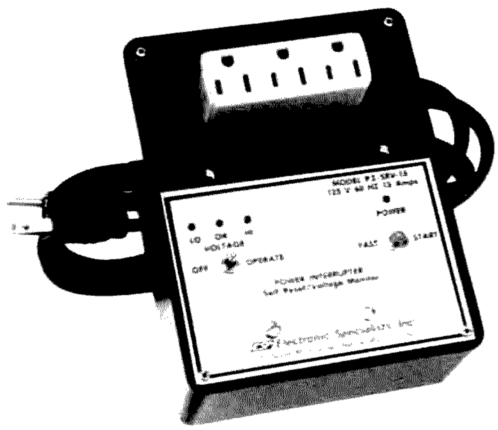
For $1, which is refundable with your first order, a catalog may be ordered from *John Yurek K3PGP, RD #6, Box 413, Irwin PA 15642.* Reader Service number 482.

WIDEBAND ANTENNA PREAMPLIFIER

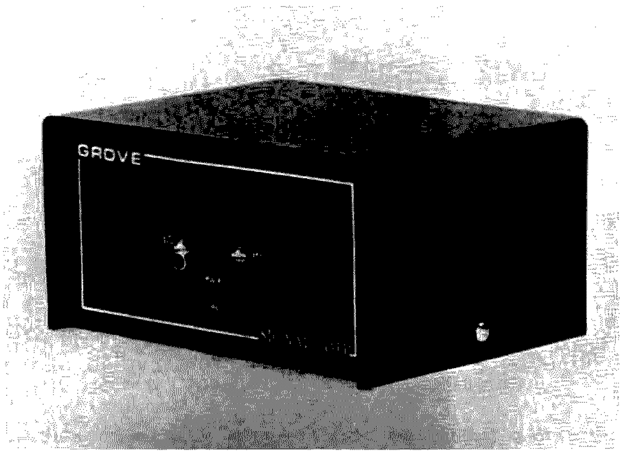
Grove Enterprises, prominent manufacturer of accessories for scanner and short-



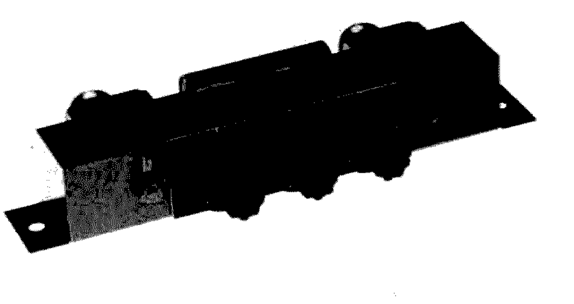
The Phaeton II photovoltaic battery charger manufactured by International Solar Products Corporation.



Self-reset Power Line Interrupter from Electronic Specialists, Inc.



The PRE-1 Signal Amp preamplifier from Grove Enterprises.



Microwave Filter Company's 3923-T TVRO filter.

wave reception, has just announced its PRE-1 Signal Amp masthead preamplifier.

Designed to provide high-gain, low-noise amplification for received VHF and UHF signals, the PRE-1 boasts a mid-band gain of at least 15 dB with a noise figure of only 1.8 dB.

The Signal Amp consists of a lightweight antenna-mounted preamplifier module and an indoor control unit. Switch-selectable high and low gain allows the user to customize his signal-enhancing needs.

Guaranteed to outperform competitive indoor preamplifiers, the PRE-1 Signal Amp comes with all necessary hardware, connectors, and instructions. For additional information, contact *Grove Enterprises, 140 Dog Branch Road, Brasstown NC 28902; (704)-837-2216.*

TUNABLE TVRO FILTER

Microwave Filter Company's new 3923-T bandpass filter tunes to any of the 24 TVRO transponders by means of three calibrated dials.

When tuned to a particular transponder, the 3-dB bandwidth is 40 MHz with less than 1.5 dB loss. Selectivity is 30 dB at ± 76 MHz. The new filter features type-N connectors and passes dc power. Delivery can be made in ten days from date of order, and the 3923-T filter comes with specification sheet and tuning instructions.

For more information contact *Emily Bostick, Microwave Filter Company, Inc., 6743 Kinne Street, East Syracuse NY 13057.* Reader Service number 479.

REVIEW

FACSIMILE WEATHER-CHART RECORDER BY ALDEN ELECTRONICS

Remember the old adage, "Everyone talks about the weather, but nobody does anything about it"? Well, that's not quite true—if it ever was—and Alden Electronics of Westborough, Massachusetts, is surely proof that somebody really does do something about the weather. They have introduced a facsimile weather-chart-recorder kit for the home hobbyist and ham.

Specifically, Alden Electronics is one of the world's largest manufacturers of radiofacsimile receiving and recording equipment. . .equipment that prints charts of significant weather information from around the globe, gathered by weather stations and rebroadcast in coded form for use by ships, aircraft, scientific expeditions, military and oceanographic groups, and many other stations.

The world depends upon radiofacsimile weather charts and satellite photographs for up-to-date information about storms, icebergs, significant changes in weather patterns, and other vital data needed by virtually everyone who lives, works, and travels in an interdependent world. Merchant mariners, naval officers, fishermen, and small boatmen make critical decisions based on local weather and ocean conditions. Air force officers, pilots, commercial airlines, airport operators, and others make critical decisions based on weather and atmospheric conditions. Modern radiofacsimile and satellite technology is now able to bring timely and accurate weather information to these users on a worldwide basis. Correct interpretation of the information inevitably leads to increased safety, improved efficiency, and even competitive advantage.

It has been said that a picture is worth a thousand words, and so it seems to be with weather information whose presentation in chart or picture form is so much more meaningful to the end user than information represented merely by strings of coded symbols, numbers, and letters. The location of major weather systems, storm fronts, areas of violent oceanic or atmospheric activity, and similar information can be seen and understood quickly on a weather map or from a satellite photograph. Therefore, if your own personal situation or livelihood depends on or is associated in any way with weather-related phenomena, you are certainly a candidate for Alden's goods and services.

The Alden weather-chart recorder prints weather charts and satellite pictures from radiofacsimile signals transmitted by a network of government-owned and -operated stations located around the globe.

The recorder requires an external receiver. It features solid-state circuitry and a simple electromechanical design to ensure long, trouble-free operation.

The Alden weather-chart recorder uses electrically-sensitive paper packaged in handy, disposable cassettes, the 11"-wide paper requires no threading. . .and replacement involves the mere insertion of another cassette. The printing process is quiet and free from smoke, odors, and fumes. No venting is required, and the compact size and light weight permit a variety of desktop or wall-mounting arrangements.

Background and Amateur Applications

Many hams have their own home weather stations which record or display temperature, pressure, and wind velocity. . . and weather is usually a part of the conversation between two hams. It's good fun to tell the other station just how bad (or how good) your weather is, compared with that in his own area. Historically, however, facsimile has been used for the transmission of other information—maps, schematic diagrams, drawings, photographs, and other images.

Radio amateurs have often built their own fax transmitting and receiving equipment, and many have converted surplus military or commercial units to this purpose.

There are several systems of encoding and decoding fax information for its broadcast and reception, all of which work satisfactorily. None need be discussed here, because the information is available in a variety of references on the subject.

Some hams have received the radiofacsimile weather information direct from the satellites that broadcast it, while others prefer to use the information rebroadcast on the HF bands by weatherfax stations.

In one sense, fax is like RTTY, amateur television, or similar modes of communication. . .it is enjoyed by small, select groups of hams who prefer the challenge and fun of doing something slightly different. For a long period of time, hams built their own TUs for RTTY reception and converted old Model 15s or Model 19s to amateur use. Then, with the revolution in solid-state electronics and computers, home-made apparatus gave way to commercially-available units of advanced design and infinitely increased capability.

It appears that radiofacsimile is now on that threshold of development at which commercially-available units have made home-built or converted surplus units a thing of the past.

WEATHER-CHART-RECORDER KIT MODEL 9321
SPECIFICATIONS

Recording rate: 120 spm (scans per minute).
Index of cooperation: IOC 576 CCIR, 169 lines per inch.
Control signals: Automatic start, stop, frame; manual start and frame.
Start: Signal shifting between 1500 Hz and 2300 Hz at a 300-Hz rate for 5 seconds.
Frame: A 1500-Hz signal interrupted by a short burst of 2300 Hz each scan line. Duration—20 to 30 seconds immediately following start signal.
Stop: Signal shifting between 1500 Hz and 2300 Hz at a 450-Hz rate for 5 seconds.
Circuitry: Solid state.
Input impedance: 600 Ohms balanced.
Input frequencies: FSK-1500 Hz black, 2300 Hz white.
Scanning electrode: Stylus belt.
Recording paper: Alfax electrosensitive paper in throw-away cassettes with built-in printing electrode. Each cassette contains 35 feet of 11-inch-wide paper.
Input voltage: 115 V ac ± 10%, 50/60 Hz.
Maximum power: Standby mode: 10 Watts; operating mode: 30 Watts.
Net weight: 10.1 pounds.
Dimensions: 3-5/8" H, 17-1/16" W, 10-1/2" D.

Alden's Weather-Chart Recorder

Our staff received two units for test. . . one ready-to-go, and the other a kit. Each was accompanied by an amply illustrated and detailed manual which told how to connect the unit to the receiver, and how to tune and adjust it for best reception and printing. The kit unit had, in addition, a construction manual which included pictorial as well as schematic diagrams, plus detailed step-by-step instructions for the mechanical and electrical assembly.

The Kit

The kit arrived packed in a large box divided into twelve or so internal compartments, each partitioned from its neighbor by corrugated paper barriers. Each compartment was numbered and contained a correspondingly-numbered plastic envelope of parts wrapped in protective packing material. The manual calls out the contents

of each compartment and invites the kit builder to identify, check off, and repack each component ready for use.

Everything you will need, including solder, is included. Most of the more difficult assemblies have been prefabricated and subassembled so that you won't have any trouble with difficult or critical components. You assemble the mechanical parts first, according to a logical step-by-step procedure. Then, you solder the precut wires to length and solder them to the subassemblies. Finally, you interconnect the wires, harnessing them as you go.

All critical construction, board-stuffing, testing, and adjusting has been done for you, meaning that your task will be pleasant, simple, and straightforward.

Two of us started construction on Friday evening, each helping the other with the work of selecting and positioning parts, fastening them in place, connecting them, and checking them off in the manual. The work goes fast, and there is nothing to be done that could not be handled by even a beginner.

Saturday evening saw all but final assembly and checkout. . . which took place on Sunday morning. We logged 24 man-hours (12 hours total time) on assembly and test.

Preliminary checkout and test before hookup to radio receiver is done with a multimeter and consists of measuring some resistances, voltages, and continuity. Again, each step of the way is detailed in such a way that the procedure is fail-safe. There is no such thing as a smoke test.

Operation

Alden thoughtfully included a worldwide marine radiofacsimile schedule in which you will find a list of stations around the world which broadcast the radiofacsimile signals. We tuned our all-band, general-coverage Icom R70 receiver to the Halifax, Nova Scotia, and Norfolk, Virginia, stations whose signals came roaring in on their assigned frequencies.

Also included is a *Facsimile Products Guide*, which is an aid for interpreting HF radiofacsimile charts transmitted from the US Naval Eastern Oceanography Center in Norfolk VA. The guide is reproduced with permission of the US Naval Eastern Oceanography Center, whose personnel originally prepared it. You will find information covering broadcast frequencies and schedules. Each chart is illustrated and described in detail, covering atmosphere analysis, atmosphere prognoses, oceanographic analysis, and oceanographic prognoses. The charts are typical of what is transmitted worldwide. Using this information, you can tune in to the exact information you want or need, and immediately start receiving pictures and charts.

There are only two connections for you to make with the finished weather-chart recorder. One is to plug it into the house mains—115 V ac. The next is to connect the terminals on the back of the recorder to the audio output of your receiver and to ground, respectively. Although the instructions called for 600-Ohm output, we were able to receive perfectly satisfactory charts using the 3.2-Ohm receiver output. Later, we built a little impedance step-up device that transformed the R70's output to approximately 500 Ohms for a better match to the unit, although this was not considered necessary.

After connection, and before turning the unit on, you make sure that the paper cassette is properly installed and the cover of the unit (which has a safety interlock) is snapped into place over the paper cassette.

As you tune in the USB audio-frequency-shift signals on your receiver, you will notice two little LEDs on the top of the recorder blinking red and green. The green LED represents the white image, and the red LED represents the black image on the paper. We found that the receiver's RIT (incremental tuning) control helped adjust to the exact frequencies needed after the main tuning dial was locked on to the frequency. Proper adjustment is thoroughly covered in the manual.

The next step is to depress the start switch, which begins the drum rotation and the stylus scanning. If the broadcast is already in progress, you will need to press the frame button to center the map on the paper. The weather-chart recorder is set to receive broadcasts at 120 lines (scans) per minute, which is the standard for most stations you will tune.

After a few minutes, you'll see the paper coming out of the recorder with a map or picture on it. Then, it's just a matter of waiting until the map or chart is complete before you tear the paper (or cut it) to separate the completed picture.

A very nice feature of the recorder is its auto-start and auto-stop function, which allows you to leave the unit in operational condition, but silent, until a broadcast of live material begins. The broadcast itself will issue start and framing pulses which will activate your recorder and properly frame the picture.

After a transmission, a stop pulse will be transmitted, stopping the machine and placing it in the standby mode, ready for another chart.

It was fun to see the satellite picture taken over the North Atlantic just a few hours before, showing the cloud cover (what else?) over the New England area. Much of the United States is covered, as well as most of the North Atlantic ocean. You can see the Caribbean islands, some of Central America, and parts of Greenland and Iceland.

The weather charts containing pressure isobars, temperature and wind-velocity data, and much more require some study to understand. You'll be fascinated at all the things you can discover with your recorder. For example, if you have a directional antenna, you can tune in the weather facsimile broadcast stations in England, France, Russia, Germany, the Pacific, Australia, Japan, etc., etc. These will give you charts and maps, as well as possible satellite pictures from their own parts of the world. You could even tell that DX station what his own weather is like, if you wanted to!

One of the better books available from Alden is *A Mariner's Guide to Radiofacsimile Weather Charts* which, in its 127 pages of text, charts, and photographs authored by Dr. Joseph Bishop, presents the best understanding of the earth's atmospheric and oceanic processes I have ever read. It is simple, lucid, and interesting. Even for someone who has no formal education in weather interpretation or analysis, the book is easily read and understood. By all means, be sure to order this book.

I must say that Alden has opened my eyes to an unexpected and pleasant facet of radio that I had never before experienced, in spite of my 32 years of hamming. Radiofacsimile reception is fun, it's fascinating, and—believe it or not—it kept me off the ham bands for two weeks while I explored the intricacies of the world's weather. . . through the weather-chart recorder.

You should avail yourself of the small (approximately 17" × 10" × 4") and lightweight (about 10 pounds) Alden weather-chart recorder ($995) and experience a new thrill in radio. It's guaranteed to be fun and educational.

For further information, contact *Alden Electronics, Washington Street, Westborough MA 01581*. Reader Service number 488.

Alden's weather-chart recorder.

THE ICOM R70

The Icom R70 is a general-coverage communications receiver covering a frequency range of 100 kHz to 30 MHz. Newly introduced to the market, it made me anxious to review it and share my impressions.

As with most hams, I could not resist the urge to unpack the radio and begin using it immediately without, of course, reading the instruction manual. It is because of this ease of use that I have such good things to say about it.

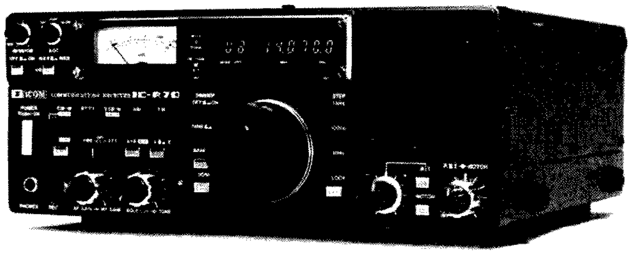
The IC-R70 has a front panel that is both uncluttered and functional. All controls are clearly marked, and after studying it for a few minutes I became aware of the radio's versatility. Bringing it to life was extremely easy, with just two connections, power cable and antenna. The 117/235-V-ac input is standard, with optional 13.8 V dc available. It is also internally modifiable to 100/200/220 V ac. The built-in speaker eliminated hunting around the shack for the phones or that bullet-riddled speaker that usually turns up.

The receiver is a quad conversion unit with its first i-f at 70.4515 MHz. The second i-f is at 9.0115 MHz. Without an antenna, I tuned across about all of its range, observing the birdies. The few I found at expected places were, however, far below the level of signals present with the antenna connected.

All of the initial testing took place on the ham bands using my triband beam. Twenty meters provided the kind of signals I was looking for, especially at the lower portion of the phone band. The R70 features a Pass-Band-Tuning (PBT) system allowing you to narrow the width of frequencies passing through the crystal filter. The passband can be moved up to 500 Hz from the upper or lower side in SSB mode (2.7 kHz in the AM mode). With the control in the OFF position, the passband is 2.3 kHz wide in SSB mode and 6 kHz in the AM mode. Using this control, I was able to hear stations that could not be received by using the notch control alone. No information was published as to the shift and depth of the notch filter, but it seems as effective as any other I've used.

While the PBT system took some getting used to, the frequency and mode selection did not. The radio has three selectable-tuning rates, 1 kHz, 100 Hz, and 10 Hz. These controls are located to the right of the tuning knob and, with a little practice, I could quickly zero in on the desired frequency. The one thing that did get a little confusing was the fact that the frequency does not roll over. Increasing from, say, 7.999.9 kHz returned you to 7.000.0 and not on to 8.000.0 kHz. This, however, turned out to be a time-saver when tuning from high to low ends of a band or vice versa. A LOCK push-button also is provided to disable the tuning knob, preventing accidental changes in frequency.

To the left of the tuning knob are three controls marked BAND UP, DOWN, and



Icom's R70 receiver.

HAM/GENERAL. These are used to increment or decrement the most significant digit of the frequency display when in the general-coverage mode. When in the ham coverage mode, these controls step you through 160m, 80m, 40m, etc., skipping all of the frequencies in between. It does stop at the new 10-, 18-, and 15-MHz bands, also.

Other front-panel controls include CW (wide and narrow—500 Hz), SSB, RTTY, AM, and FM (with the optional module). There is a separate FUNCTION push-button designed to select the sideband opposite the one you are in and select the narrow CW filter. The receiver automatically chooses upper or lower sideband depending on whether the frequency is above or below 9 MHz. A SQUELCH control also is provided, obviously getting used more for the FM mode than any other. It did work very well in SSB mode, however, but only on strong stations. Its action was dependent on the agc timing, and in the slow setting took quite a while to open (or close). I cannot see any real need for it except in the FM mode.

The frequency-display panel includes a 7-digit readout with 100-Hz resolution; it displays which mode and vfo is in use. There are two vfo's that can be loaded with the current frequency information and called independently of each other. An RIT control is provided to shift the received frequency ±800 Hz from the displayed frequency. No indication is given on the display except for a status LED showing that the control is in use. A useful feature is the fact that the RIT control is automatically disabled once the main tuning knob is moved. It can be re-enabled anytime by depressing the push-button. This assures you that you are receiving the displayed frequency.

A built-in preamplifier and attenuator is switch-selectable from the front panel. Claimed attenuation is 20 dB, with no mention of the amount of preamplification. Judging from the S-meter indication, it seems to be in the order of 6 dB. An agc selector permits a timing of fast or slow, or OFF. This I found more than adequate for all types of communications using the fixed rates. A switchable noise blanker proved very effective in both the available narrow or wide settings. It also seemed very effective with woodpecker-type noise. No decrease in signal levels was perceived with the noise blanker switched in.

The built-in speaker provided good-quality reproduction of all types of signals. In the AM mode, SW broadcast stations were very enjoyable to listen to without the high-pitched sound that one might expect from such a small speaker. In any event, an external speaker jack is provided should you wish to use it, as well as a recorder output jack. The latter outputs an audio level independent of the volume-control setting.

Although advertised as a general-coverage communications receiver, rear-panel connectors are provided to allow easy use of the unit with a transmitter or transceiver. The IC-R70 has a mute input allowing it to be quieted during transmit. Transmitted signals can be heard in the receiver, however, by using its monitor function. The volume of the monitored signal can be adjusted with the front-panel control.

The rear-panel accessory socket can also be used to control VHF and UHF converters. The switching arrangement is covered in sufficient detail in the manual. Also available on the accessory socket is an output from the receiver's detector stage. This output is at a fixed level regardless of the volume or gain settings. It is intended to be used to drive a RTTY terminal unit. Other rear-panel connectors include a scope output from the first i-f (70.4515 MHz). This would be useful for using a panoramic-type display.

Rear-panel antenna connectors are of both the PL-259 type and spring-clip type. The former is intended for approximately 180 meters and up, while the single-wire input is intended for the AM broadcast band below. The coaxial connector is designed for a 50-Ohm-impedance antenna system, and no specifications are given for the long-wire connector. No provisions are made for antenna matching, leaving it entirely up to the user to determine optimum performance.

My final comments deal with the instruction manual and schematics. As one who likes to maintain his own equipment, I found the documentation included totally lacking in content. The manual is an excellent operating instruction manual, but very little information is given on circuit description, troubleshooting, and general maintenance. The schematics are of the type showing detail of individual circuits, but interconnections are vague.

In summary, I would consider this receiver an excellent value. Its performance would make it suitable for the beginning ham, as a standby receiver for the shack, or to fill the void between hamming and casual listening. Its usefulness for Field Day or emergency communications cannot be overlooked. Also, I don't think the new or seasoned SWL could find fault with its performance—again making it a worthwhile addition to the shack. My wife, on the other hand, did not like the radio; that was after I told her that I would like to have one.

For further information, contact *Icom America, Inc., 2112 116th Ave. NE, Bellevue WA 98004; (206)-454-8155.*

CK-2 MEMORY KEYER

Keys and keyers, like tools, are interfaces between a worker and his work. The right tools make the job easier—even pleasant. Sometimes, when the work is pleasant and the craftsman is in a proper frame of mind and the tools are of superb quality, the tools become an extension of the craftsman—seeming to have no independent existence—and the finished product becomes a work of art.

In case you wonder what all this has to do with a product review, let's go back to the beginning and talk about keys and keyers.

Each CW operator prefers a certain type of key, and within that type exists an almost infinite variety of examples. Dozens of varieties of hand keys are in daily use, and the same holds true for semiautomatic mechanical keyers, electronic keyers, iambic keyers, and memory keyers. Each has its own group of devoted adherents—operators who swear by a particular kind or make and wouldn't have any other.

Memory keyers recently have come into greater use and acceptance than ever before, particularly by contest operators, for very good reasons. Electronic memory keyers not only have the capability of forming nearly perfect Morse characters into ideally spaced and "weighted" letters, words, and sentences, but they also have the ability to store words and sentences for later transmission, merely by pushing a button or touching a keypad. In typical contest work, the same message or exchange is sent over and over again, meaning that repeated retransmission of such a message from memory is both practical and necessary if high contest scores are to be obtained. Non-contesters also have found that a CQ message is practical, and even the simplest memory keyers now in use permit limited storage of simple messages.

In the field of electronic keyers, Morse trainers, CW-generating devices, and character-encoding and -decoding devices, Advanced Electronic Applications of Lynnwood, Washington, has carved a niche for itself and has gained a reputation for quality and reliability. AEA electronic memory keyers set the pace for others to follow with their Morsematic—a do-everything memory keyer and top-of-the-line product which, in the hands of experienced operators, is equally capable of sending exquisite CW or teaching new operators to do the same. Following on the heels of the Morsematic came the CK-1, a contest keyer with all of the features of the more expensive keyer (except for the "beacon" feature and training capability) at a significantly lower price.

The Morsematic and CK-1 offered selectable characteristics of "weight" (i.e., dot-dash length ratio) and spacing, speed control, and message storage, all available by means of a keypad located on the top of the unit within easy reach and sight of the operator. Beyond that, there were pitch and volume controls which allowed the operator to adjust the keyer sidetone to exactly suit his or her preference. Finally, AEA packaged all of these features into a neat, lightweight, and versatile box that conveniently fits on the disk or table at the operating position and unobtrusively gives the operator station command from tune-up to rapid-fire exchanges.

Now, the CK-2

Mike Lamb N7ML and the folks at AEA have just released their newest electronic memory keyer, the CK-2, which incorporates the CK-1 features and adds a few more to make CW even more pleasant and simple. CK-2 stands for Contest Keyer, second model, but it also has a name: Contester.

Recently, I was fortunate to be asked to review the Contester for *73*. Fortunate, because I am a CW afficionado and because I had heard so much about the CK-1 and Morsematic but had used the Morsematic only a few times and the CK-1 not at all.

Let's take a look, together, at the CK-2, pretending that we are seeing it for the first time.

The sturdy 10" × 10" × 4" cardboard carton is your first clue to the careful and rugged packaging. Inside, you find the CK-2 neatly sealed in a plastic bag and nestled down into its shock-protective wadding. Alongside, you'll see another plastic bag containing the following items: a battery-eliminator-type power supply (optional) that plugs into the wall and furnishes 12 volts dc at .35 Amps, a three-circuit, PL-68-type plug attached to a length of two-conductor shielded wire, a separate dc power plug and cable for attaching the CK-2 to a separate dc source, and a 2-circuit PL-68 plug connected by a shielded cable to an RCA-type phono plug.

AEA has thought of nearly everything, because the 3-circuit plug connects your keyer paddle to the CK-2 and the 2-circuit PL-68/RCA phono combination connects the CK-2 to your rig. Not much else to do.

Now for the *piece de resistance*, the CK-2 itself. The housing is a matte-black-finished metal box with rounded corners, measuring approximately 2" high by 5" deep by 7" wide. A twelve-button keypad occupies the right-hand top surface of the CK-2, and two knobs—a switch and an LED—occupy the left-hand top surface.

The first knob is the on-off/sidetone-volume control, and the second is the delay max/min control. The switch activates the memory-repeat function, and the LED is a full memory indicator. The rear panel contains the power jack, the paddle jack, and the key + and key − jacks which allow your CK-2 to key a high-current tube-type rig that uses cathode keying, or a low-current, solid-state keying circuit.

My particular keyer has serial number 364, and was inspected by "Robin"—a nice touch in this day of faceless manufacturers and nameless inspectors. You have the feeling that AEA cares about you and wants you to know who they are in case you need their help. Bravo! A confidence-builder that costs very little but means a lot.

We can't forget the instruction manual that accompanies the keyer. It's there, all right, and tells you how to operate the CK-2 in each of its various modes and parameters. Now let's plug the CK-2 in and turn it on to see how it plays.

Memory Functions

The CK-2 memory storage accommodates up to 500 characters in either a single group or in up to ten different groups, selectable by the keypad.

Two basic types of memory storage are available: real time or auto memory. Real-time memory means that everything you send, including pauses between characters and words, is loaded and counted in the 500-character group. Auto memory means that whenever you pause between characters or words, the CK-2 begins counting to itself, and when you have accumulated the equivalent of a word's worth of spaces, it shuts down—thereby saving you lots of space. For the speed demons this may not be necessary, but for us slow thinkers it's a real boon. Counting begins again when you send the next character.

By switching on the "memory load" function and then keying **9, you select the auto-load function. If real-time loading is your preference, a mere *9 will get you there.

Memory location is keypad-selectable, too. By selecting any digit between 0 and 9, you can put each message into that particular storage space ready for later recall.

The # symbol terminates memory loading. Already-loaded messages can be deleted from memory when desired merely by pressing #N, where N is the number of the memory location in storage. If you forget where you put it (as I have done), that's your problem. . . you'll just have to keep trying until yc find it.

In the playba ode, your message keeps going out over the air (at the selectable delay-between-messages of your choice) until you hear an answer. Just a single tap on your paddle will halt the message and allow you to pick up the break. If, or when, you wish to resume the message, all you have to do is request it from your friendly Contester.

Oh, yes, before I forget. You can edit messages as you load them without having to start all over again—a real time-saver!

The Contester's memory includes a long-term "keep-alive" circuit, battery-powered from an alternate power source. . . a 9-volt transistor battery, for example (not supplied). This feature allows you to keep intact those previously-stored messages while you travel to the contest site or to your Field Day location.

Take some time to get acquainted with your CK-2 before you try out the message-storage functions. There's a lot to learn, and it's best to relax with the regular functions before beginning any new ones. I might add that the automatic message-repeat function will be available to you when you need it, and the delay between repeats can be adjusted from about 2 sec-

onds to 3 minutes . . . affording you almost infinite variations between casual rag chewing and high-speed contesting.

Operating Your CK-2

When you turn on the CK-2, it beeps once at about 500 Hz, the sidetone baritone note. If you prefer tenor, you can get that, too. Here—let's try it: press *1 and hold the 1. Notice the tone climbing the scale, the pitch getting higher and higher? Okay, when you reach the note you like, just lift your finger off 1 and there you are. Simple, huh? (Lower the tone with **1.)

Now, how about speed? Well, there are two speeds already preset into the CK-2. Here—try keying something—at about 20 wpm, right? That's memory A for speed. Now, touch *9 and try keying. About 30 wpm. That's memory B. Let's say you want to change both memory A and memory B for speed—no problem. **8NN lets you put the desired speed in memory A; the NN is the speed in wpm that you want. Example: **815 will give you 15 wpm. Okay, let's set that in memory A. In memory B, let's put in 25 wpm. Hit **925 and there you are! Now, by hitting *8 you get 15, and *9 gives you 25. (If you turn off the keyer, and then come back on, memories A and B will have reverted to their original 20 and 30 wpm respectively.)

Here's another neat trick. Suppose you don't know the speed you want (in terms of a particular number of words per minute) but wish to listen until it sounds about right. Okay, simple: press *6 and hold the six while keying your paddle on the dot or dash side. When the length is what you want, remove the pressure from the 6. Let's say you want to decrease speed smoothly: press *7 and hold the 7 until the speed is down where you like it. Release the 7, and presto, right on! Speeds from 1 to 99 wpm are available, in 1-wpm increments.

Here's another f'rinstance: Suppose you want to keep a serial-number record of the messages sent out by your CK-2. No problem; just press *0 and set the message number into memory. Incrementing from that number forward will then take place automatically each time the message plays back from memory. If you want to reset to 01, press **0. To set the serial number to any desired value between 0 and 9,999, you just press *0NNNN (where the Ns represent the number).

Other Features

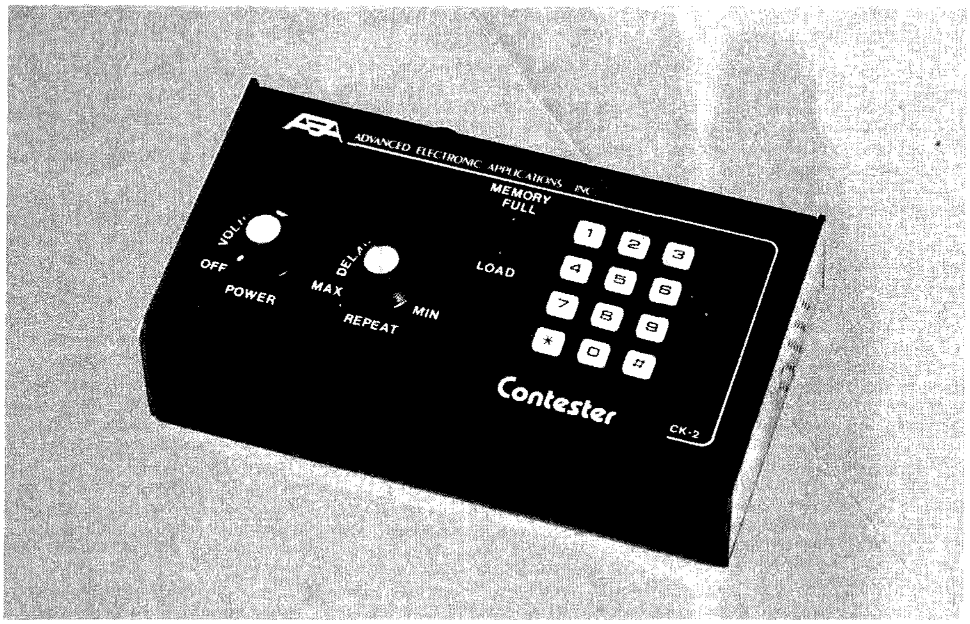
The CK-2 allows you to tailor its parameters to your own liking. For example, if you prefer fully-automatic dot-and-dash completion for iambic keying, you can have it. If you prefer a bug version, you can have just automatically-completing dots and manual-dash formation. If you don't like iambic keying but just want to have an ordinary electronic keyer, that's possible, too.

For tuning the rig, you can select a tune mode which will key the carrier until you have completed your adjustments; a tap on your paddle will instantly shut it off.

The CK-2 has rf protection against false keying, too. This might have been somewhat of a problem with solid-state devices operated in strong rf environments, but AEA has solved the problem for you.

Your friends at AEA provide full-service backup for your purchase and are always willing to help with questions or problems should they arise; since they are your friends, they want satisfied, enthusiastic customers.

You'll find the instruction manual complete, not only for using the CK-2 but also for troubleshooting and repairing it should that need ever arise. Schematic and pictorial diagrams plus a parts list are provided in the manual.



The Advanced Electronic Applications CK-2 memory keyer.

Summary

These are by no means all of the tricks that the CK-2 can teach you, but you'll learn them all if you get one for yourself. I'm still learning some of them myself!

What *didn't* I like about the CK-2? Well, very little, to be honest. It did tend to show me where my shortcomings lie, and it forced me to get out of my comfortable rut and learn something new and different. As Churchill was supposed to have said: "I love to learn, but I hate to be taught." In my case, the CK-2 was a good teacher—and I didn't hate it at all. In fact, learning was pleasant, fast, and fun.

If you need a lifetime keyer that allows you to grow in proficiency while matching your requirements exactly—the CK-2 will stick with you all the way. On the other hand, if you're just a Sunday afternoon rag chewer, the Contester can be a trusted and patient friend. The choice is yours . . . and the CK-2 can do it all.

The CK-2 is priced at $139.95 and a dc adapter is available for $14.95. For further information, contact *Advanced Electronic Applications, PO Box C-2160, Lynnwood WA 98036; (206)-775-7373.* Reader Service number 486.

THE PALOMAR ENGINEERS PT-407 ANTENNA TUNER

The true test of a race car is on the long track in Indianapolis, and the strength of a dune buggy is discovered in the heat of the Baja desert.

So, to test the Palomar Engineers PT-407 antenna tuner, I put it on the first floor of a brick apartment building, with a random-wire antenna and no earth ground.

And it performed flawlessly.

In an apartment, all of the possible problems of operating a station become a reality. Antenna space is extremely limited, TVI problems are multiplied by the closeness of neighbors, and the lack of an earth ground exacerbates the other problems. With these difficulties in mind, the PT-407 was hooked up between a Kenwood TS-520 and about 75 feet of wire.

My first surprise came during the tune-up. After having had visions of going through two sets of finals before I finally found an acceptable swr, I was pleased to settle in at 1.4 to 1 on 15 meters with two or three bursts of knob-fiddling. Tune-up on the other bands was just as easy, and I found that I could always get a match of 1.5 to 1 at the highest. However, on most of the frequencies tried, a lower swr could be found in just a few seconds.

Tune-up procedure for the T-network of the PT-407 is standard. Two controls—Antenna and Transmitter—adjust variable capacitors, and the 12-position Inductance switch selects connections on an air-wound coil. In addition, the tuner has a balun for open-wire feeds and a coaxial switch to use in conjunction with a dummy load or an antenna that needs no matching device. Its total capacity is for four antennas.

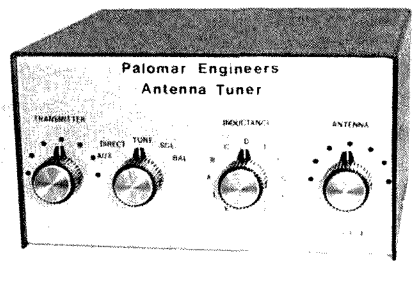
Tune-up is done at low power to avoid damaging the finals while they are loading onto a mismatch. The first control to be adjusted is the inductance; you set that at the lowest swr. The antenna and transmitter capacitances are interactive, making the second part of the tune-up the most trying.

The tuner will handle up to 300 Watts, which is enough to use with almost any rig running barefoot, and it takes up only 8″ by 8″ by 4½″. Construction inside the unit is solid; knowing from sad experience that a single poor connection is anathema to good output, I checked the unit over carefully during the first trial and could find no flaws.

With the case on, the tuner is unobtrusive yet handsome. The three-sided top is finished in a black crinkle, with a brushed aluminum front and back. The connections in back are made via three SO-239s and three porcelain insulators for a balanced feedline and the single-wire antenna.

To my surprise, the tuner proved to be quite broadbanded. Going from phone to CW on 40 meters required little peaking, and readjustment within band segments was not needed.

Assured that my finals were safe from the dangers of high swr, my attention turned next to the tuner's TVI-reduction capabilities. For this admittedly unscientific test, I used an old-model television with absolutely no shielding; my fellow apartment dwellers also (unwittingly) participated in this test. In my situation, TVI suppression is not good enough; the num-



The Palomar Engineers PT-407.

ber and density of television sets in my area necessitates a completely clean signal.

With the television on and next to the transceiver, there was minimum TVI. At voice peaks, the familiar lines we all know and fear broke the picture, but otherwise no interference was present. In the living room, a bare 15 feet away, there was no interference. And so far, I have not received any complaints from irate neighbors.

As with any component in a system, one unit's performance is limited by the other parts of the system—so other configurations could produce better or worse results. But the final question when using a matching device is if the tuner is absorbing most of the output to create an acceptable load. A few short minutes later, my question was answered in a QSO with KA7BEX in Louisiana and a second with KEØS in Colorado, both of whom gave me a good signal report.

Admittedly, most hams would not consider this great DX. But from the depths of an apartment building in Boston, Colorado is just short of a miracle.

AMATEUR RADIO CALL DIRECTORY

Since 1920, there has been only one directory of amateur radio operators. The *Radio Amateur Callbook* has been the sole source of names and addresses of hams worldwide—until recently.

Now, in addition to the *Callbook*, there is the *Amateur Radio Call Directory*, published by Buckmaster Publishing in Ridgefield, Connecticut. Though similar to the *Callbook*, the *ARCD* has a slightly different format and comes in three books, each indexed differently—by call, by name, and by area.

Like the *Callbook*, the *ARCD*'s callsign index ($12.95) is divided into three columns per page. However, where the *Callbook* has separate sub-columns for the state and the zip code, the *ARCD* only separates the state and zip by commas. This makes the *ARCD* more difficult to read or copy from.

In addition, the *ARCD* does not have some of the operating aids which are included with the *Callbook*, such as a prefix list, QSL bureaus, Q signals, and time charts. And although the *ARCD* is the same width and height as the *Callbook*, it is somewhat thicker. When using the *ARCD*, I found that I missed having that additional information at my fingertips.

The *ARCD*'s geographical and name indexes are about half the length of the callsign index, but they are priced substantially higher than the callsign index. However, both of these indexes are good ideas, and I am surprised that nobody published these books earlier.

The geographical index ($25) is divided first by state, and then by city in alphabetical order. The city is followed by the street address and the callsign, enabling the reader to cross-reference to the call directory and get the full name and address. Although this process is rather cumbersome, it does save space and reduce the amount of redundant information.

Each page is topped by the state abbreviation and the listing is divided into six columns per page. Fortunately, divisions between columns have been clearly marked.

This index will not find much daily use in the average shack, but it would be quite useful if a club were putting together a prospective member mailing list or estimating the density of hams in a given area.

The *ARCD* name index ($25) is an alphabetical listing, by last name, of all hams in the US. The index includes the full name, middle initial, callsign, and state, again enabling the user to cross-reference to the callsign directory for more information.

Nor will this index quickly become dog-eared, although I am sure enterprising hams will find uses for it. My first response was that hams more frequently know each other by first name than they do by last. However, this is a useful source of information for clubs or nets.

Together, these three volumes comprise an extensive source of information, and although their comparison with the *Callbook* is necessary and inevitable, the *Callbook* and the *ARCD* are useful for different purposes.

Because of the operating aids in the *Callbook*, as well as its format, I find it handier in the shack than the *ARCD*. However, when you need an index for uses other than filling out a QSL card, the various indexes of the *ARCD* prove to be a valuable adjunct to the *Callbook*. Together, the *Callbook* and the *ARCD* would provide a highly versatile source of information.

For further information, contact *Buckmaster Publishing, 70 Florida Hill Rd., Ridgefield CT 06877.* Reader Service number 487.

FUN!

John Edwards KI2U
78-56 86th Street
Glendale NY 11385

HOW HAMS VIEW THEMSELVES

Well, it's that time of year again. What time of year? Why it's time for the annual FUN! Poll, amateur radio's only free-form opinion survey where every ham gets his or her chance to speak out on the issues of the day. A ham tradition for three years.

If the past is any indication, this year's poll should manage to stir up a substantial amount of heat. And considering February's reputation for bitter cold breezes, a little heat just may be what we could all use right now. I can hardly wait until I see my mailman struggle up the icy walk to my house with a bag loaded with reader response forms. As you may have already guessed, there's a definite sadistic streak in KI2U.

This year, as in previous FUN! Polls, we're keeping some old questions in order to keep track on developing trends in our hobby, and adding some new ones to keep up with the times. Sharpen those pencils.

ELEMENT 1—BACKGROUND

1) Sex:
- A) Male
- B) Female

2) Age:
- A) 15 or below
- B) 16-21
- C) 22-39
- D) 40-59
- E) 60 or above

3) License class:
- A) Novice
- B) Technician
- C) General
- D) Advanced
- E) Extra

4) Number of years licensed:
- A) 1 year or less
- B) 1-5 years
- C) 6-10 years
- D) 11-20 years
- E) 21 years and up

5) Do you have a new (post-March '78) call?
- A) Yes
- B) No

6) How many hours a week do you devote to amateur radio?
- A) 0-1 hour
- B) 2-5 hours
- C) 6-10 hours
- D) 11-20 hours
- E) 21 hours or more

7) Which HF band do you use most?
- A) 80-75 meters
- B) 40 meters
- C) 20 meters
- D) 15 and/or 10 meters
- E) Don't operate HF

8) Which VHF-UHF band do you use most?
- A) 6 meters
- B) 2 meters
- C) 220 MHz
- D) 420 MHz and/or up
- E) Don't operate VHF-UHF

9) Which mode do you use most?
- A) SSB
- B) CW
- C) FM
- D) RTTY
- E) Other

10) How much money have you spent on amateur radio within the past year? (Include QSL expenses, magazine subscriptions, club dues, and other incidental expenses.)
- A) 0-$250
- B) $251-$500
- C) $501-$1,000
- D) $1,001-$2,500
- E) $2,501 and up

ELEMENT 2—SOCIAL CHARACTERISTICS

11) Has amateur radio influenced your career choice?
- A) Greatly
- B) Somewhat
- C) Not at all

12) Do you answer QSLs that include a self-addressed, stamped envelope?
- A) Yes
- B) No

13) Politically, how would you define yourself?
- A) Conservative
- B) Middle-of-the-road
- C) Liberal

14) Do you think amateur radio will exist 20 years from now?
- A) Yes
- B) No

15) How old were you when you first became a ham?
- A) 15 or below
- B) 16-21
- C) 22-39
- D) 40-59
- E) 60 or above

16) Were you a CBer before you became a ham?
- A) Yes
- B) No

17) Do you own a home computer?
- A) Yes
- B) No

18) Do you think hams, compared with computer hobbyists, are:
- A) More technically inclined in their hobby
- B) Less technically inclined in their hobby
- C) Both are about equally skilled in their hobby

19) Do you think that home computing is siphoning people (including youngsters) away from amateur radio?
- A) Yes
- B) No

20) Did you ever use a "cheat book" (not counting the *ARRL License Manual*) to upgrade your license?
- A) Yes
- B) No

21) If someone offered you ten million dollars, tax free, on the condition you give up amateur radio forever, would you?
- A) Yes
- B) No

22) Do you belong to a local ham radio club?
- A) Yes
- B) No

23) Have you ever attended a ham flea market?
- A) Yes
- B) No

24) Do you think the new ARRL leadership is better than the previous administration?
- A) Yes
- B) No

ELEMENT 3—OPERATING HABITS

25) Should Novices have phone privileges?
- A) Yes
- B) No

26) Do you think US phone bands should be expanded at the expense of foreign-station-only bands?
- A) Yes
- B) No

27) Have you ever used a personal computer in connection with your amateur radio activities?
- A) Yes
- B) No

28) Is it time to completely deregulate amateur radio by having the FCC turn over all responsibility for ham operation to the amateur community?
- A) Yes
- B) No

29) Where do you think the future of ham radio lies?
- A) On the HF bands
- B) On the VHF-UHF bands

30) Should we get rid of, or reduce in size, the CW subbands?
- A) Yes
- B) No

31) Do you think religiously-oriented nets have a place in ham radio?
- A) Yes
- B) No

32) Do you think politically-oriented nets have a place in ham radio?

RESPONSE FORM

Instructions: Read each question and mark your response by circling the appropriate letter next to the number of the question.

Element 1:	7) A B C D E	12) A B	19) A B	*Element 3:*	31) A B	38) A B	45) A B C D E
1) A B	8) A B C D E	13) A B C	20) A B	25) A B	32) A B	39) A B C D E	46) A B C D E

Comments: ____

Please mail Response Form to: John Edwards KI2U, 78-56 86th Street, Glendale NY 11385.

A) Yes
B) No

33) If, while tuning across a band, you heard a net of gay hams in progress, would you:
A) Jam it
B) Ignore it
C) Complain to the FCC or some other organization
D) Listen
E) Join it

34) If, while tuning across a band, you heard a net called "The American Communist Radio Society" in progress, would you:
A) Jam it
B) Ignore it
C) Complain to the FCC or some other organization
D) Listen
E) Join it

35) If required, could you solidly copy CW at the speed at which you were licensed?
A) Yes
B) No

36) If required, could you pass the FCC theory test for your license class without consulting a "cheat book"?
A) Yes
B) No

37) Have you ever purposely operated in an amateur subband you weren't licensed to use?
A) Yes
B) No

38) Do you think the FCC affects amateur radio in a positive manner?
A) Yes
B) No

39) Do you ever speak to foreign, non-English-speaking hams in their own language?
A) Always
B) Sometimes
C) I attempt it
D) Rarely
E) Never

40) Do you feel yourself competent to replace the finals in a tube-type rig?
A) Yes
B) No

41) Do you feel yourself competent to replace the finals in a transistor-type rig?
A) Yes
B) No

42) Have you ever built an electronic project from a kit?
A) Yes
B) No

43) Have you ever home-brewed an electronic project from a book or magazine?
A) Yes
B) No

44) Have you ever designed your own electronic project?
A) Yes
B) No

45) What do you think of contesting?
A) Great
B) Good
C) Okay
D) Don't like it
E) Despise it

46) What do you think of DXing?
A) Great
B) Good
C) Okay
D) Don't like it
E) Despise it

47) What do you think of repeaters?
A) Great
B) Good
C) Okay
D) Don't like them
E) Despise them

48) What do you think of traffic handling?
A) Great
B) Good
C) Okay
D) Don't like it
E) Despise it

49) Do you plan to use Phase III OSCAR within a year of its launch?
A) Yes
B) No

50) Do you plan to use the new 10.1-MHz band within one year of its opening?
A) Yes
B) No

HAM HELP

I have a Swan 350 and would like to know if anyone has added an RIT to this transceiver. I'll be happy to pay for any copying or postage fees.

James Harriges WB9RSK
542 E. Van Beck Ave.
Milwaukee WI 53207

I would like to find the manual (or copy) for the Alda 105. I am willing to pay a reasonable price.

Larry K. Pittman WD9EME
18919 E Rd., 410N
Hops IN 47246

I need the manual, schematic, or any information on a rack-mounted modem marked as both Periphonics DSU-400 and as I/Onex Type Autotone model 302. I am also looking for work in electronics in upstate New York. I have a BSEE, FCC General-class license, and I am very good with computers, especially assembly language.

Michael Moroney WA2VXY
18 Seville Drive
Clifton Park NY 12065

Wanted: AA, AB, AC, and AD coils for a National HRO-60 receiver.

Fred P. Robbins Jr. W5LNE
Star Route Box 166
Bay City TX 77414

I am looking for the Hallicrafters Super Skyrider model SX-28A, the UHF model S-37, and the Panoramic Receiver, model S-35. I will pay all costs.

Peter Dal Corobbo
18650 S. Marshfield
Homewood IL 60430

I need the manuals (or copies of them) for the Yaesu FT-7B and the Azden PCS 2000.

Larry Fields, Engine Dept.
USNS Silas Bent T-AGS26
FPO San Francisco CA 96661

I need a manual for a Model 75 Aerovox resistance-capacitance bridge. Can you help?

A. D. Buckley WB1AQV
14 Knapp Drive
Prospect CT 06712

Wanted: manual for the Tektronix 564 mainframe. I would prefer to buy it, but I am willing to copy a manual and return it.

Hugh Watson
59 Orchard St.
Elmwood Park NJ 07407

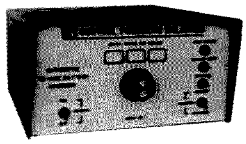
NICAD MEMORY ERASE — WHAT??

- Complete automatic operation
- Erases • Charges • Checks
- Rapid charges in 35 min. (typically)
- Automatically repairs shorted cells
- No dangerous heat build up
- Front panel selects up to 3 different packs
- Unlimited battery combinations with program modules (user programable)
- LED status indicators
- Supplied with universal EZ hook wire leads

Specify Voltage of Battery Pack(s) with order.

$79.95 plus $3.00 Shipping
(PA Residents add 6% sales tax)

Coming Soon — Multiple pack memory erase charger for municiple commercial applications - write for information or send requirements.



The GMS 401 is a complete automatic NICAD conditioner and rapid charger. Never before has this been offered anywhere at any price and it's so good it's being patented. NICAD memory characteristics must be dealt with otherwise your battery pack is not delivering all it could. The GMS 401 will automatically erase and rapid charge any type NICAD pack from 1 to 10 cells automatically.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 8

at that time, so this might be a good opportunity to mount a major DXpedition. The hams in Brunei are enthusiastic about this—anything to get DXers off their backs. I've talked with hams in Sabah about this, too, and perhaps the independence of Brunei might be a good excuse to mount an all-Borneo DXpedition. I'll bet we could get coverage on television for something like that. We might send a team to 9M8, 9M6, and YB7 as well as Brunei and put these countries on the air for a week solid. Anyone game for this? I think we could arrange for a very reasonable charter air flight, group accommodations at a reduced rate, and so on. I have been assured that licenses can be arranged if we start far enough ahead. I'd suggest this as a project for DX clubs, with each choosing one country for their group to activate. Then we could all get together in Singapore at the end for one hell of an Asian hamfest.

By the way, I've found that there is considerable enthusiasm from all of the DX amateurs in our starting a foreign operating news section for *73*. All of them are interested in keeping up with rule changes in other countries, reciprocal licensing news, DXpeditions, and anything else unusual happening around the world. This is a world hobby today, but none of the ham magazines has really treated it as such. We are all interested in knowing about countries which will be becoming independent, in the formation of new countries such as Qua Qua, in new certificates and contests, and so on. We want to know about major hamfests and conventions around the world. We'd like to know about any outstanding cases where amateur radio provided emergency communications.

With a couple new magazines in the works for 1983, I may have to skip the next Asian tour myself, but this is no reason for you to pass up this fantastic trip. Hit the major cities and their electronics shows, then ad lib some unusual spots on your way back home. You'll find the local hams outstanding in their hospitality. And, if you start well ahead of time, you may be able to get your own license and do some DXing from the rare end. By 1984, I think we'll be putting together the Borneo Super DXpedition if enough of you like the idea. As I told the chaps when we were going to Navassa, no matter what else you ever do in life, this is one experience you will never, never forget. The experience is priceless.

One little hint for those with the guts to make the decision to come to Sabah: You will enjoy it. I guarantee you will enjoy It. But be sure, if you stop at the Hyatt, not to take an inside room. The entertainment in the central atrium is loud and continues until midnight, filling the room with 90-dB sound. Take an outside room.

HAM HELP

I need schematics or service manuals for the Heath DX-150 transmitter and the Heath IO-10 oscilloscope. I will copy and return them.

William Bohnenberger
18 E. 199 St.
Bronx NY 10468

Wanted: a lower sideband crystal, 251.650 kHz, for the Collins KWS-1 transmitter. Please advise me of the condition and the delivered price.

Edward Dobbielaere
4184 Long Lake Road SE
Port Orchard WA 98366

Can anyone send me a copy of the schematics and manual for the Realistic DX-120 communications receiver? I will pay for copying.

John P. Centers
514 Pine St.
Wapakoneta OH 45895

Anyone who can provide historical information on the defunct American Legion net, which operated in California from 1924 to 1952, please contact me.

J. Phil Scherck WA7AGY
8987 Curbaril Ave.
Atascadero CA 93422

I am looking for the manual, schematic, or parts list for the Measurements Corporation model 62 VTVM. I will gladly pay copying and mailing costs.

Vernon Jones WB1BVH
32 Cat Mousam Rd.
Kennebunk ME 04043

I would like to get in touch with other users of the R390A/URR. I need a source for manuals, schematics, and modifications.

Bob Lombardi WB4EHS
2046B Renee Place
Melbourne FL 32935

I am looking for a manual for a Knight KG-685 color pattern generator and a tube chart for a B & K model 650 tube tester. I will pay for shipping both ways so I can photocopy.

Larry Schuldt
545 Willow Rd.
Marengo IL 60152

I am trying to find schematics for the Heath HO-10 monitor scope and the Ameco model CN 6-meter nuvistor converter. I will reimburse all expenses.

Howard Robb
340 S. 5th St.
Bird Island MN 55310

I would like to add 10-meter capability to my DenTron GLA-1000B linear amplifier. Please write me; I will defray costs.

George Gauggel
3660 Puuku Mauka Dr.
Honolulu HI 96818

I need a schematic and a manual for the Eico model 320 signal generator. I am willing to buy it or pay copying costs.

Edwin Adams KB3DH
RD4 Box 241A
Bloomsburg PA 17815

We need the manuals or schematics for a Fermont Engine Generator Plant 10-kW diesel generator, model J-141-1, bearing serial number J-141-0018. The generator is marked as a General Electric #LC7470B16 type 6J, model number 5SJ4254P22Y12. The battery recharging circuitry, marked Fermont #6064-0001, has been damaged. We will gladly make arrangements to obtain information on this generator.

Wayne Richardson
Lebanon Junction Area Coordinator
Bullitt County Division of Disaster and Emergency Services
Main St.
Lebanon Junction KY 40150

I am looking for information on the Western Electric Indicator BC 1152-A, particularly the schematic and data on the 3HP7 CRT. I will pay costs for copying and postage.

Torgny Karlsson SM7CFQ
Sandormsvagen 7
S-260 41 Nyhamnslage
Sweden

I am looking for pen pals in the US. I am 18 years old and an engineering student.

Isaac Maxwell Kyereboah
PO Box 078
Takoradi, Ghana
West Africa

I am looking for modifications for the Heath SB-101 transceiver. I am particularly interested in improving 10-meter reception, adding an RIT and improving the selectivity. I will answer all replies and refund expenses.

Paul Newman G4INP
3 Red House Lane
Leiston, Suffolk IP16 4JZ
United Kingdom

I need 3 tubes, type 12JB6, for my Drake TR-3. I cannot find these tubes in Brazil.

Walter Pereira Da Costa PY4ZO
PO Box 207
Araguari, Minas Geraid
38440 Brazil

I desperately need parts to repair my Hallicrafters FPM-300 transceiver. I will pay for a complete non-working unit or the audio amplifier module, a U401 balanced mixer assembly MX-1, part number 150-018555-001.

Robert Sondack VE2ASL
260 Rue Bellerive
St-Luc, Quebec
Canada J0J 2A0

I need the manual for the Hammarlund HQ-180A receiver. I will pay for copying costs and send a note of thanks.

Bob Napoli K2LGO
Box 158
Riverhead NY 11901

CORRECTIONS

In Fig. 1 of "The Automatic Beam Aimer," on page 23 of November's issue, the power-supply diode was drawn backwards. The cathode should be connected to the transformer secondary.

Avery Jenkins WB8JLG
***73* Staff**

The parts values were omitted from the "Headlight Reminder" which appeared in the November "Circuits" feature on page 109. Q can be any common PNP transistor, but a 2N3638 or a 2N2907 works well; D1 and D2 are 1N4002 diodes; R1 is a 5.6k, ¼- or ½-W resistor; R2 is a 4.7k, ¼- or ½-W resistor.

Avery L. Jenkins WB8JLG
***73* Staff**

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

There's a great old song written by James V. Monaco and Joe McCarthy called "You Made Me Love You." It's that kind of feeling that I get in February, what with Valentine's Day and all, along with the letters from you, the readers, whom I truly adore. Let's see what you all have to relate this month.

Starting with the "foreign desk" (sounds like "World News Tonight"), I have a note here from a colleague in Central America. David Reuben Harris, M.D., a physician in Costa Rica, is a TRS-80 user who is trying to obtain software for his Model I that will enable him to both copy RTTY and fully interface his computer on the air. Now, I have always been a fan of software solutions to "hard" problems, but not this time. A perusal through the published literature really fails to demonstrate much in the "strictly software" vein.

On the other hand, I have received a packet of material that just might answer some of Dr. Harris's needs. Kantronics, located in Lawrence, Kansas, produces a versatile RTTY interface, which we touched upon in December. With some more information in hand, let's see what they say it can do.

Their box, called "The Interface," is the hardware link that turns a computer and amateur transceiver into a highly sophisticated RTTY system. It allows transmission on Murray, ACSII, or Morse with essentially the same operating convenience.

The unit itself is contained in a small box that attaches to external devices through a series of jacks on the back panel. Inputs and outputs are provided which accept audio and digital inputs between speaker audio, computer, and accessory keyboard or key. Front-panel indicators include a tuning LED and bar-graph LED, used to center incoming signals within the demodulator's passband. There is even a loop driver available to switch an external 60-mA loop so that an antique Model 15 can be used as a printer for such a modern system.

No hardware of this complexity is any good without equally able software and, recognizing this, Kantronics has made available a group of programs known generically as "Hamsoft" that interface The Interface to the Apple II, Vic-20, TRS-80C, and Atari 400/800 computers. Additionally, it is entirely possible to write custom software to use The Interface with other computers.

An interesting possibility is raised by the note that the Hamsoft programs, which allow for Morse code in the 5-99-wpm range, 60-, 67-, 75-, and 100-wpm Murray, 110- and 300-baud ASCII, split-screen display, transmit buffer, Morse ID during RTTY, printer output, and more, will operate with other terminal units. That means that you might, and I emphasize *might*, be able to use the Hamsoft program between your computer and terminal unit if all else is compatible. Kantronics makes no promises that you can, but it might be interesting to try.

A further indication of the care that went into this product is a full section in the manual of The Interface which details modifications needed to operate with certain transceivers which present problems. Whether the modifications need be made to The Interface or the transceiver, it is spelled out in enough detail that accomplishing the change should be no real problem.

Kantronics has put together a nice package here, and I will be interested to hear from those of you who have used The Interface and Hamsoft in its various configurations. I am sure that Phil Anderson W0XI, president of Kantronics, and the other folks out there will be happy to answer your questions. Write them at 1202 E 23rd Street, Lawrence KS 66044, and be sure to mention 73's RTTY Loop.

Speaking of Phil Anderson, he passes along a question which several others have also posed. Kirk Baxter WB0AXX, in Mission, Kansas, and John Ryan, in Alcove, Quebec, both also are interested in several of the encoded RTTY signals heard on commercial frequencies. Kirk relates a series of such codes, including bit inversion, bit transposition, TOR codes, SITOR codes, ARQ, FEC, and SEL-FEC codes. These signals are uncopyable on a standard system and can represent a real challenge to the hard-core RTTYer.

The first few codes asked about are simple techniques, designed merely to ensure some degree of privacy. It is fairly easy to envision manipulating a standard Murray character to, say, invert one or more bits from mark to space, or vice versa. Thus, the letter "R" would change from 01010 to 00110, if bits two and three were inverted, and would print as an "I" on an unmodified machine. Similarly, one can consistently transpose two or more bits in each character, again rendering it unprintable without the key for deciphering.

These codes are not difficult to decode with a computer program which recognizes the cipher and undoes what the sender did. Of course, if the encoding station is really nasty, the characters can have bits both inverted and transposed, but that is another convolution.

The Murray code, as we all know, is a five-level code. While ASCII is the most common code using more than five bits, it is apparently quite rare on radio circuits. A complex series of codes is used on many commercial circuits which has error-detection abilities. Known as the Moore code, or CCITT No. 3, it is a seven-bit code sent synchronously, as opposed to the asynchronous Murray code.

Thirty-five characters are each composed of three marks and four spaces, in various combinations. If a character is received which does not have the correct number of marks and spaces, the receiving station can send a code to repeat the last transmission. This is called the "Automatic Repetition on Request" and yields the mnemonic "ARQ" when referring to this code.

Another code system which allows for error correction is the "Telex Over Radio," or TOR system. Some trademarks for systems using TOR include SITOR and SPECTOR. The TOR codes resemble the Moore system in their formulation, but are each four marks and three spaces; thus, the characters themselves are completely different. The FEC noted above is a Forward Error Correction in which each character is sent multiple times to receivers unable to request a correction. The receiver is set up to select any of the repetitions which meet the correct mark/space ratio and discard the rest.

Although this is an overview, I hope this explains the more unusual codes heard on the air. If there is sufficient interest, we may be able to devote more time in the future to schemes to decode some of these code types. Let me know with your cards and letters; I look forward to them.

I will close this month with a request from another reader out west. Bob Sanett W6TWR, in Van Nuys, California, is trying to hook up a Siemens T-1000 RTTY unit. He describes this as a daisy-wheel printer for TTY! Sounds interesting, but he needs any information he can get. Anyone with anything of note should drop me a line and send Bob a copy at PO Box 7323, Van Nuys CA 91409. I'm sure he will appreciate it.

Will try to outline some more on the terminal next month, and of course something from you, the readers. This is our column, yours and mine, and between old Model 15s and new computers, that's quite a range, here, in RTTY Loop.

MULTI-BAND SLOPERS
160, 80, and 40 meters
Outstanding DX performance of slopers is well known. Now you can enjoy 2 or 3 band BIG-SIGNAL reports! Automatic bandswitching • Very low SWR • Coax feed • 2kw power • Compact • Ground or tower feed • Hang from any support 25 ft. high or higher • Easy to install • Very low profile • Complete instructions • Immediate shipment • Check ok

3 BAND SLOPER · 160, 80, & 40 Meters · 60 ft. long	$ 43.00	trt.ppd
2 BAND SLOPER · 80 & 40 Meters · 41 ft. long	$ 30.00	trt.ppd.
3-BAND NO TRAP DIPOLE, 180, 80, & 40M · 113 ft. long	$ 86.00	trt.ppd.
2-BAND NO TRAP DIPOLE, 80, & 40M · 84 ft. long	$ 49.00	trt.ppd.

COMPARE the HAZER™
with foldover + telescoping towers

• Antenna systems mount on Hazer-Hazer follows parallel to outside of tower - Raise to tower top or lower completely to ground level.
• Safety lock system on Hazer operates while raising-lowering & in normal position. Never can fall.
• Weight transferred directly to tower. Winch cable used only for raising & lowering.
• Will support most antenna arrays up to 20 sq. ft.
• High quality materials & workmanship
• Safety - speed - convenience - smooth travel
• Ease to install and use
• For Rohn 20 & 25 tower — Other towers on request
Complete with winch, 100 ft. of cable, hardware and instructions.
HAZER II Heavy alum. $279.95 • $17.00 UPS
HAZER III Standard alum. $199.95 • $13.00 UPS
HAZER IV Heavy gal. steel $249.95 • $28.00 UPS
Specify mast diameter when ordering.

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

ARIZONA QSO PARTY

Starts: 1800 GMT February 5
Ends: 0600 GMT February 6

Sponsored by the Southern Arizona DX Association. Single-operator and club entries, all bands and modes but no repeater contacts allowed. Each station may be worked only once per band.

EXCHANGE:

RS(T) and state, province, DXCC country, or Arizona county. Novices and Technicians also sign /N or /T, respectively.

FREQUENCIES:

Phone—3895, 7230, 14280, 21365, and 28560.
CW—60 kHz up from lower band edge.
Novice—25 kHz up from lower band edge.

SCORING:

Count 1 point per phone QSO, 2 points for each CW or other mode QSO, and 4 points per QSO with Novice or Technician in the Novice bands. Arizona stations multiply QSO points by number of states, provinces, and DXCC countries. Others multiply QSO points by number of Arizona counties (13 maximum). The club station, W7NQ, also counts as 1 multiplier for non-Arizona stations. Anyone working all Arizona counties and W7NQ may double the multiplier.

AWARDS:

Certificates for the highest-scoring station in Arizona, non-Arizona, and Novice/Technician. In addition, certificates for highest score in any Arizona county, state, province, or DXCC country in which there are at least five entries.

Other certificates for Arizona and non-Arizona clubs whose members' scores combine for the highest score. Club entry must consist of at least five individual entries to be eligible. Club residency determined by mailing address.

ENTRIES:

Individual entries should show each station worked, exchange, and time and frequency of each QSO. Include a summary sheet of your scoring and dupe sheets for bands with more than 50 QSOs. Entry may designate one club with which you are participating. Deadline for individual entries is March 5th.

Club entries should be submitted by a club officer with a summary of callsigns and claimed scores. To be counted toward the club total, the individual entries must also designate the club. Deadline for club summaries is April 5th.

Include a large SASE for results. Entries should be addressed to: Southern Arizona DX Association, c/o Philip M. Stickney N7BUP, 1890 West Paseo Cuenca, Tucson AZ 85704.

SOUTH CAROLINA QSO PARTY

Starts: 1800 GMT February 5
Ends: 2359 GMT February 6

The QSO party is again sponsored by the Colleton County Contestors. The same station may be worked on each band and mode, simplex only. South Carolina mobile stations that change counties are considered new stations. Novice and Technician stations please sign /N or /T.

EXCHANGE:

RS(T) and state, province, country, or South Carolina county.

SCORING:

Phone contacts are worth 2 QSO points, CW contacts are worth 3 points. The multiplier for South Carolina stations is the number of states, provinces, and DX countries worked. Others multiply QSO points by the number of South Carolina counties worked (46 maximum).

FREQUENCIES:

Phone—3895, 7230, 14280, 21365, and 28560.
CW—3560, 7060, 14060, 21060, and 28060.
Novice—3725, 7125, 21125, and 28125.

AWARDS:

Certificate to top-scoring station in each South Carolina county, state, province, and DX country. Novices and Technicians compete only with other Novices and Technicians.

ENTRIES:

Include a summary sheet with your entry showing scoring and other information. Indicate each new multiplier in your log as it is worked. Novices and Technicians indicate class on your entry. Include a large SASE for results. Mailing deadline is March 5th. Send to: Colleton County Contestors, c/o Elliott Farrell, Jr. KE4VP, Rt. 3 Box 658, Walterboro SC 29488.

NEW HAMPSHIRE QSO PARTY

1900 GMT February 5 to
0700 GMT February 6
1400 GMT February 6 to
0200 GMT February 7

Sponsored by the Concord Brasspounders, Inc. (W1OC), to promote the Worked New Hampshire Award. Stations may be worked once per band, per mode. New Hampshire stations may work each other.

EXCHANGE:

Send RS(T) and country, ARRL section, or New Hampshire county as appropriate.

FREQUENCIES:

Phone—1820, 3935, 3975, 7235, 14280, 21380, and 38575.
CW—1810, 3555, 7055, 14055, 21055, and 28130.
Novice—3730, 7130, 21130, and 28130.
VHF—50.155 and 145.015 FM simplex, no repeaters.

SCORING:

New Hampshire stations score 1 point per QSO multiplied by the number of ARRL sections plus countries plus New Hampshire counties. Others score 5 points per New Hampshire QSO times the number of New Hampshire counties worked.

ENTRIES:

Send your entry no later than March 12th to the Concord Brasspounders, Inc., c/o Norman W. Littlefield, RFD 1 Buck St., Box 323, Suncook NH 03275. Include a large SASE for results and/or award.

VERMONT QSO PARTY

2100 GMT February 5 to
0700 GMT February 6
1100 GMT to 2400 GMT
February 6

Sponsored by the Vermont Amateur Radio Club (W1BD). Each station may be contacted once on each band and mode. Repeater contacts and multiple contacts with the same station on the same band and mode are invalid.

EXCHANGE:

QSO number and state, province, country, or Vermont county.

FREQUENCIES:

Phone—3930, 3960, 7230, 7260, 14280, 14320, 21360, 28570, 50.110, and 144.2.
CW—3530, 3730, 7030, 7130, 14080, 21060, 21160, 28070, and 144.1.

SCORING:

Vermont stations score one point per contact with any station. Multiply QSO points by number of states plus Canadian provinces plus countries (exclude US/Canada). Others score one point per Vermont contact and multiply by the number of Vermont counties (14 maximum).

AWARDS:

For non-Vermont stations, certificate to highest-scoring station in each state, province, and country and to highest-scoring Novice/Technician. Certificates will be given each Vermont station submitting a log. W/VT Award given to stations working 13 of Vermont's 14 counties.

ENTRIES:

Send SASE for official log and score sheets. Send logs/facsimiles, name, class of license, and address not later than March 1st to: D. Nevin KK1U, W. Hill, Northfield VT 05663. Include an SASE for a copy of the results.

QCWA QSO PARTY—CW

Starts: 0001 GMT February 12
Ends: 2000 GMT February 13

This is the 26th annual QCWA QSO Party, with separate weekends for CW and phone. You can work the same station more than once providing it is on another band. Only the bands listed under frequencies will count in this QSO party.

EXCHANGE:

QSO number, operator's first name, QCWA chapter identification (official number or name), and state or country. Members not affiliated with a chapter should use "AL."

FREQUENCIES:

Any authorized amateur frequency in the bands that are listed below is permissable. The following suggested frequencies have been selected to minimize interference to others, but please feel free to wander up or down from these if you so desire. Bands: 3530-3560, 7030-7060, 14030-14060, 21040-21070, and 28040-29070. The above are selected as a starting place. When pileups occur, don't be afraid to go to either side of these frequencies.

SCORING:

Each contact made with another QCWA

PARKING TICKET

AE5C/R 147.78/.18

PLANO AMATEUR RADIO KLUB

NEWSLETTER OF THE MONTH

Although most people do not like to get parking tickets, the hams in Plano, Texas, get one every month—and they enjoy it.

The Parking Ticket is the newsletter of the Plano Amateur Radio Klub, and it encompasses a rare combination of humor, information, and good looks.

The good looks came from recent experimentation with the newsletter, varying the type and layout in response to reader feedback. The result is a very clean newsletter; the columns are well laid out and rarely can a typographical error be found.

Inside features include a two-month calendar of events—not just a list, but a full-fledged calendar with enough room to write notes. Regular features include "Traffic Talk," an educational column on traffic handling, and "The Novice Corner," a tongue-in-cheek tribute to beginning hams. December's issue featured a review of some books titled *The EMP That Ate Worldwide Communications*, and *Practical Tree Pruning With Mobile Antennae.*

However, editor Rick Goodin N5CBI admits that he does have his limitations. "I had grand delusions," he said in a recent editorial, "of writing a coherent, cogent, and otherwise brilliant column, but that was quite a few hours ago when my body still felt awake and my cerebrum had not yet lapsed into autopilot."

Take a nap, Rick; you deserve it for a job well done.

73 encourages clubs to send in their club newsletters. Just address them to *73*, Pine Street, Peterborough NH 03458. Let us know what is going on in your area.

member will count as a single point. This year's contest has three multipliers: chapters, states, and countries. For each band, every new chapter is a multiplier of one, every new state (USA) is a multiplier of one, and every new country (ARRL DXCC list) is a multiplier of two. At the end of the party add up your total contacts for all bands and multiply it by the sum of all your multipliers for all bands. This will give you your total and final score.

ENTRIES:

Please keep separate logs for each band. Logs should include the following information: time (GMT), call, QSO numbers, name, chapter number or name, state or country. It is the responsibility of each contestant to provide a legible log (no carbon copies) and to list all claimed contacts. The total contacts and multipliers for each page should be recorded at the bottom of each page. The total contacts for the party should be recorded on the first page of the log. Log sheets will not be returned. Make sure you have correct postage when you mail your logs. Send logs no later than March 31st to: Spaceport Center #66, Donald McClenon N4IN, 3075 Florida Avenue, Melbourne FL 32901. Separate logs and scores must be submitted for the CW and phone parties.

AMERICA RADIO CLUB INTERNATIONAL DX CONTEST

Starts: 0400 GMT February 15
Ends: 2400 GMT February 16

Any amateur station making two contacts with America Radio Club DX member operators during the two-day contest will be eligible to apply for the Special Silver QSL Award. Stations making three contacts will be eligible for the Special Gold Silver QSL Award. Contacts must be during the two-day period listed above. Suggested frequencies include all authorized frequencies in the 10-, 15-, 20-, and 40-meter phone and CW bands. Exchange RS(T) and QTH. SWL stations also may apply for this award on a heard basis. For special award, send QSL and $2.00 in US funds or 3 IRCs to: America Radio Club QSO Contest, PO Box 3576, Hialeah FL 33013.

YL ISSB QSO PARTY—PHONE

Starts: 0001 GMT February 19
Ends: 2359 GMT February 20

Two six-hour rest periods are required. Operating categories include: single operator, DX/WK partners, and YL/OM teams. All bands will be used and the same station may be contacted on different bands for contact points but not as country multipliers. VHF and UHF may be used but all contacts must be direct and not through repeaters. Nets are not allowed!

EXCHANGE:

Name, RS, SSBer number, country, W/K state or VE province, and DX/WK partner's call. If no partner, leave blank. If nonmember, send "NO NUMBER."

FREQUENCIES:

On HF, use the USA General-class band portions. On 20 meters, be aware of the nets on 14313 and 14336. Stay away from 14332; leave it open for DX members trying to make contacts. Check 80 and 40 meters on the hour.

SCORING:

Score 3 points for each member contacted on your own continent, 6 points if different continent. Nonmembers' contacts count one point. Only member station contacts count for multipliers. Multipliers are each state, country, and VE province. Also, each team contacted but only once for each team. When DX/WK partners contact each other it counts as a double multiplier. If your total dc input power is 250 Watts or less during the entire QSO party, then count an additional power multiplier of two. Final score is the sum of QSO points times the total multiplier.

AWARDS:

Special certificates will be awarded to the winners of each category. Regular certificates for country, US state, and Canadian province winners.

ENTRIES:

Logs must show date/time (GMT), station QSOed, RS, mode, band, SSBer number, US state, VE province, or country, and period of rest time. Summary sheets show states, Canadian provinces, countries, YL/OM teams, DX/WK teams, and partner contacts. Send logs and summary sheets to Rick and Minnie Connolly (K0RDJ and KA0ALX), Star Rt. 1, Crocker MO 65452 prior to June 1st. Be sure to indicate who your DX/WK partner is!

* = Multi-operator

2ND ANNUAL RTTY WORLD CHAMPIONSHIP CONTEST

Starts: 0000Z February 26
Ends: 2400Z February 26

SPONSORS:

73 and *The RTTY Journal.*

MISCELLANEOUS RULES:

The same station may be worked once on each band. Crossmode contacts do not count. Single-operator stations may work 18 hours maximum, while the multi-operator stations may operate the entire 24-hour period. Off periods are no less than 30 minutes each and must be noted in your log(s).

OPERATOR CLASSES:

(A) Single operator, single transmitter, phone only. (B) Multi-operator, single transmitter, phone only.

ENTRY CATEGORIES:

(A) Single band. (B) Allband, 10-80 meters.

EXCHANGE:

Stations within the continental 48 US states and Canada must transmit an RST report and state, province, or territory. All other stations, including Alaska and Hawaii, transmit RST report and consecutive contact number.

QSO POINTS:

1 QSO point is earned for each valid contact.

MULTIPLIER POINTS:

1 multiplier point is awarded for each of the 48 continental US states, Canadian provinces or territories, and DX countries worked on each band.

FINAL SCORE:

Total QSO points times total multiplier points equals claimed score.

CONTEST ENTRIES:

Entries must include a separate log for each band, a dupesheet, a summary sheet, a multiplier checklist, and a list of equipment used. Contestants are asked to send an SASE to the contest address for official forms.

ENTRY DEADLINE:

All entries must be postmarked no later than March 26, 1983.

DISQUALIFICATIONS:

Omission of any required entry form, operating in excess of legal power, manipulating of contest scores or times to achieve a score advantage, or failure to omit duplicate contacts which would reduce the overall score more than 2% are all grounds for immediate disqualification.

AWARDS:

Contest awards will be issued in each entry category and operator class in each of the US call districts and Canadian provinces and territories, as well as in each DX country represented. Other awards may be issued at the discretion of the awards committee. A minimum of 5 hours and 25 QSOs must be worked to be eligible for awards.

CONTEST ADDRESS:

Send an SASE to RTTY World Championship Contest, c/o *The RTTY Journal*, PO Box RY, Cardiff CA 92007.

Santa Rosa CA 95402

FROM EASTER ISLAND TO CHRISTMAS ISLAND

The Pacific adventures of DXpeditioner Eric Sjolund SM0AGD were mentioned in the August, 1982, edition of this column. The saga of how a copy of that column caught up with Eric reflects the hectic nature of his recent six-month journey.

Fellow Swede (SM5HIH—and how's *that* for a CW callsign!) picked up a copy of the August *73* while his ship was in Houston. SM5HIH sent the article to Eric Edberg W6DU, who maintained daily schedules with SM0AGD as the latter prowled the Pacific. W6DU fired the column off to Eric on Tarawa, in the Kiribati Islands. One month later, the letter arrived in Tarawa postmarked Taiwan and marked, "Not in Taiwan" Well, *some* of the letters are the same...

Meanwhile, Eric had completed his two-week operation from T30CB and was in Pago Pago in American Samoa. The letter containing the copy of the column was forwarded to Pago Pago, but once again Eric was on the high seas before the letter caught up with him, this time heading for Christmas Island. The letter missed Eric again at Christmas, but the next forwarding to Hawaii did the trick and Eric finally got to see the column mentioning his "forthcoming DXpedition" at the very end of that trip.

Your DX reporter caught up with world-traveler Eric on his way home to provide this update on one of the most successful amateur radio journeys in many years. Eric reviewed his odyssey for the benefit of *73* readers.

"After the International DX Convention in Visalia, California, I headed for Rarotango in New Zealand's Cook Islands to meet my yacht. We sent the generators and beam antennas ahead by air freight to make sure they would arrive on time, but they didn't show up. The skipper was anxious to leave, so we sailed to deserted Suwarrow Atoll, where I operated as ZK1AF.

"Before he died, a hermit had been the sole occupant of the atoll for years. I used the desk from his hut as my operating table, but I had to move it to the shore of the lagoon to get away from the trees around the hut. It was the most beautiful operating position on the trip: looking out over the long wire and Windom antennas stretched across the blue water. We made two more stops in the North Cook Islands, at the inhabited atolls of Manihiki and Pukapuka.

"I left my transportation in Fiji since the skipper was heading for New Zealand and would miss the other Pacific islands. I spent a month in Fiji looking for a yacht going in the right direction, while operating as 3D2DX. And although the island has no television, I received TVI complaints. It seems the neighbor's video players were sensitive to my low-band operations in the evening. Fortunately, the telecommunications official handling the problem was the person who issued my amateur license, and he took my side.

"It was just as well that I spent the time in Fiji. The poor propagation and solar flares would have made for frustrating DXing. I finally found a yacht heading north. I put T30CB on the air from Tarawa, where I stayed with a local ham, T30BY. I didn't feel guilty about spending a lot of time fishing and seeing the island, as T30 is not too rare.

"In Tuvalu I received my T2AGD callsign in a couple of hours and spent about a week operating. I was the only passenger on a seaplane to Wallis Island, but I had no trouble getting on the air as FW0AG.

"I finally caught up with my generators, TH2 beam, and transportation, and we sailed for Atafu Atol in the Tokelau Islands. This was my favorite stop on the entire trip; I only wish I had been there without radios. The island is unspoiled due to its lack of a good anchorage. The natives were extremely friendly, throwing feasts and dances in my honor. I had to explain that the pileups were waiting and I had to return to the radio. They all thought I was a bit crazy to sit and operate the radio all day and night. I never got to see much of the islands, and I think I would like to go back to really explore them, without a radio—or at least with only a very small one.

"After four wonderful days we sailed on to Kanton Island, the rarest spot on the trip. Kanton was once a military base, so old buildings and antennas abound. Unfortunately, I could not use the huge log-periodic antennas because we had no power to turn them.

"Kanton's two-dozen residents enjoy joint administration by the United States and Kiribati. Thus, I could use two callsigns: T31AD and SM0AGD/KH1. To reduce the confusion and to give out as many contacts as possible, I alternated callsigns, changing them daily at 2400 UTC. It was very confusing for me, so I hung up a sign with my call. At 2400Z, I would turn over the sign and change the call."

Eric Sjolund SM0AGD (right) recently completed a six-month DXpedition in the Pacific, making 47,600 contacts. Friend Eric Edberg W6DU (left) helped Eric stay in touch with Europe during the poor propagation last summer.

Eric's dedication to his DXing is evident in the impressive statistics he rolled up on Kanton: 19,000 contacts in six days of operation under each callsign. He worked 80 meters between 1100 and 1300 UTC, sunrise across the US, to give all operators their best chance to work him, even though this was the middle of the night in Kanton. In fact, Eric got by on only a couple of hours of sleep each night during his two-week stay. "There were no social distractions on Kanton," Eric relates, "but I did get a little tired the second week." Eric operated the radio nearly all the time he was on Kanton, except for a single afternoon that he spent bird watching.

Eric's last DXpedition stop was Christmas Island where he operated for six days as T32AJ. When he finally flew into Honolulu at the end of the voyage, he deposited his rig in a locker at the airport so that he wouldn't be tempted to turn it on.

After a week on the beach at Waikiki, Eric headed home for Sweden. Behind him he left thousands of pleased DXers. Among the 47,600 contacts were thousands of new ones and many more thousands from new-band countries. DXers from the 300-country level to the newcomer worked Eric, many at every stop. Even long-time DXers commented on the excellent handling of the pileups, saying that it was always a pleasure to work Eric.

"He gives everyone a fair shake; you know you will get through eventually, and he almost never misses a callsign, no matter how bad the pileup."

QSL CARDS

Those who made one of the 47,600 contacts with Eric will undoubtedly be looking for their QSL cards. So far, in my series on QSLs and QSLing, I have covered the design of the card, filling out the card, and mailing it to the proper person. Now let's look at the most fun part of QSLing: How do we get the card *back*?

If you are in a hurry (and who isn't?), the fastest way to get your return QSL is by sending a self-addressed, stamped envelope (SASE) with your card. Let's look at the finer points of using SASEs.

Your first step in preparing an SASE is to choose an appropriate envelope. The envelope should be large enough to accept standard-sized cards without folding; try a few of your larger cards first. If you are expecting a return card from outside the US, use an airmail envelope with the little colored slashes around the edges. In the place for the return address, put the call of the DX station.

Neatly address the envelope to yourself, including your callsign, and be careful to include "USA" at the end of your address. Use a separate envelope for each contact —or at least for each different callsign.

Hot Tip: Write the QSO information from your QSL card on the inside of the return envelope flap. For example: T30CB 13X82 0435Z 14003 kHz 2xCW 599. Then if the envelope gets separated from your card, the DX station or QSL manager can fill out and mail you a card based solely on the envelope.

If you are mailing your card and SASE to a stateside station or QSL manager, you can include a US stamp for return postage. (Watch out for postage-rate increases, and include enough postage to pay for the return.) But what if you're mailing your card to Eric's QSL manager, SM3CXS, in Sweden? You can't get Swedish airmail stamps at your local US post office, so how do you supply sufficient return postage? Most amateurs turn to the International Reply Coupon (IRC).

The tiny IRC has many mysteries of its own which we'll explore in a future column, but we'll keep it simple for now. In theory,

you can buy International Reply Coupons at any US post office. However, I have gotten a blank stare at some of the smaller branches when I asked for some IRCs. The cost of the IRC goes up frequently, but they were selling for $0.65 each at last count.

You might be able to purchase IRCs for less through your local radio club or from QSL managers and DX stations which receive a lot of IRCs. Ask around. A typical asking price might be $0.40 each, in lots of 100.

The International Reply Coupon forms a sort of internationally-recognized currency for hams. IRCs are seldom cashed in at a post office. Since each is worth one unit of international *surface* postage in exchange, you would get one $0.30 stamp for each IRC turned in. At $.65 each, this is quite a loss.

The IRC has several advantages in DX QSLing. It is universally recognized, even in countries where they are not directly useful, such as communist countries. Eastern Europeans, for example, cannot buy or exchange IRCs within their countries, but they can send out any they receive.

The chief drawback to the use of IRCs is their expense. Many operating aids for the DXer specify the number of IRCs necessary to return your envelope and QSL via airmail. This number ranges from 2 to 5, so it might cost as much as $3.25 in IRCs to get your card back from Sri Lanka, not counting the cost to get your card and return envelope *to* Sri Lanka.

Because of the high cost of IRCs and the poor exchange rate at the local post office, some DX stations suggest a "Green Stamp" instead of IRCs. No, not a real Green Stamp, but a US $1.00 bill. It costs less than 2 IRCs, is almost as universally recognized as the IRC, and usually is worth more in exchange. The money is certainly useful to the DX station and often is used to finance future DXpeditions.

However, "Green Stamps" have their own problems. First, they are easily lost or stolen before the money ever gets to the DX station. Also, some DXers question the ethics of asking for money, especially over the air. The ARRL will not accept QSLs from stations which *insist* on a cash "donation" for a QSL. But many stations "suggest" rather than insist on cash. Finally, a hoard of US dollars could get hams in some countries in trouble with the local authorities. If you are in doubt, stick with IRCs.

There is a third method of arranging for return postage for your QSL: Supply stamps which the DX station can use directly to return your card. In other words, if you send your card to SM3CXS, you put Swedish airmail postage on your envelope. All you need is a source of small quantities of mint airmail stamps from countries all over the world. You might try the local stamp and coin dealer, but he is unlikely to have much of a selection, and he'll want a stiff premium on what he does have. Wouldn't it be nice if some ham bought such stamps in quantity and packaged them for individual DXers?

Fortunately, someone has! Send an SASE (you know how to do it right, now) to DX Stamp Service, 7661 Roder Parkway, Ontario NY 14519, for their current price list.

The use of these stamps has several advantages. The cost is comparable to IRCs (and can be cheaper when 4 or 5 IRCs are required). The DX station returning your card does not have to dispose of the IRCs at a loss nor arrange to sell them. He doesn't even have to go to his local post office to buy stamps to return your card. He merely fills out your card, sticks it in the envelope, and throws it into the mailbox.

By making the QSL return so easy for the DX station, the QSL-return rate increases. And isn't that the point of this whole operation, to get your card back as quickly as possible? So try using the DX Stamp Service and see what it does for your QSL returns.

Next month we'll talk about QSL bureaus. Until then, good DX!

LETTERS

THANKS TO ALL

In response to the notice you put in the *73 Magazine* "Ham Help" column for me, requesting a schematic for a Philco 89 radio, I have so far had no fewer than 16 offers of help. I've written to each one thanking them and would like to say thank you to you, too. Hams are certainly helpful people!

Charles Owens
Durham NH

BOOTLEG COMMENTS

When the early morning hours of Monday, September 6th, produced some of the finest auroral curtain reflections I've ever heard on VHF (and a dazzling visual light show as well—one of the hottest ever seen in New England), I began to wonder how inexperienced or uninformed operators would react to this bizarre propagation phenomenon and its ghostly northern echos. Naturally, I tuned my receiver down to the illegal "bootleg band" (27.6-28.0 MHz) that lies between CB and ten meters for a first-hand look.

The band was hot with auroral reflection and my hunch was confirmed in spades! A hop across the band produced these howlers, which deserve to be logged for posterity:

From an unidentified source: "How come everybody in skipland sounds like they're gargling with Listerine? This has got to be the worst outbreak of bad breath I ever heard, 10-4?"

From a station in New Jersey: "O.K., Massachusetts, but there's 'lots of QRM from a station in North Carolina—he really be booming in *OFF THE BACK SIDE* (sic) of this here beam!!!"

From two stations in Maine: "10-4 on Old Orchard Beach...we're about 50 miles apart but you're peakin' off the ***BACK*** of the beam...I had to turn north to pull you in, and you're right dead off the back of the antenna. I don't know what to make of it."

The next time someone talks to you about the advantages of lowering or eliminating licensing standards for the amateur service, just reflect for a moment about the consequences of turning emergency communications services over to a gang of operators who don't even know which way to turn an antenna to work an auroral curtain—let alone (God help us!) the reasons why.

I've never had a heartier laugh, nor met a better argument for keeping licensing standards exactly as they are.

Dave Beauvais KB1F
Amherst MA

THANK BASH, WAYNE

I have subscribed to your magazine since 1977. In that time you have consistently vilified incentive licensing (something we WDs and KAs would not have thought to question). For the last year or two, you have been attacking the Morse code requirement. In your October, 1982, editorial, you demean Bash.

With at least the passive connivance of the non-hams running the FCC, Bash has given you exactly what you asked for. Incentive licensing is now a joke. (Wanna upgrade? Send a check.) I received a catalog in the mail last week which offered Bash tapes of the code tests. Now knowledge of Morse is irrelevant.

Wayne, where is your gratitude? Your sermonizing and lobbying just filled editorial space. Bash has accomplished your stated purposes. How can you attack him for that?

I don't believe incentive licensing has ever bothered newcomers to amateur radio. Incentive licensing irritated a bunch of geriatric AM operators by crowding them up the band among the sidebanders.

If the Feds ever caused a slump in new hams, it was probably by terminating Conditional licenses. The Bash hams of today are the sons of the Ws, Ks, and WAs who got their licenses by buying a new rig from the right guy.

I don't see how turning licensing over to radio clubs can be much of an improvement over the old Conditional system. I saw the Bash booth at the Cedar Rapids convention; there were enough people standing around, presumably licensed amateurs, to form a club.

Possibly hams could learn from the relationship the National Rifle Association enjoys with the Army. The military should be well funded for at least the duration of the Reagan administration, and it has a vested interest in rule 97.1(d). Today's armed forces, particularly the Navy and Air Force, have a far greater need for electronics and communications experts than for skilled riflemen. Reserve, National Guard, and ROTC units are conveniently located close to population centers and should be eager for a chance to show their best side to young electronics enthusiasts.

The FCC should be glad to give up the expense of the testing program, and the military should want a program that actually determines proficiency in electronics and communications skills.

Solon IA

INCENSED AND LICENSED

As a new amateur, I enjoy *73*—even bought a subscription. But after 2 issues I became incensed after reading comments from your other readers. Hams apparently are a big bunch of hypocrites when it comes to code and licensing.

The consensus—at least judging from your magazine—is that CW is:

1. A sacred cow: "I got mine, so everyone else must also suffer."
2. CW keeps yo-yos off the ham bands.
3. Every ham constantly uses CW.
4. Bash is destroying the tradition of hams for understanding radio.

Well, I say bull! First, if code is so sacred, then current hams would not mind taking a retest at renewal time to prove proficiency. Betcha a lot of Extra class would become Novice, maybe! At a recent ARS auction, the auctioneer, in selling a bug without success, asked if *anyone* uses CW. The laughter spoke for itself.

Second, it appears to me that the only ham bands that are crowded are the phone bands. The CW portion of all but the Novice bands are unused by comparison. And please tell me what General, Advanced, and Extra are doing on the Novice bands sending at 18-20 wpm with umpteen Watts?

Now to the test. The written FCC test is a joke. I studied a complete Heath course and the ARRL manuals, memorized all sorts of formulas, and flunked the test. The questions are ridiculous. My advice is to forget Bash, or whatever, peruse a manual or two, take and flunk the test, then study. The questions don't change.

Now that everybody is mad at me, I will make my recommendations for improving amateur radio.

1. Keep the code as a license requirement but set the General speed at 10 wpm. Nothing sacred about 13 that I know about. The single item keeping more people from becoming hams is $$$ for equipment. And require a code retest with every renewal. If that's too hard to swallow, set 10 wpm for Technician and grant phone on 40 and 80.
2. Expand the phone bands. An awful lot of our frequencies are wasted.
3. Restructure the written test to be a true evaluation of knowledge of radio telecommunications.

Pete Thacher N4HQZ
Raleigh NC

HABLA MORSE?

You're right on the mark regarding elimination of Morse code as a part of the amateur licensing process. What the FCC really ought to require is that all hams learn Spanish. You never know when someone knowing only Spanish could get into an emergency situation with only a phone-capable rig and couldn't remember any code (only time he used it was for the test).

Just the other evening I listened to two locals talking on two meters saying that we have to keep the screen tight and keep the code. Then they went on to talk about how they were working to upgrade and how nice the Bash books were. Who is kidding whom?

Drop the code and keep the written, but maybe print up 10 or 20 different versions to make it memory-proof. Contrary to the November editorial in *QST*, the time IS now.

Charles L. Kelsey WB2EDV
Mayville NY

LEARN TO EARN

Without going totally into the debate pro or con on the code requirement and justification for each question on the written exam, it appears to me that both have strong and weak points. I submit that anyone who has reasonable intelligence and desire can learn the code at 5 wpm. Whether 13 or 20 wpm should be required for phone privileges, I question. Also, the theory exam certainly has a problem. I think Bash is wrong to provide direct answers to the FCC questions! However, I think he is right in that some questions are ridiculous. The wording and content of some questions are outdated and would not lend themselves to the scrutiny of a first-year education major. Maybe H.R. 3239 will provide some change

for the better in these problem areas. Nevertheless, my main purpose in writing is to discuss learning the code.

I would like to share my experience at learning the code. This technique was used for both the 13-wpm General exam and the 20-wpm Extra exam. Now, I do not consider that I have much time available as I am a full-time employee (Texas Instruments), full-time father, full-time husband, and part-time student. Oh, yes, I do have a little time left over for a hobby. Also, I do not consider myself exceptionally bright (not a member of Mensa).

I purchased a battery-operated cassette tape recorder/player with earphone and a copy of the *73* 13+ wpm tape. Then I placed the tape player with pad and pencil on a table near my favorite chair. Each evening as I sat down to read or rest I would copy code for 10-15 minutes (at most). Very few evenings would I miss an opportunity to copy, however.

Using this technique, I passed the 13-wpm test on the first try after one month. On the 20-wpm test, I studied for six weeks and passed on the first try. I used only the *73* random character tapes and trained myself to copy only one letter at a time, responding to the composite sound. Also, I concentrated only on the code and did not prepare for the written (theory) exam. I prepared for that at a separate time after passing the code.

The very first hurdle is to decide that *you* are going to learn the code at the wpm required and dedicate some time to the project. Thus, the first problem is a psychological one. Also, you understand, no one is going to "give" you a passing grade—you earn it.

I consider the code as part of earning a privilege and it makes my license worth even more to me. Maybe code is outmoded and not modern, but like some of the theory, it gives me a taste for what is involved and the ability to use it when and if needed. Whether one needs to learn code at 20 wpm to get full privileges is questionable, but a good stiff theory exam seems appropriate. Let's keep the code, make it appropriate, and improve the theory exam.

Mike Grimes K5MLQ
Sherman TX

INSULTING

Reference my letter to you, published in the September, 1982, *73* ("Emergency Systems"). Your reply is, to say the least, oversimplified and insulting to my intelligence. I wonder how many IC boards you worked on and whose kids work on your equipment. If you can't give an intelligent answer to the problem, why waste space and time?

From all the comments on the CW issue versus comments on "Emergency Systems," it appears that there is no interest in the latter issue, and with your funny/useless/stupid comment, the problem will never be considered seriously. Of course, Wayne, there won't be any problems because the enemy will give us plenty of advance warning so we all can disconnect our antennas, and when your equipment gets blown away, you can find the kids to repair it.

I know you won't print this rebuttal to your stupid answer, but at least I got it off my chest. I most probably did a hell of a lot more equipment repair than you ever did. I can't find kids to do my repair work.

Good luck, Wayne. In your old age you are getting very sarcastic.

Arnold D. Samuels KH6COY
Ocean Shores WA

Old age may have made me sarcastic (no, I've always been sarcastic—it's just that you are getting old enough to recognize it at last), Arnold, and I don't doubt for a moment that I have insulted your intelligence. I also don't doubt that you've done a lot more repair work than I. I did train in the Navy and did the electronic repair on the USS Drum *during the war, keeping the radar, radio, and sonar running despite every effort of the submarine tenders to screw it up. And I spent ten years or so building ham gear for RTTY, sideband, and so on... managing to twist my hip permanently from standing on one leg at the workbench. But you're right—I've gotten away from servicing and even building, much is the pity, doing it only when there is no alternative. However, before I wrote my "funny/useless/stupid" response to the letter, I did my homework. If you do yours, in return, you will find out what I know... and that is that it is the youngsters who are the real hot shots at repairing today's circuits. The best service person we've ever had here was a teenager... and the worst were some older hams. The Drum is still around, so I did okay.—Wayne.*

SOFTWARE NEEDED

I don't have to tell you about the growing invasion of microcomputers into the ham shack. Many of your editorials show your awareness of this. I would, however, like to bring your attention to the expanding popularity of one computer in particular: the Commodore VIC 20. Many people don't realize how fast this machine's popularity is growing. For example, I know about nineteen hams who own computers. Out of these nineteen, two own the Heathkit H-89. One owns an Apple, two own a Radio Shack Color, five own Model 1s (Radio Shack), and nine own the Commodore VIC 20. And why not? The VIC 20 is an easily expandable computer with a fairly powerful Basic (CBM V2.0). Also, it is rf-tight. It's perfect for beginners in computing who are trying to learn and, right now, that is a lot of hams.

Unfortunately, there is one problem which, if let go too long, may cause the computer to be self-defeating. Because so many beginners are buying the machine, there is a shortage of good software. In fact, that is the one big reason many hobbyists may have for not buying the VIC.

Naturally, I don't want to see the death of such a fine computer. The solution to this problem, as I see it, is not so much to make available packaged software as it is for magazines, such as *73*, to publish software along with articles which explain how and why this software works. This would not only make software available but also would supply other VIC 20 owners with a better understanding of their computer so that they, in turn, could write programs to be published.

I have written a number of programs which would be of interest to hams, such as RTTY and Morse programs, programs which track OSCAR, etc. Also, many VIC owners don't realize how simple it is to interface a Model 33 ASCII teleprinter to their computer to serve as a line printer.

I'm sure that if you investigate this a bit further, you will find that printing this information could be profitable not only to amateur radio, but to *73* as well.

Jim Archer KF1T
Warwick RI

ANTI-SEMITIC?

In your November, 1982, editorial regarding how hard work pays off, you wrote, "given equal opportunity, the US would be as proportionately populated with wealthy Chinese as it is wealthy Jews."

I was shocked and surprised to read such an obvious anti-Semitic statement. Did you take a survey asking bank balances and religious persuasion? How about wealthy Catholics? Or wealthy Protestants? Why did you single out Jews? How in good conscience can you perpetrate this ugly myth and stereotype and in doing so inflame the fires of anti-Semitism?

As a former New Yorker, you must be aware of the many needy unfortunate Jewish families in the lower East Side of Manhattan. Did you take them into account in your survey?

Your point would have had the same effect if you had deleted "Jews" and substituted the word "people." By noting your comparison to "wealthy Jews," it showed you as a narrow, unthinking person who may profess to be free of bias but in reality is not.

Mike Herbstman KM2F
New York NY

While I've never been anti-Semitic before, I think in your case I might be able to make an exception. You, sir, appear to have a very serious inferiority problem. At any rate, I gather that you are trying to make a case that there is something wrong with being successful. Well, that's a good rationalization for your personal failure to be as successful as you feel you should. No, I'm not anti-Jew, anti-Chinese, anti-Catholic, anti-WASP, and so on, and I have thirty years of editorials to back me up... plus a wide range of personal friends of every known persuasion and color. I'm known, I think, not to be anti-Arab—which may taint me in your estimation. Now, I must admit that I do have my prejudices, being anti-drugs (which includes tobacco), anti-establishment (and most of you know what government agencies I am referring to), anti-laziness, anti-illiteracy... and so on. I have a strong record as being pro-success and I think I can point with pride to the intelligence and success of Jews, the Chinese (where they have not been screwed by the communist political system), and the Japanese.—Goy Green.

KEEP THE GOOD STUFF

QST and *Ham Radio* were my steady diet of amateur radio magazines for as many years as I care to admit—at least since the inception of *Ham Radio*. But in one way or another, these magazines changed (as magazines tend to do) and I became disenchanted. Being the inquisitive experimenter type, new excitement was needed. What seemed to have been lost, I found in *73*!

I like your editorial philosophy of including the type of articles in 73 which, according to some publishers, do not belong in amateur radio magazines. Hogwash! For example, one of these days (and sooner than most of us believe), the ham fraternity will have access to its own geosynchronous satellite, complete with microwave-band transponder! (See *Westlink Report*, September 10, 1982.)

Over the years, I have authored about 22 ham magazine articles, not the least of which was the popular coffee-can feedhorn (*Ham Radio*, May, 1976). In fact, in *73* for October, 1982, John Franke WA4WDL, says, "The first antenna I tried was the popular coffee-can horn. Since then it has become my standard to which all other antennas are compared."

Seeing testimonials like this from fellow amateurs gets my adrenalin pumping! Makes life seem worthwhile! But, alas, one can't have everything. I fear few persons know about the 1976 article or who authored it.

TVRO will never be the same since that article was published. You probably know that rectangular horns were the "in" thing originally, but not anymore. I like to think I should take a teeny bit of credit for that, too. It seems to me both the amateur and non-amateur stand to gain from articles of this kind; it works both ways.

Keep the good stuff coming. Maybe I'll even renew my *73* subscription! And I might even find time to write an article or two for *73*.

Norman J. Foot WA9HUV
Elmhurst IL

P.S. My consulting business is to a large degree an outcome of my amateur radio activities over the years. Your editorial covered such a possibility very well.

BEST ISSUE EVER

The November issue of *73* is the best amateur magazine I have ever seen—simply outstanding in its variety of construction projects. The power-supply project by WA6TTY is so good I can't believe it—even to an offer of help for an SASE! The step-by-step instructions are what are so sorely needed. I have, 2 years ago, written to *QST* and said that this is what we need, but I'm afraid the letter was given a stock reply and there it ended. But there are many of us who are not technical wizards who want to learn and construct. Well, Ken Wyatt has done a great service for us, and I do hope that you can encourage him to contribute again. How about a 66-foot 4- or 5-band cheap dipole—simple, yes, but isn't that what will get the new ham into making rather than buying? A cursory glance through the ham ads will show you how many hams buy their dipoles.

Well, anyway, if you never produce another issue for a year, the November issue is worth the annual price. Keep that up and let *QST* keep on with the dreary contest rules/winners/DX clubs, etc.

I could write pages of congratulations, I'm so pleased with that issue.

Eric Stabler VE3ISO
Ontario, Canada

HAM HELP

I need an original or photocopy of *TVI*, written by Dick Wildman W6MOG and published by *73*. I also need a DO-T35 or DO-T6 audio transformer, and I would like to buy MBD 201 or MBD 301 hot-carrier diodes in lots of 10. Please write and state your price before sending material.

Gordon La Grange W5AKQ
318 East Circle Dr.
Baytown TX 77521

I am a GI stationed in Europe and a soon-to-be Novice. I need a schematic for a Yaesu FT-401D (same as the FT-DX401). Also, can anyone tell me how to hook up my frequency counter to the FT-401 to measure the receive frequency? I will, of course, pay postage and copying costs for this information.

AWARDS

Bill Gosney KE7C
Micro-80, Inc.
2665 North Busby Road
Oak Harbor WA 98277

40-METER HOOT OWLS

There is another Hoot Owl network, which has been in existence since 1967. This net was started by W3CDH and others, meeting on 40 meters at 0600Z on Saturday mornings. Various frequencies have been used over the years but now they meet on 7.274 MHz, plus or minus QRM, and have check-ins from all across the country. To call in, merely say "hoot hoot," and after five regular check-ins, an award will be mailed to show participation.

The type of rig, power output, antenna system, or genus of operator has no bearing on the degree of Hoot Owl classification. Hoot Owl capability is based solely on the licensed operator's ability to stick with it on the 40-meter band at least two hours beyond his sensible bedtime.

An associate membership may be issued to operators who qualify in some respects but operate in the wrong frequency band or, for some other reason, fold up and are unable to hack it.

There's even an women's auxiliary! Any female stayer-upper attempting to qualify who is thereby hollered at by her father or husband shall be designated a "Mini-Hoot"!

Dues for the organization are $10.00, which keeps a Hoot Owl in good standing for a period of ten years. If not paid within the ten-year period, the former Hoot Owl becomes a "Chirp," which means he no longer gives a hoot.

Oh yes, the password, we must not forget that! Any Hoot Owl can easily be identified by another member when the password "hoot hoot" is injected at the point of contact. Do you give a hoot, or not?

CANADAWARD

The Canadian Amateur Radio Federation is pleased to announce the following awards available to all radio amateurs worldwide.

A colorful certificate will be issued to any amateur who confirms two-way contact with all Canadian provinces and territories. All QSOs must be on one band only. Separate awards are issued for each band on which the applicant qualifies.

Canadian provinces and territories include: VO1/VO2 Newfoundland/Labrador; VE1 Prince Edward Island; VE1 Nova Scotia; VE1 New Brunswick; VE2 Quebec; VE3 Ontario; VE4 Manitoba; VE5 Saskatchewan; VE6 Alberta; VE7 British Columbia; VE8 Northwest Territories; VY1 Yukon Territories. Note: VO2, Labrador, is part of the province of Newfoundland and therefore counts for a Newfoundland contact.

A mode endorsement is available if all QSOs are made on the same mode (CW, SSB, RTTY, SSTV). Contacts made after July 1, 1977, only will count for this award. All amateur bands may be used. Each distinct satellite mode (432/144, 144/29, or 144/432 MHz respectively) will count as a separate band.

To apply, submit the twelve QSL cards with $2.00 (Canadian or US funds) or ten IRCs plus sufficient funds ($.60) for return postage for your cards. CARF members need only send funds for return postage as the award is free to all CARF members.

A special plaque is available to any amateur who confirms two-way contact with all Canadian provinces and territories on each of five separate bands. Submit your 60 confirming QSL cards with $25.00 (Canadian or US funds) plus sufficient funds for return postage to: Canadawards, PO Box 2172, Station D, Ottawa, Ontario, Canada K1P 5W4.

WBCC AWARD

The Worked Broward County Cities award is sponsored by the Broward Amateur Radio Club. All amateurs are invited to apply for this very attractive and desirable certificate, printed in three colors on heavy parchment stock.

Applicants must obtain two-way contact with five of the Broward County cities. A gold seal will be awarded for fifteen cities worked.

All contacts must be made from the home QTH of the applicant; QSOs with mobile or portable stations in Broward are valid. All legal bands and modes may be used, but contacts via repeater will not be accepted.

Applicants should list the date, time, band, mode, and call and QTH of the Broward stations worked. Have this list verified by two fellow amateurs. Send your list, together with a fee of $1.00 and two first-class mail stamps (DX applicants send US $1.00 plus 3 IRCs), to: WD4RAF Awards Manager, 1921 NW 41st Street, Oakland Park FL 33309. Gold seals will be issued for a self-addressed envelope or one IRC.

The following Broward County cities apply: Coconut Creek, Cooper City, Coral Springs, Dania, Davie, Deerfield Beach, Fort Lauderdale, Hacienda Village, Hallandale, Hillsboro Beach, Hollywood, Lauderdale-by-the-Sea, Lauderdale Lakes, Lauderhill, Lazy Lake, Lighthouse Point, Margate, Miramar, North Lauderdale, Oakland Park, Parkland, Pembroke Park, Pembroke Pines, Plantation, Pompano Beach, Sea Ranch Lakes, Sunrise, Tamarac, and Wilton Manors.

THE VK5 WHISKEY CHARLIE AWARD

This award was originally created to commemorate 25 years of the club's existence and is still an award hunter's challenge.

For the first 23½ years of VK5WC's existence, it was the only callsign authorized from Woomera, a now small Australian community and former home to the European Launch Development Organization (ELDO). The club presently has four active HF members with several other members awaiting their reciprocal calls. VK5OL, VK5MQ, VK5AH, and VK5LA can be heard operating from the village as well as the club's station itself.

The award is available to all licensed amateurs throughout the world who can show proof of two-way contacts with club station VK5WC and two club members, or four different Woomera stations who are club members.

Any authorized frequency or band, including crossband and VHF, UHF, or satellite repeater, and any mode or combination of modes for which the stations concerned are licensed are permissible. Contacts may be claimed retroactive to May 3, 1978, which is the date the use of individual callsigns was authorized within the Woomera village community.

To apply for the award, submit a copy of all eligible log entries signed by the claimant and certified by either the cosigning of two other licensed amateur radio operators or, in the case of an isolated claimant, certified by a justice of the peace or a notary public. In case of dispute, local log entries at Woomera shall be accepted as proof conclusive of whether or not a contact took place.

Claims for the award are to be submitted in writing to the Award Manager, Woomera Amateur Radio Club, PO Box 538, Woomera, South Australia 5720, Australia, accompanied by $2.50 in Australian currency (or equivalent), preferably by bank check payable to Woomera Amateur Radio Club, Award Account.

The award is an enlarged version of the club's QSL, with black, red, and blue printing.

WORKED VK8 AWARD

Work or hear eight stations in the VK8 area, irrespective of applicant's QTH. Any band, any mode, GCR applies. Award fee is $3.00 Australian or ten IRCs. Send log data with fee to: Awards Manager, PO Box 40318, Casuarina 5793, Northern Territory, Australia.

TASMANIAN DEVIL AWARD

Applicants must establish contact with a number of VK7 stations depending on their QTH: Australia, 50 contacts; Oceania and Antarctica, 30 contacts; Asia and North America, 20 contacts; Europe and South America, 10 contacts; Africa, 7 contacts. Band and mode endorsements are available as well as special endorsements for making all contacts with Novice stations.

Claim logs with applicant's call and full name are to show station contacted, date, time, band, and mode. The claim is to be signed by the applicant and countersigned by two other amateurs. Spot checks will be made with contact stations in VK7 for confirmation. QSLs are not required. Contacts made on or after January 1, 1978, are valid. The award fee is five IRCs or equivalent for Australian applicants, ten IRCs for overseas applicants. Apply to: Tasmanian Devil Award, VK7 QSL Bureau, PO Box 3710, Hobart 7001, Tasmania, Australia.

ZONE 29 AWARD

To qualify for this award, it is necessary to contact 25 amateur stations located in zone 29. Zone 29 includes the VK6 and VK8 call areas. Only contacts after 0800 GMT on January 1, 1952, are valid. No crossband contacts are permitted. Minimum acceptable exchange of reports is RS33 or RST338.

QSL cards are not required as proof of valid contacts but the applicant must show that the log extracts have been examined and verified by two other amateurs. A simple declaration that the applicant's station has conformed to all licensing regulations related to his operation is mandatory.

The fee for the award is $1.00 Australian or five IRCs. Apply to: Awards Manager, Zone 29, WIA (VK6 Division), PO Box N1002, Perth 6001, Western Australia, Australia.

THE VK1 AWARD

This award is available to any amateur or SWL who submits details of valid contacts with the required number of VK1 stations. On HF, VK stations require 20 VK1 contacts, others require 10 VK1 contacts. On VHF, 10 VK1 contacts are required.

A log extract is required, showing for each contact claimed the GMT date and time, band, mode, callsign of the station worked, and reports or cyphers exchanged. SWLs must show callsigns of both stations in the QSO and the reports or cyphers given by each station. The award cost is $2.00 Australian or five IRCs. Applications should be forwarded to: Awards Manager, WIA (VK1 Division), PO Box 46, Canberra 2600, Australian Capital Territory, Australia.

THE SOUTHERN CROSS AWARD

This award is granted to amateurs and SWLs who obtain the required number of points from working or hearing members of the Eastern and Mountain Districts Radio Club of Melbourne, Victoria. To qualify, Australian amateurs and SWLs require fifteen points, New Zealand amateurs and SWLs require ten points, and all other amateurs and SWLs require five points.

A point is awarded for each club member worked or heard. The club callsigns VK3ER and VK3BNW each count two points, but only three points can be claimed if both callsigns are included in any one application for the award.

The award will be issued for multiband and multimode or specific band or mode as requested at the time of application.

To obtain the award, a General Certificate Log and the award fee of $.50 Australian or three IRCs should be sent to: Awards Manager EMDRC, PO Box 87, Mitcham 3132, Victoria, Australia.

The General Certificate Log Rule means that any officer of a recognized amateur radio club or society, any two licensed amateurs, or any CHCer may certify a copy of the applicant's log. In this way, you do not have to submit your original log.

THE NAVAL POSTGRADUATE SCHOOL AMATEUR RADIO CLUB

The Naval Postgraduate School Amateur Radio Club in Monterey, California, will operate a special-event station K6LY during the 42nd Bing Crosby National Pro-Am Golf Championship. The station will be located near the eighteenth green at Pebble Beach. Operating hours will be 1800Z-2400Z daily, February 3-6, 1983. K6LY will operate on the lower part of the General class phone band on 15 & 40 meters. Stations contacting K6LY and wishing to receive a commemorative Crosby Pro-Am QSL card should send their QSL card to WB6ZSB, 831 Avalon Place, Monterey CA 93940. An SASE is not required.

NORTH OKANAGAN RADIO AMATEUR CLUB

We of the North Okanagan Radio Amateur Club are going to be having a special station set up during our winter carnival again this year. Our station will be operating during the week of February 4-13, 1983, from 2100Z to 2400Z, daily. The frequencies that we will be on are 28.575, 21.375, and 14.295, plus or minus QRM. The cost of our award is either $1.00 or an SASE sent to North Okanagan Radio Amateur Club, Box 1706, Vernon, British Columbia V1T 7T9, Canada. This award, called the Vernon Winter Carnival Award, is available year round by working our club station (VE7NOR) or 3 Vernon area stations. The Vernon area is defined as Vernon, Armstrong, Winfield, Oyama, Lumby, and Enderby.

DEALER DIRECTORY

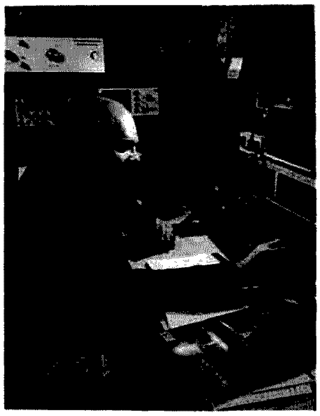
NEVER SAY DIE
editorial by Wayne Green



THE CONNECTICUT CONTEST, CERTIFICATE, AND CHOWDERHEAD CLUB

There are three items on my agenda which may be of less than great importance to you. One has to do with some wondrous changes wrought by the International Amateur Radio Union, wherein, I was told by several of the assembled at the recent Bangkok hamfest, the ARRL was finally dumped out of the driver's seat. There was an unseemly amount of rejoicing among our supposed friends overseas.

While the League has graciously permitted foreign amateur radio societies to belong to this illustrious organization, HQ always insisted that they have complete control of it. Unrest has been brewing for quite a few years over this, with a growing number of malcontents fomenting revolution over the high-handed, low-action management by the League.

Oh, there goes that miserably crotchety old Wayne Green, griping about the League again... right? Well, you probably believe in the Tooth Fairy, too, so who am I to suggest you take off your smoked glasses and see what your bumbling voting record at ARRL elections has cost you. But, if you even have a shred of question about how our beloved League is perceived overseas, then for heaven's sake try to find your old rig up there in the attic and get on the air for a day or two...make some DX contacts ...and, after you've gone through all the usual drivel ...probably mercifully covered up by QRM...ask 'em what they think. You'll get an earful from a bunch of 'em.

At any rate, there was general rejoicing at Bangkok over the freeing of the slaves as news of the vote to move IARU headquarters from some almost totally unknown town in Connecticut to Geneva was spread. Who knows, perhaps the IARU will now be able to develop some clout!

Item two has to do with the recent director election wherein Mary Lewis eked out a win by less than ten votes...raising hell with the morale of the entrenched chauvinists at HQ. They'd said for years that, dammit, this was a man's hobby and they didn't need any women on the board of directors. One ex-president of the outfit said that hell would freeze over before they'd let a woman get on the board. I wondered about that, so while in Bangkok I made a visit to Hell (a well-known Bangkok restaurant) and found that it had not, in fact, frozen over. Well, so much for ex-presidential predictions. No wonder they dumped him.

Then there was the defeat of poor Don Miller out in Indiana. Don has had a rough time of it. First the HQ gang did all they could to keep him from being elected the first time. Then they trumped up a bunch of baloney and scared him into resigning, threatening to put on the pressure to get him fired from his job. Knowing that HQ had been able to get Mary's job, he panicked. With Dannals and Baldwin out of the driver's seat at HQ, Don apparently thought he might be able to make it back into the director's chair again. Well, one thing no one at HQ wants to have to live with is a director who starts asking questions and shows any initiative at really directing. They have their short yearly meeting, vote on everything unanimously, and go home. Do not rock the boat, please. Remember that we here at ARRL are all one happy family and that Wayne Green is a kook. Close, but no cigar...actually I'm a cook...love to cook.

So Metzger is your Midwest Director and those who voted for this chap are welcome to him. Some of the other directors like him, others sneer and call him a toadying turkey. That sort of talk is ill-becoming of directors, even if it might be true. I try to look at the bright side...the more all this politics screws up the League, the more interesting things I can write about.

Since most of the older timers at the League have bailed out, the attitude has improved a bit. The old-timers' perception of the membership was as a bunch of nitwits who could easily be led into anything they wanted. Unfortunately, there was more truth in this perception at times than was comfortable. For every thinking ARRL member, there was a counterbalancing group of blind followers, eager to buy whatever the latest party line demanded.

The laughter was uncontrolled at HQ when they came out with incentive licensing. This was their plan to disenfranchise 85% of the hams from the phone bands, returning us to the pre-WWII licensing system of two classes, one with phone bands and the other without. Would you believe that almost 50% of the ARRL members bought the idea ...mostly on the basis of the nice name they'd given it. Who could be against *incentive* licensing? Only those who bothered to read the fine print, which turned out to be a minority. And a lot of those opposing it were fighting it because they didn't want to have to go down and retake the test all over again rather than because the whole idea was ridiculous.

The few firms still left in the amateur radio industry are waiting to see some positive moves by the new management of the League. There's not much left of the industry any more. 95% of the manufacturers are long gone...and 95% of the dealers are gone. We used to

QSL OF THE MONTH

This month's winning QSL is from Lutz Hannig DL9GI of Berlin, West Germany. Lutz's unique design depicts a confused-looking Red Baron flying into the center of a multi-colored radio wave. The card cleverly focuses your attention to the center by moving from the black background to the bright yellow and red of the middle. The rapid shift in hue lends depth to the scene, making it appear as if the aviator were flying into the maw of some great creature. Lutz's callsign, emblazoned in white at the bottom, ensures that the viewer knows where this card is from.

If you would like to enter our QSL card contest, put your QSL in an envelope with your choice of a book from *73*'s Radio Bookshop and send it to *73*, Pine Street, Peterborough NH 03458, Attn: QSL of the Month. Entries which do not use an envelope or do not specify a book will not be considered.

have nearly a thousand ham dealers around the country selling *73* over their counters! Now there's a few score. You know this when you look around for some place to go to see a new rig. A few years ago, ham stores were almost everywhere... today they aren't. There's just one or two left in all of New England, for example.

THE CODE

Which really brings us to a discussion of the Morse code. Just what you really wanted, eh? Yes, I know the League is dedicated to preserving the code. And, believe me, I have heard all the old saws about the code being the only thing protecting us from the hordes of CBers and keeping the ham bands from being like the CB bands. What a crock of...er...stuff. Frankly, I'm not at all convinced that if we set up booths on the street and gave away ham tickets to any passerby, we could attract anyone to our hobby.

There is now a rising call for getting older people into amateur radio, our having failed to interest kids any longer. Just what we need. Sure, the hobby is great for oldsters. It would keep them from getting lonely. It would give them something to do in their twilight years...kerchunking repeaters and jamming nets. Why save all that fun for just the Extra-class hams, eh? Of course, we aren't going to provide our country with much in the way of technicians, engineers, and scientists this way...or electronic fodder for our war machine, should we decide to save the world for capitalism again. But we would be able to sell some rigs, thereby enriching the lives of the Japanese manufacturers. I say let's get at it. Let's get into the old folks homes and set up club stations...give licensing classes ...and call in Bash so faltering memories won't even have to learn any theory.

Word from the underground has reached me that the outfit selling the FCC Morse-code exams at Dayton was run by none other than a very well-known California ham. We really have to see that those tapes get better distribution so that old people, who have more trouble than kids with the code, are not discriminated against. Why should we penalize old people just because they can't learn the code?

As a matter of fact, if we are going to go along with the modern morality, we should set up a system whereby anyone who has shown proof that he has seriously tried to learn the code, yet failed, would get a license. In today's world, it is not the answer to the question

RTTY Tuning: The New Solution

This simple tuning indicator whipped the competition and took first place in 73's Home-Brew II Contest.

What is your favorite method to tune in a radioteletype (RTTY) signal quickly and accurately on an SSB receiver? A dual ellipse on an oscilloscope? Light-emitting diodes (LEDs) activated by mark and space filters? A signal-strength meter? By ear? Here is a new one that might make you change your mind.

Background/The Problem

When Teletype® signals are sent through audio channels, they are usually conveyed by switching between two tones with a different timing pattern for each of the characters. During periods when no characters are being sent, a steady tone, called the "mark" tone, is present. The other tone is called the "space" tone. A device called a "terminal unit" (TU) extracts these two particular tones from any background noise and produces a digital signal suitable for a printer or computer.

If this audio signal is coming across a telephone line or an FM radio link, the frequencies of the tones at the receiving end will be the same as at the origin. However, there can be a problem when using an SSB receiver, because a slight mistuning will change the frequencies of the tones heard and the terminal unit will not work. Over the years, various methods have been devised to indicate when the proper tones are detected. Here is a new one.

A New Solution

As shown in Photo A, the circuit displays its output with a row of 20 LEDs. Each one will light up when the strongest audio frequency present is within its particular range. The two with the pointers over them correspond to the mark and space tones. A constant mark signal is tuned properly when the LED under the left marker is lit. When characters are being received, the LEDs under both markers will be lit. If the tones are low in frequency, LEDs to the left of these positions will be lit. Higher frequencies activate LEDs farther to the right. It's as easy as tuning an FM broadcast receiver with a tuning meter!

Theory of Operation

The simplified block diagram in Fig. 1 illustrates the basic principle involved. Each time the input signal completes a cycle, the current content of the counter is captured in the latch. After a brief delay, the counter is reset and resumes counting for another cycle of the input signal. Meanwhile, a decoder is looking at the output of the latch and selects one of the LEDs based upon it.

For example, let's suppose we had a clock of 200 kHz and an input signal of 2 kHz. During each cycle of the input signal there would be 100 clock pulses, so the counter would contain 100 when the latch grabs the counter's output. If there was an LED corresponding to a count of 100, the decoder would cause it to light up until a different count was obtained from the counter. A higher frequency input would result in a shorter period, a smaller count, and a different LED.

Keeping this simplified model in mind, let's look at the actual circuit (Figs. 2 and

Photo by Mark Hood

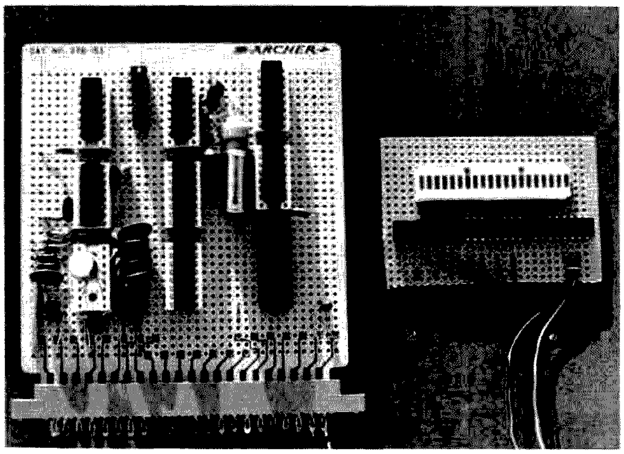

Photo A. Appearance of the display for a correctly tuned signal.

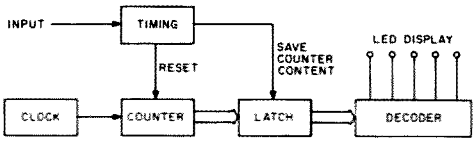

Fig. 1. Simplified block diagram.

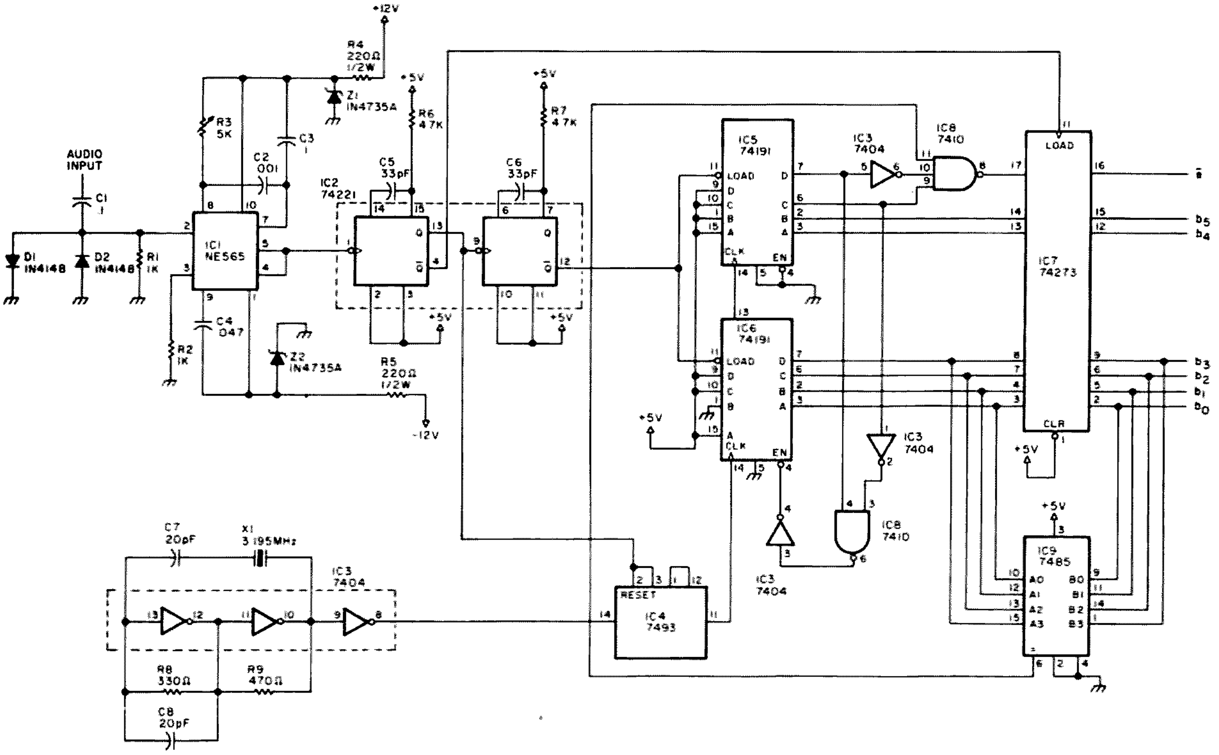

Fig. 2. Main circuit for tuning indicator.

3) and see how it differs. Starting from the audio input on the left, the first thing you will notice is the 565 phase-locked loop. I initially tried some experiments with bandpass filters and a Schmidt trigger. This worked great with a nice clean waveform from a signal generator, but was pretty useless with a noisy signal from a sideband receiver. The phase-locked loop does a good job of following a signal through the noise and providing a nice clean square wave of the same frequency for later logic circuits. The two diodes before it provide protection against large signals that could damage the IC.

Next we have a couple of one-shots (IC2) to generate timing pulses at the end of each cycle. Four separate steps are involved: (1) Stop the clock so the count isn't changing during latching. (2) Capture the contents of the counter in the latch. (3) Reset the counter. (4) Restart the clock.

When the counter is reset, it is set to −3 rather than zero as you would probably expect. (See pins 9, 10, 1, and 15 of the counters.) This is to make the mark and space tones fall in the middle of the frequency ranges for the corresponding LEDs.

When the most significant bit of the count (IC5, pin 7) is 0 and the next bit (pin 6) is 1, the count is in the range of 64–127. This is the region where the display is enabled. If the counter content reaches 128, IC6 is disabled through pin 4 and counting stops. This prevents overflowing and a false display for a very low frequency input.

Under the latch (IC7), you will notice a 7485 magnitude comparator. Each time the latch is clocked, it compares the counts for the current and preceding cycles. When the low-order four bits are the same, the display is enabled for the next cycle. This blanks the display during changes, resulting in a much cleaner appearance and dimming with only noise present. High-order bits could also be compared with another chip but I doubt it would have much effect because counts for consecutive cycles differing by a multiple of 16 are probably quite rare.

Fig. 4. Basic program to compute crystal frequency and counter preset for given mark and space tones.

Construction and Adjustment

As shown in Photo A, the LED displays and three decoder chips are mounted on a small piece of perfboard which can be installed on the front panel of a terminal unit. The rest of the prototype was constructed with wire wrapping for ease of modification during development. You can reduce the cost by using solder-tail sockets with point-to-point wiring or making a PC board.

With no input applied to the circuit, adjust R3 so that the LED just to the left of the center line is lit.

Power requirements are + and −12 volts at about 25 milliamps and 5 volts at about 350 milliamps.

Modifications

The crystal frequency and counter preset value shown in the schematic are for the standard RTTY tones of 2125 and 2295 but can easily be changed for a different pair of tones in the same neighborhood. The Basic program in Fig. 4 computes these values from

Obtaining Parts

The only unusual components in this device are the 10-segment LED bar-graph displays. As indicated in the parts list, these are available at your local Radio Shack store. If there is not a Radio Shack in your part of the world, use 20 separate LEDs instead.

I happened to use a crystal in an HC6/U holder. If you don't mind the size and appearance of an FT-243 holder (like Novices used in the old days) you can save a couple of bucks by getting a crystal with only .01% tolerance which is still more than adequate.

Everything else is quite ordinary and available from various dealers who advertise in the back of *73*. The circuit is not at all critical and minor substitutions should not affect performance.

CES INTRODUCES THE NEW 510SA "SMART PATCH"

The State of the Art Simplex Interconnect

Communications Electronics Specialties introduces the CES 510SA "Smart" Simplex Autopatch, with many important new features never available before: • Three digit control codes with user programming. • A sophisticated toll restrict provides positive long distance lock out. • Time-out and COR activity timers with warning beeps and digital programming. • Rotary or DTMF dialing. • Phone line in-use detector prevents interrupting a call in progress, and sends unique CW sequence. • Phone ring detection logic enables unique CW sequence. • Digital programming of the sample rate and width, and noise gate sensitivity control, for easy interfacing with most radios. Simple and direct connections to radio.

Options available: • Smart CW identifier with unique CW messages for each patch function. • FCC type accepted phone line coupler. • Special tone squelch kit to operate patch through repeaters.

Fig. 5. Output of program in Fig. 4 for standard tones of 2125 and 2295.

Use and Conclusion

The circuit requires a minimum of 10 millivolts peak-to-peak for good tracking of the input signal. Acceptable results can be obtained by connecting the tuning indicator directly to the receiver's speaker, but a cleaner signal will produce a more pleasant display. If your terminal unit has a bandpass filter, connect this circuit after the filter, but before the limiter. If you don't have a bandpass filter, I suggest that you build one (see *73*, September, 1977, page 38) or buy one such as the Flesher PS-170. It's simple, inexpensive, and makes a big difference when trying to copy RTTY under noisy conditions.

For a couple decades, most people agreed that a dual ellipse pattern on a CRT was the best way to see when a RTTY signal was tuned in properly. Try this circuit and you might not be one of them anymore. ■

Uncover Equipment for OSCAR Phase III

Lurking in flea markets and junk boxes is everything you need to work OSCAR. K6KLY tells you what to look for and how to make it work.

R. Bentson K6KLY
3432 Lodge Drive
Belmont CA 94002

This article is for the amateur who wants to get on OSCAR Phase III inexpensively. This can be done by converting a surplus GE UHF transmitter strip to a 435-MHz SSB mixer.

With the upcoming launch of OSCAR Phase III, I was looking for a way to get on the 435-MHz input inexpensively when I found some old GE Progress-line UHF transmitter strips at a ham flea market. I asked a friend who had a GE data file to send me a copy of the schematic, which he did.

After reviewing all the material he sent me, I found that I had a 450-to-470-MHz transmitter, model 4ET24A2. It could be modified to be a mixer for 435 MHz, but it would be upconverting in frequency with the local oscillator frequency on the high side of the wanted output-signal frequency. Thus, the sideband signal would be inverted and when I wanted to change frequency in an upward direction on 435 MHz, I would have to go down in frequency with the 28-MHz exciter.

This was too confusing to try to handle while tracking a satellite, so I looked further and found in the data my friend sent me a schematic on a unit, model 4ET24A1 or A11, which covered 406 to 420 MHz. This was perfect. When you want 435 out and you are putting 28 MHz into a mixer, you need a 407-MHz local oscillator to make the mixer work correctly. This 4ET24A1 was in the right frequency range. I started looking around at the swap meets and asking my friends who were into old FM equipment to keep an eye out for this model for me. I found out later that GE did not make too many of these A1-type strips as compared with the A2-type strips. I finally found a 4ET24A1 strip at an FM-equipment auction and paid $20 for it, complete with all the tubes.

After cleaning the dirt off the unit and making sure it had not been modified or robbed for parts, I started the conversion. My first task was to order a crystal from the ICM crystal company in

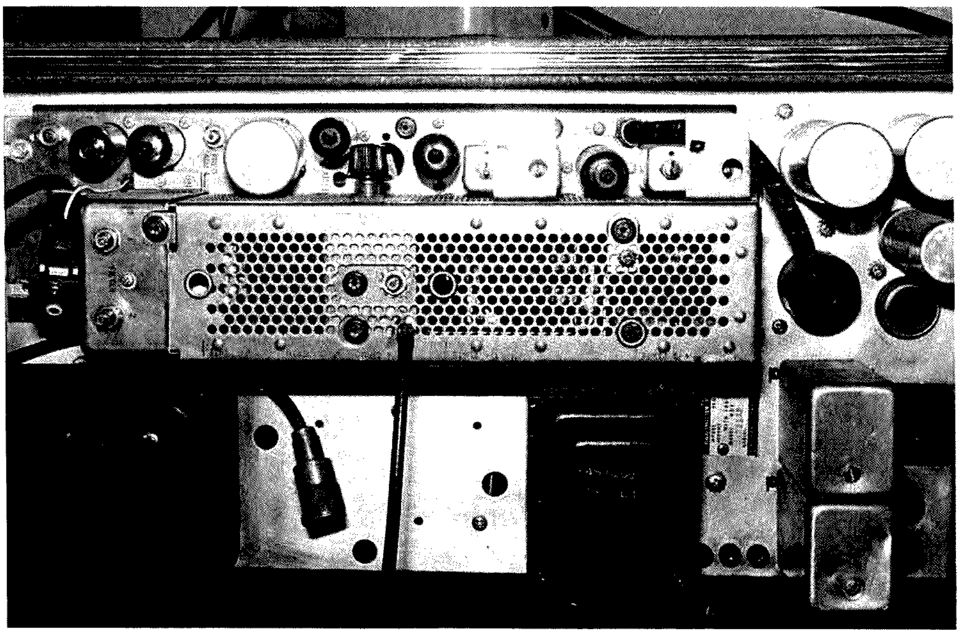

Photo A. Overall view. Notice orientation of the crystal oven.

Oklahoma City. Since we need a 407-MHz local oscillator and the transmitter strip has a multiplier of 36, the crystal frequency needed is 11.3055 MHz. When ordering the crystal, tell ICM that the crystal is for a GE model 4ET24A1. If your strip has a crystal oven or if you can get a GE crystal oven, tell ICM that the crystal will be used in a GE oven.

Modification

The modification of the transmitter strip is very easy. First, remove the cover over the three large tubes in the caged-in area. This is done by removing one screw next to the MULT-4 test point (see Photo A). Next, pull off the cover, starting with the end over the 2E26. The far end of the cover fits under a notch in the output filter. Then, find C171, the PA grid-tuning capacitor of the last tube, a 6907. Drill a 3/16" hole in the plate that C171 is mounted on, halfway between C171 and the edge of the plate closest to the red test point, PA CATH (see Photo A). Next, using a small pair of wire cutters, cut off the capacitor and wire going to pin 4 of the 6907 tube. Pin 4 is right under C171.

Prepare a three-foot length of RG-58-type coax by stripping off 2 inches of the outside rubber jacket, followed by one and one half inches of the coax braid. Next, remove ¼ inch of the inner insulation from one end of the coax. Prepare the other end of the coax to accept a PL-259 coax fitting with the adapter ring for the RG-58 coax. Push the center conductor of the coax through the 3/16" hole in the plate and then wrap and solder the center conductor to pin 4 of the 6907 tube under C171. Push the coax braid down around the 3/16" hole and solder the braid to the plate.

Find the cover and, using a reamer or a set of drill bits, enlarge the vent hole in the cover that is closest to being right over where the 3/16-inch hole is in the plate when the cover is replaced. Enlarge this hole to about ¼ inch, which is big enough to allow the coax to pass through it. Feed the coax through the hole and replace the cover on the cage.

Solder a PL-259 with the adapter to the end of the coax cable you prepared earlier. Find a 28-MHz rf choke coil such as a Miller RFC28 or Ohmite Z28. Solder this rf choke inside another PL-259 coax fitting. One end of the rf choke goes to the center pin of the PL-259 and the other end goes to the outside rear edge of the PL-259. Using a UHF coax T-fitting, connect the new cable from the mixer unit and the coax fitting with the rf choke inside it to the T-fitting. Later, the coax from the 28-MHz exciter will connect here also.

Caution: The rf choke must be connected or damage could result to your exciter. Check the rf choke with a VOM to be sure it is good, after soldering to the PL-259.

Locate the socket the crystal oven plugs into and cut off the ground wires going to pin 5. If there are any other wires going to pin 5, cut them off pin 5 also and solder them to ground points. Next, remove V108, a 12AU7/6680 tube. It will not be used. If any other tubes are missing, replace them per the following list:

V101	6BH6/6661
V102	6U8
V103	6CL6
V104	2E26
V105, 106	6907/6252
V107	12AU7/6680

Install the crystal in the GE oven between pins 4 and 8; then plug the GE oven into the 8-pin socket on the mixer. If an oven is not used, plug the crystal into pins 4 and 6 on the 8-pin socket.

Power Supply

Power supply connections are as follows:

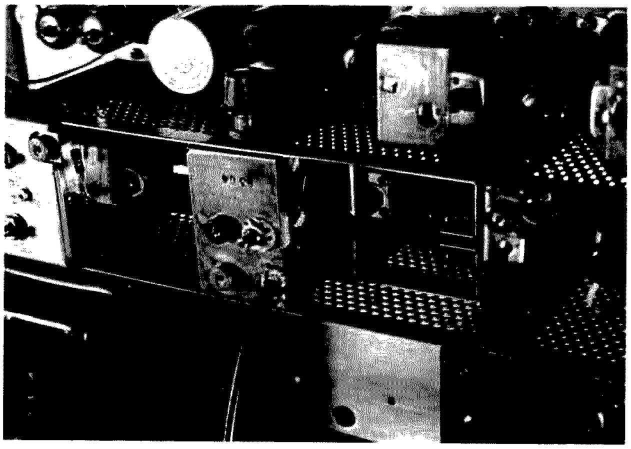

Photo B. The coax from the 28-MHz exciter is soldered to pin 4 of the last 6907 tube right under the variable capacitor, C171.

- Pins 1 and 2 are not used. Audio input for FM.
- Pin 3 to ground. Oscillator-select channel 1 on A11 model.
- Pin 4 is not used. Oscillator-select channel 2 on A11 model.
- Pin 5 to +6 volts dc keyed on transmit, if antenna relay is used.
- Pin 6 to 6 volts ac or dc filament supply (not used if 12-volt filament supply is used).
- Pin 7 to ground (filament-return lead for 6-volt filament). (To 12 volts ac or dc if 12-volt filament supply is used.)
- Pin 8 bias supply, −22 volts dc, adjustable.
- Pin 9 B+ final, 450 volts dc, keyed on transmit.
- Pin 10 B+ multiplier, 300 volts dc, keyed on transmit.
- Pin 11 B+ oscillator, 200 volts dc.

This transmitter strip is normally used with a GE model 4EP4A power supply. This is the same supply that is used on GE Progress-line repeater stations. Since many older 2-meter and 440-MHz repeaters are going to solid-state equipment, some of these power supplies are showing up at auctions and flea markets now. The 4EP4A power supply is selling for about $30 to $40 in working condition. See the photos of the completed mixer mounted on the power supply to help you recognize the power supply at the flea markets.

When using the 4EP4A power supply, the bias-supply section will need to be modified to a voltage-multiplier-type power supply in order to get the required −22-volts-dc bias. See the *ARRL Handbook* under power supplies for circuits. This requires only the addition of two capacitors and two diodes.

Here are the terminal-strip connections on the 4EP4A power supply:

- Terminals 1, 2, and 4: not used. Audio lines.
- Terminal 3: key to ground on transmit PTT line.
- Terminal 5: 250 volts dc "caution."
- Terminal 6: to ground channel A select on model A11.
- Terminal 7: ground.
- Terminal 8: 6.3 ac filament line.
- Terminal 9: one side of 110-V-ac input.
- Terminals 10 and 11: other side of 110-V-ac input.
- Terminal 12: not used. Channel B select on model A11.
- Terminal 13: not used. Transmit light line.
- Terminal 14: not used. Rec mute line.
- Terminals 15 and 16: not used. Spares.

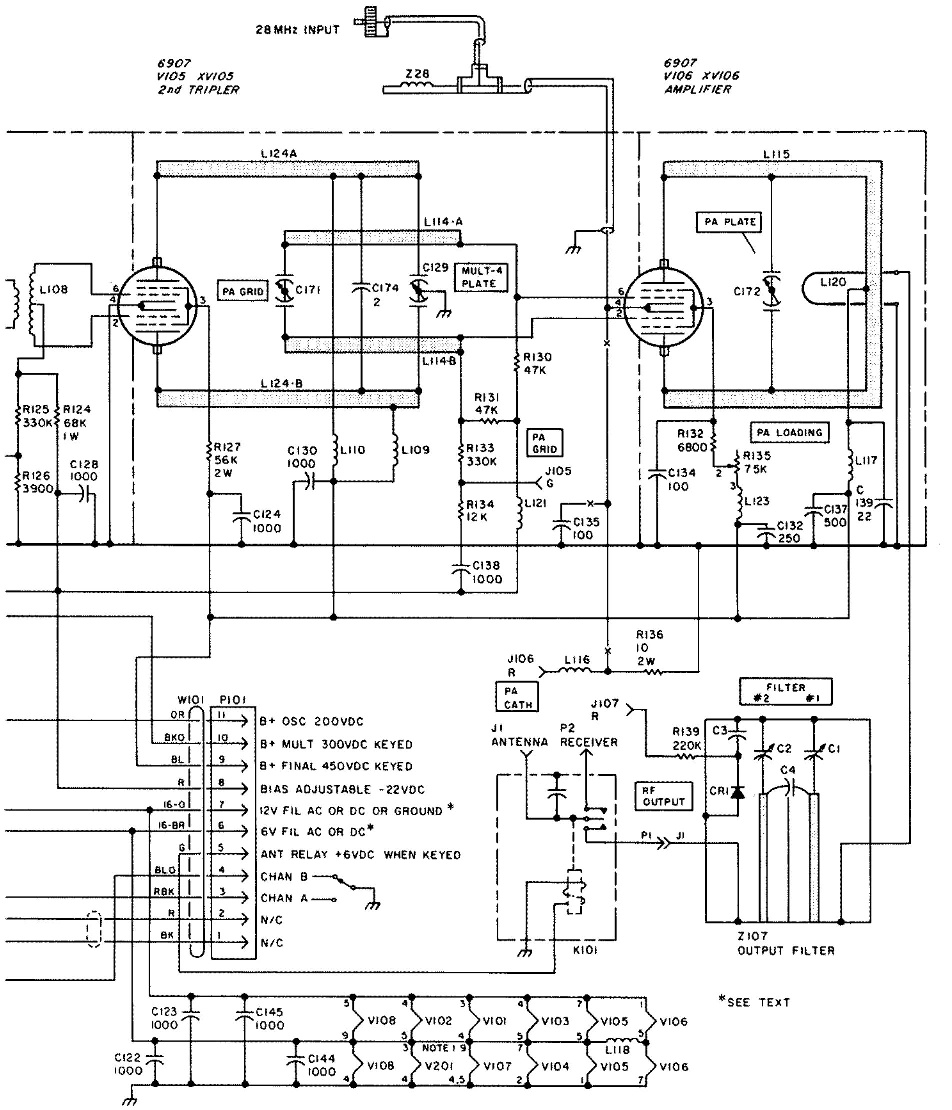

Fig. 1. Schematic.

If you have a model A1 unit and want to modify it to be an A11-type unit so you can switch between 432 and 435 MHz at the flip of a switch, send me an SASE for a schematic.

Install a 10-Ohm, 2-Watt resistor in another PL-259. This will replace the PL-259 with the rf choke for the bias setting in the alignment procedure only.

Alignment

Replace the PL-259 with the rf choke in it with the PL-259 with the 10-Ohm resistor in it on the T-fitting. Connect a voltmeter (2.5-volt scale) to where the exciter should connect on the T-fitting. Turn on the power supply and, after a few minutes warm-up, turn on the B+ voltages. Adjust the bias supply until you just start to get a reading on the voltmeter. This indicates that the mixer tube is just starting to draw cathode current. Remove the B+ voltages and replace the PL-259 with the rf choke in it. Do not connect the exciter yet. Turn the variable resistor on the side of the cage to fully counterclockwise.

Caution: Do not key the transmitter for more than 30 seconds at a time during the entire alignment procedure.

Connect the negative lead of the voltmeter to the MULT-1 test point and the positive lead to ground. Key the B+ voltage and you should see a reading of about 1 volt. This shows the oscillator is working. Move the negative lead to the MULT-2 test point and adjust the two transformers between the 6U8 and 6CL6 tubes for maximum voltage on the voltmeter (approximately .75 volts).

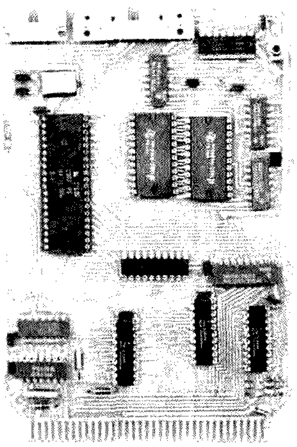
Move the negative lead to the MULT-3 test point and adjust the two transformers between the 6CL6 tube and the end of the transmitter strip for the maximum voltage (approximately 1.5 volts). Move the negative lead to the MULT-4 test point on the top of the cage next to the 2E26 tube. Using a nonconductive screwdriver, adjust C126, the 2E26 plate-tuning capacitor, for maximum voltage on the meter (approximately 2 volts).

Move the negative lead to the test point marked PA GRID. This is near where the new coax cable is coming out of the cage and the test point is green in color. Using a nonconductive screwdriver, adjust C129, the plate-tuning capacitor of the first 6907 tube, for maximum voltage by putting the screwdriver through the hole in the cage cover and down about an inch to engage the plate-tuning capacitor. This is a very sensitive adjustment. With the negative lead in the same place, adjust C171, the grid-tuning capacitor of the mixer tube, for maximum voltage on the meter. C171 is the capacitor right next to where the new coax cable comes out of the cage cover. You should repeak C129 again.

Connect a load to the output of the transmitter and connect the exciter to the coax T-fitting. You may want to connect a good UHF wattmeter between the transmitter and the load. I suggest a Bird wattmeter with a 25-Watt 200-500-MHz element. Connect the voltmeter with the negative lead going to ground and the positive lead going to the test point marked RF at the end of the cage area. Remember, do not key the transmitter for more than 30 seconds at a time in CW mode or you could burn out R132, a 6.8k ½-W resistor connected to the screen pin of the mixer tube.

Apply about 10 Watts of 28-MHz energy from your exciter and turn the B+ voltages on. Tune C172, the mixer-tube plate-tuning capacitor, for maximum voltage on the meter. Be sure you use a nonconductive screwdriver and place it down through

CONTROL
IN
BASIC



FOR $169.95

No Need For
-Assembly Language
-Development Station
-Expensive Test Gear

. . Just a Terminal

THE JARR Z8 BSC CONTROLLER

INCLUDES:
*Tiny Basic Monitor
*Timer/Event Counter
*4K User Eprom or Ram
*Over 200 Pages of Documentation
*RS-232 Serial Line
*14 Parallel I/O Lines
*Expandability!

FOR INTERFACING TO:
*Sensors *Displays *Keyboards *SCR's
*Triacs *Relays *Switches *A/D & D/A

APPLICATIONS:
*Heating Control
*Home Security
*Lighting Control
*Speech Synthesis
*Programmable Rotor Controller
*RTTY / CW Control
*Home Automation

With the Jarr Z8 Controller, 1000's of dedicated microprocessor control applications can be realized.

Development of a control program is easy!
By utilizing simple BASIC commands, create a program to accomplish your specific task. When your program does what you want, simply download from RAM to EPROM. From, then on, whenever the Z8 controller powers up it will automatically execute your control program.

JARR Z8 Controller Peripherals:
*Eprom Programmer/Cassette Interface (Model # Z8-ECI)
*24 Line Parallel I/O Card (Model # Z8-PIO)
*8 Channel Relay Control Card (Model # Z8-RCC)
*2 Channel Temperature Sensing Card (Model # Z8-TSC)
*Breadboard Interface Card (Model # Z8- BIC)
*Speech Synthesizer Card (Model # Z8-SSC)

Call, Write or Circle reader service number for detailed information on the **JARR** Z8 Control Family.

the hole in the cover of the cage to engage with C172. This is a very sensitive adjustment. Adjust the two controls on the output filter at the end of the cage area, by the antenna relay, for maximum voltage on the voltmeter or maximum output on the wattmeter. Go back and readjust C172 again for maximum output. I suggest that you take the output power right from the filter output connector without going through the antenna relay. You should go back and adjust C171 (PA GRID) again for maximum output.

Turn R135, the variable resistor on the side of the cage, fully clockwise again. Increase the 28-MHz input power up to 20 to 25 Watts and you should get between 8 and 12 Watts out of the mixer at 435 MHz. This completes the alignment procedure.

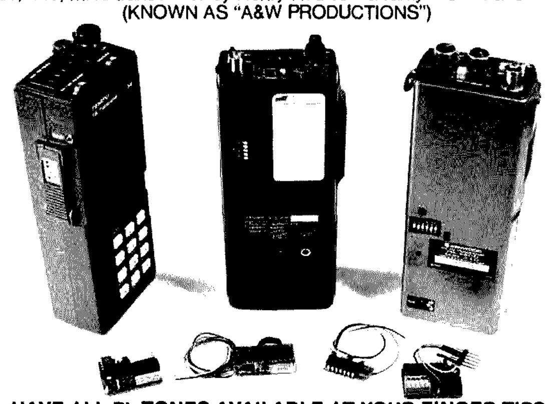
Operation

You may connect the mixer directly to the antenna or run the output of the mixer into an amplifier. I have used this mixer on 432 MHz with a 4CX250B amplifier to win many ARRL VHF contests in the Pacific Division. I have also used its predecessor, the A2 version of the transmitter strip, to make over 500 contacts on OSCAR 7, mode B.

As you can see, this is an inexpensive way to get a 435-MHz SSB signal on the air to input OSCAR Phase III. If you would like to use this same unit on 432 SSB, substitute a crystal with a frequency of 11.2222 MHz and follow the same alignment procedure as before. I hope this article will help many more stations get on OSCAR that would not have because of the high cost of new equipment. ■

AT LAST!

This service will be available nationally. Lab tested & time proven modifications professionally installed in your amateur Handy-Talkie 2M, 220, 440, MH2 transceiver by Henry Radios warranty technicians (KNOWN AS "A&W PRODUCTIONS")



HAVE ALL PL TONES AVAILABLE AT YOUR FINGER TIPS

Outboard the dip switch! Have it neatly inlayed into the back cover of your Handy-Talkie making all 32 PL Tones Selectable at a moment's notice.

$25 Got your own PL? Send it to us with your Handy-Talkie unit and we do the professional installation for you.

$55 We will install a new PL and inlay the dip switch into the back cover of your Handy-Talkie ready to operate.

Send us your Handy-Talkie unit and a check or money order plus $3.50 for shipping and handling payable to **A&W PRODUCTIONS, INC.**

For **TEMPO** units the dip switch is inlayed into the Push-to-Talk bar. The **TEMPO S-15** will have the dip switch inlayed into the back cover.

$45 We will install a **NEW BATTERY BEATER** in your **TEMPO S-1, S-2, S-4, S-5 READY** to operate. Your New Battery Beater will use the same jack as the charger with no new holes and regulation circuits built into unit. Comes with Cigar Lighter Adapter with internal fuse.

CONTACT A&W PRODUCTIONS FOR SPECIAL MODIFICATIONS YOU MAY WANT TO HAVE DONE. WE SPECIALIZE IN THE TEMPO HANDY-TALKIES.

WE ARE AN OFFICIAL "TEMPO" REPAIR STATION
ALL WORK GUARANTEED FOR 30 DAYS. SEND YOUR HANDY-TALKIE AND A CHECK OR MONEY ORDER TO:

Up and Coming: Direct-Broadcast Satellites

Part II looks at the technical problems with communications at 12 GHz, which may be offset by the advantages.

Timothy Daniel N8RK
7 Peabody Drive
Oxford OH 45056

Hams love a challenge. Why else would they erect 200-foot towers, endure cold mountaintops, or spend hours designing and building the ultimate receiver? The current generation of satellite television was a natural attraction for hams. Dedicated to doing more with less, electronics hobbyists took on the TVRO challenge and ended up creating a new home-entertainment industry.

Will the 1980s version of spacecasting, Direct-Broadcast Satellites (DBS), offer the same kind of opportunity that beckoned TVRO pioneers like W5KHT, W6HD, K4AWB, and N6TX? The first part of this article, in last month's *73*, concluded that DBS holds a different kind of promise. The presence of large, technically-advanced companies is likely to discourage garage-style entrepreneurs. But what about the basement tinkerer? For him, DBS could be a challenge par excellence.

This is not a "how to" article. With DBS service planned to begin in the mid to late 1980s, it would be premature to start manufacturing circuit boards. But if you have already mastered the reception of present-day 4-GHz satellite signals, then consider taking on the challenge of receiving 12-GHz signals from one of the "communications" satellites already in orbit or soon to be launched. Though no hobbyist has publicly announced such an accomplishment, an examination of the technical parameters will show that it is doable.

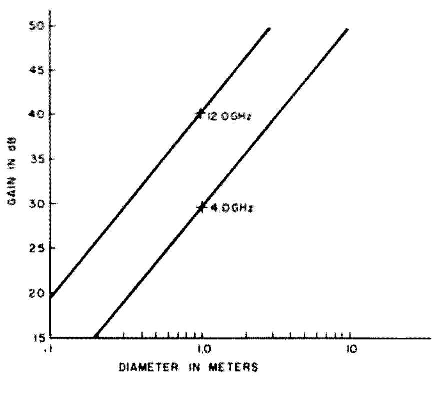

Fig. 1. The gain of a dish antenna depends on the frequency of operation and its efficiency. A one-meter dish has 10 dB more gain at 12 GHz than it has at 4 GHz, provided efficiency remains the same.

Why 12 GHz?

The choice of 12 GHz for DBS is not as baffling as it may first appear. Perhaps the most important reason behind 12 GHz is the need for small, inexpensive receive antennas. Fig. 1 shows that a dish, one meter in diameter, has roughly 30 dB of gain at 4 GHz, making it far too small for catching satellite TV signals on that band. The same dish has about 40 dB of gain at 12 GHz. A dish antenna's gain at a particular frequency is proportional to the reciprocal of the wavelength squared, hence the increase of 10 dB.

A second argument for 12 GHz centers on the ability to use larger bandwidths. DBS proponents have suggested using signals with bandwidths as wide as 400 MHz. The tenfold increase over 4-GHz signal bandwidths holds some exciting possibilities. We might be treated to high resolution video and have our choice of several different audio channels!

The technical attractions of the 12-GHz Ku-band are accompanied by some substantial drawbacks. While much of the theory that works at 4 GHz holds true at 12 GHz, actual Ku-band components require another magnitude of precision. Consider that a Ku-band signal has a freespace wavelength that is less than one inch long. At these frequencies, hardline gives way to waveguide and suitable microwave transistors, when available, cost in the hundreds rather than the tens of dollars.

The Satellites

DBS planners have laid the groundwork for a multi-satellite network. Depending on the proposal, there will be either three or four geosynchronous spacecraft, each one beaming to a separate region of the US. The multi-satellite approach offers two advantages over

the current system of using a single satellite to blanket the country.

First, by concentrating the satellite's signal on a smaller area, the cost and complexity of receivers can be lessened. When the antenna-size limitation, receiver-noise performance, and the substantial path loss (approximately 205 dB) are weighed against the need for snow-free pictures, it becomes clear that the new satellites must have an effective radiated power far greater than the 30- to 35-dBW signals emanating from the 4-GHz satellite-TV birds. Ku-band DBS signals will probably exceed 50 dBW and may even approach 65 dBW. A satellite capable of covering the continental US with that kind of signal would need close to 1000 Watts of output power, severely taxing the weight and power-supply limitations for spacecraft.

How do spacecasting transmitters generate high-powered microwave signals? The answer is, very carefully. Traveling-wave tube amplifiers (TWTAs) are used, often in groups of two or more since the largest single unit can generate no more than a couple of hundred Watts. TWTAs, like amplifiers for ham radio, can fail at the worst time. The world's first direct-broadcast satellite, a Japanese experimental spacecraft, had a shortened life due to TWTA problems. The push is now on to build higher power TWTAs and improve satellite power generation and cooling systems.

A second drawback to the single-satellite approach stems from biannual eclipses where the Earth prevents the sun's rays from reaching a satellite's solar cells. The satellite must cease transmitting or rely on heavy and expensive storage batteries. Rejecting the second alternative, it may be possible to place the satellite in an orbital location that causes the blackout to occur at an hour when few people expect television service. But, as Harley Radin pointed out in the August, 1982, issue of *Satellite Communications*, such a location would be over the Pacific Ocean and impractical for east coast reception.

With the single-satellite approach presenting problems at every turn, planners have suggested a multi-satellite system where each craft would serve either one-fourth or one-third of the continental US. In arguing for the three-satellite approach, Radin questions the need to match program times with the national time zones, a feature of the four-bird proposal. Instead, he suggests that using only three satellites will reduce the overall cost (satellites are expected to cost in the $100-million range) and make better use of the frequency spectrum and orbital space.

Should DBS become a money-maker, two additional problems may develop. First, there is a limited number of ways to launch a satellite. Companies that counted on the European Space Agency's Ariane launcher are beginning to have second thoughts, and the best alternative, the US Space Shuttle, is almost completely booked through the mid-1980s.

If a large number of satellites do end up in orbit, it could present problems on the receiving end. Dish antennas are limited to a very narrow beamwidth—about 3 degrees—and may need to be rotated to receive signals from different satellites. If motorized antennas prove too costly, an electronically-steered "flat" array could be introduced.

Receiver Performance

The plight of satellite-receiver designers is best expressed by the old saying, "He robs Peter to pay Paul."

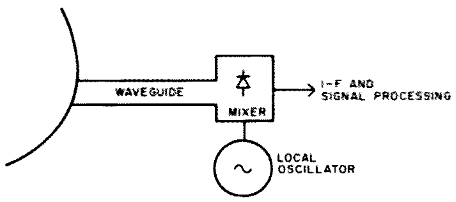

Fig. 2. The NHK Corporation of Japan receiver, described in the January/February, 1982, issue of High Technology, *uses direct conversion for low cost and a reasonably good noise figure.*

The tradeoff is between receiver-noise performance and antenna size. It boils down to getting acceptable performance at a reasonable cost. Acceptable performance is usually equated with a carrier-to-noise ratio (C/N) of at least 10 dB. While 10-dB C/N may not be studio quality, it does ensure reasonably snow- or sparklie-free pictures. DBS backers realize that their signals must compete favorably with conventional broadcasting and cable TV if they are to stand a ghost of a chance.

For an in-depth look at the "rob Peter, pay Paul" dilemma, read Stephen Gibson's "How Big a Dish?" in the November, 1981, *73*. The culprit, as Gibson points out, is noise.

In his article, "Direct Satellite TV: The 12-GHz Challenge" (*High Technology, January/February, 1982*), James Fawcette outlined three approaches to building receivers. The first and perhaps most startling method (shown in Fig. 2) is direct conversion, developed by the Japanese broadcasting giant, NHK. Akin to the simplest of ham receivers, the NHK design features a very low manufacturing cost. The signal goes from the antenna to a diode mixer via waveguide. There is no low-noise preamplifier stage. Fawcette cites an NHK claim of a 3.4-dB noise figure and 300-MHz bandwidth!

A more traditional approach to receiver design centers on a low-noise preamplifier circuit operating at 12 GHz. Like the current 4-GHz gear, several gallium arsenide (GaAs) field-effect transistors (FETs) are chosen because of their minimal noise contribution to form a preamplifier before the mixer stage. GaAsFETs are, however, expensive and difficult to use. Designers must pay close attention to the transition from waveguide to printed circuitry and use isolators to insulate the FETs from high swr. These additions can add to the receiver noise level and require a lot of individualized alignment. The result, while expensive, should be better than that which is achieved with the direct-conversion approach.

Hobbyists who want to roll their own 12-GHz low-noise amplifier might want to consider the Mitsubishi MGF-1403. This GaAsFET, offered by at least one *73* advertiser, has a Ku-band noise figure of less than 2 dB. If your pocketbook permits, you might want to try for an even better noise figure.

Manufacturers hope to avoid the cost of discrete GaAsFET front ends by fabricating GaAs integrated circuits. It is conceivable that the entire receiver could be on one chip. But until GaAs technology is refined and yield levels are boosted, receivers probably will employ hybrid circuitry using discrete front ends and integrated circuits for intermediate frequencies and signal processing. Siemans A.G., a European

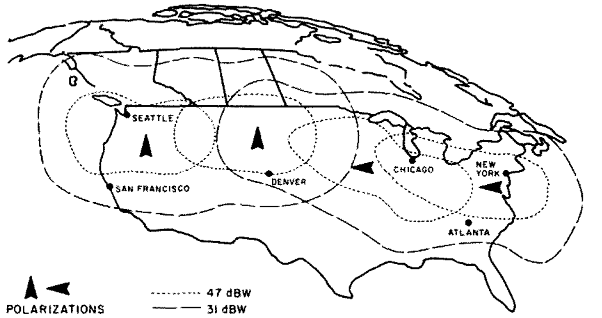

Fig. 3. ANIK C3, a Canadian satellite, may be the first source of North American 12-GHz television broadcasting. Its footprint will favor the northern United States. (Illustration from Satellite Communications, *July, 1982.)*

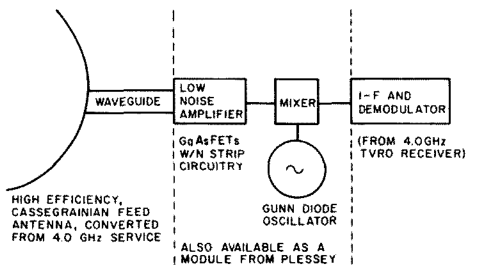

Fig. 4. By using a 4-GHz TVRO dish, front-end module from Plessey Corp. and integrated circuits for the i-f and signal-processing stages, a 12-GHz receiver could be within the reach of many hobbyists. For dyed-in-the-wool do-it-yourselfers, there are suitable GaAsFETs for building a 12-GHz low-noise amplifier, and a Gunn-diode oscillator could be used with a passive mixer for the downconverter stage.

corporation, already has introduced GaAs ICs that would follow the mixer stage in a DBS receiver.

A number of companies have finished prototype receivers and are laying the groundwork for manufacturing them in 100,000 quantity levels. European and Japanese companies like Plessey, Philips, Sony, NHK, and Siemans seem to be in the forefront. The late entry by American firms may be due to the lengthy FCC-approval process and lack of 12-GHz satellites for testing. Just who will dominate the US market remains to be seen. The ability to keep costs to a minimum could be the deciding factor.

Getting Started

If you have read this far and like a challenge, then consider getting in on the ground floor. In late 1980 a satellite built by Hughes Aircraft was put in a geosynchronous orbit of 106 degrees west. Operated by Satellite Business Systems (SBS), the spacecraft has ten-Ku-band transponders and is used by large corporations for high-speed data communication.

The all digital-time division multiple-access data format will make it difficult for hobbyists to receive any meaningful data from the SBS signals, but what the satellite does offer is a steady source for testing antennas and receivers. The transmitter footprint is said to be in the 43-dBW range, favoring the east central and western United States. SBS recommends that users have a 5.5- or 7.5-meter dish.

The first North American satellite to carry 12-GHz video on a regular basis will probably be ANIK C3, which was launched from the Space Shuttle last November. (See Fig. 3.) Built by Hughes Aircraft for Telesat Canada, ANIK C3 has 16 12-GHz transponders that can accommodate data traffic or two FM TV channels each. Telesat Canada plans to lease most of the transponder space to US companies, including several interested in experimenting with direct broadcasting. Although ANIK C3 transmissions aren't as strong as future DBS signals, they should be easier to receive than those from the SBS satellite, especially if you live in the northern US.

Finding suitable 12-GHz hardware will be the biggest problem facing pioneer tinkerers. One logical starting point is the dish antennas for 4-GHz TVRO reception. Some manufacturers even claim that their antenna will work just as well at the higher frequency. Whether you build or buy, remember that any dish antenna's performance is severely degraded if flaws in the surface accuracy exceed .1 times the wavelength of operation. For 12-GHz work, this means a tolerance of less than a tenth of an inch!

When choosing an antenna, pay close attention to the feed since it plays a big role in determining an antenna's efficiency. Remember, the feedhorn designed for a 4-GHz satellite system is *not* what is best for 12-GHz experimentation.

Choosing receiver components could be tough. If you have the necessary experience and test gear, you can roll your own 12-GHz LNA. Otherwise, you'll have to scour the surplus markets or save up enough money for a commercial-grade unit. Engineering evaluation models are starting to become available; Plessey Corp., for example, offers a complete receiver front-end module.

Hams who have experimented with Gunn-diode-based oscillators may want to try building their own local oscillator and diode mixer. The secret seems to be keeping the local oscillator's frequency stable and reducing unwanted sideband noise. Once you have perfected the preamplifier, local oscillator, and mixer stages, you can rely on proven intermediate-frequency and signal-processing designs. Fig. 4 shows one possible approach at assembling a working 12-GHz terminal.

Does all this sound like too much—an impossible feat? Then think about the not-so-distant past when Bob Coleman K4AWB built a 4-GHz satellite terminal using a few hundred dollars worth of surplus "junk" and a VTVM. For him, satellite TV was an opportunity rather than a roadblock and there was no need to wait for someone else to lead the way.

Who will be the first to master the 12-GHz DBS challenge?

Author's Note

Since the legality of unauthorized reception of satellite signals has not been decided, readers are urged to use discretion in decoding or disseminating any information they might receive. ■

The Fun-Vac: A Synthesis of Old and New

This one-tube transmitter combines the circuits of the fifties with the technology of the eighties. It also keeps your coffee warm.

Ed. Note: PC boards for this project are available from the author for $7.00 ppd.

The response to my series of articles on Fun home-brew gear has indicated that there is a diverse group of people building gear today. Without question, the one central and overwhelming theme of the response has been about *simplicity*!

The emphasis in home-brew products has changed dramatically over the years. Nearly everyone has as his main rig a factory-built transceiver which is good on today's crowded bands. However, the lure of home-built gear seems to entice even more hams than before, quite possibly because they are building for fun and challenge and not because of necessity or lower cost.

The "Fun-Vac," the 2-to-5-Watt 40-meter CW transmitter described here, is in response to requests from both old-timers and newcomers for a different kind of transmitter—a *tube* transmitter. Believe it or not, I did say *tube* (hence the "Vac" for vacuum). What a challenge it was to design and build a tube transmitter based on the Fun-gear principles of no adjustments and all parts coming from Radio Shack! It really *was* fun to return to the early days of my ham career (mid-sixties) and work with vacuum tubes. However, modern construction practices and the 1980s philosophy of home-brew gear were used in designing this very simple, very reliable, one-tube, 40-meter transmitter.

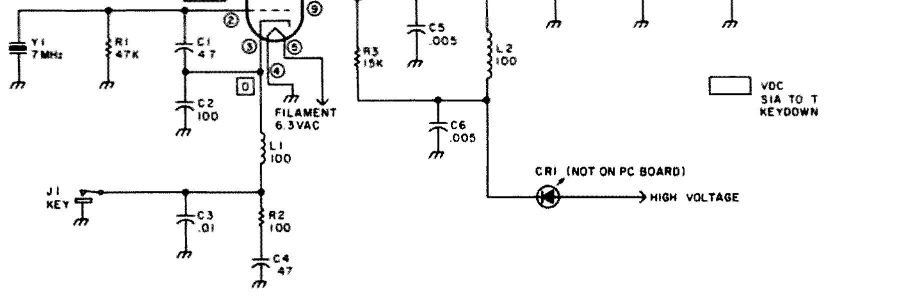

Fig. 1. Fun-Vac schematic.

Why use a tube?

First, it is nostalgic for the many who entered the ham-radio field before the seventies.

Second, many older hams have stopped building due to the extinction of tube circuits. This project hopefully will bridge the gap for them between current transistorized gear and the older, massive, point-to-point construction-type tube rigs which required hours and hours of wiring, sheet-metal work, and critical adjustments.

Third, many new hams have virtually no experience or education regarding tubes, and a simple one-tube project is a good way of discovering our tube heritage (which may help in understanding transistor circuits).

Fourth, it is just plain fun to integrate the fifties and sixties home-brew ideas with the home-brew philosophy of the eighties!

I firmly remain, however, a proponent of state-of-the-art gear. Transistors are much more efficient with their use of power, and 12 V

to 24 V is much, much safer to work with than 300 V!

Objectives

My main objective with this rig was to design a tube transmitter that fit in with the entire Fun series of simple, low-cost gear. It would be worthwhile to review the entire series, particularly the article on the Fun-Mitter (*73 Magazine,* February, 1981; see also "Fun-Equipment Revisited" in the January, 1983, issue). The Fun-Mitter is a 5-Watt, 80- through 15-meter solid-state transmitter. The characteristics of the Fun gear are: small size, simple construction, no adjustments, and all parts available from Radio Shack.

The objectives of the Fun-Vac were, in addition:

- PC board construction with the same size board as other Fun gear (2¼" × 3")
- a cost less than $25
- easy assembly
- 2 to 5 Watts output

All of these objectives were met. Even a 300-volt power-supply design is included here.

Circuit

The basis of the transmitter is a 6BQ5, a 9-pin miniature beam-power pentode available from Radio Shack. The 6BQ5 is a rugged device capable of dissipating 10 to 15 Watts under a 50% CW duty cycle.

The 6BQ5 functions as both oscillator and amplifier. The oscillator uses FT243 fundamental crystals in a Pierce configuration. C1 and C2 provide feedback between the control grid and cathode. The oscillator is keyed by breaking the cathode-to-ground connection. L1, R2, C3, and C4 comprise a wave-shaping circuit to eliminate clicks and sluggish starting of the oscillator.

The big power-waster of this circuit (as with all tube circuits) is the filament. A tube works by heating the cathode to jar electrons loose from its specially-coated surface. This is the function of the filament (or heater) which actually glows orange, warming the cathode. The 6BQ5 requires 6.3 V at .75 Amps applied to the filament. (This is about 4½ Watts, or as much as the total output power of the tube!)

The plate operating voltage (250 to 300 V) is applied through plate choke L2. In order to meet the objective of using Radio Shack parts, L2 was required to be 100 uH. This is somewhat less inductance than the normal value of plate choke, but absolutely no problems were encountered. Rf output is taken from the plate through C7 and applied to the matching network, L3, L4, C8-C10. This network serves two purposes and is different from the norm in tube circuits.

Its first purpose is to match the impedance of the plate (about 2500Ω) to a 50Ω antenna load. This is accomplished by C8, C9, and L3. The second purpose is harmonic filtering, which is accomplished by both sections. The matching network is actually two pi networks combined. One matches 2500Ω to 50Ω and the other is a 50Ω-to-50Ω match.

Although the pi network is a standard method of matching impedances in a plate circuit, this network is different in one aspect: it is fixed-tuned. Normally, a variable-load capacitor would be used at C10 to adjust for an antenna load of between 30Ω and 70Ω. All of today's equipment is fixed-tuned for a 50Ω antenna load, and with antenna transmatches in abundance, the necessity for a variable load control no longer exists. Another norm in tube circuits is to use a variable-tune-control capacitor at C8. By designing for a somewhat lower Q, this capacitor was made fixed. No tuning adjustments are required! The entire transmitter can be built on a small PC board just like today's solid-state rigs, with no bulky front-panel variable capacitors!

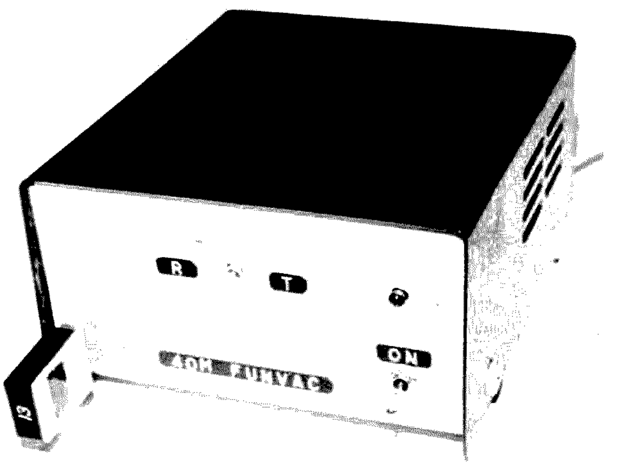

Photo A. Front view of the Fun-Vac.

The matching inductors, L3 and L4, are made from Radio Shack 10-uH chokes as has been done with all previous Fun gear. By removing the required amount of turns, the needed inductance is easily obtained. These chokes make for small and easy-to-make inductors—again, something quite unusual in a tube circuit.

The LED, CR1, was included to provide a method of monitoring plate current. The LED is wired in series with the plate voltage and lights brightly when the plate current passes through it. Because of the very low voltage drop across the LED, no power is lost in it. (It also is fun to use a modern solid-state device to monitor current in a tube rig!)

Power-Supply Circuit

The Fun-Vac operates from two power-supply voltages, 6.3 volts ac and approximately 300 volts dc. The 6.3-V-ac filament voltage is somewhat critical in value, but the high voltage can vary between 200 and 350 volts. These voltages can be obtained from an existing supply or a supply can easily be built and incorporated into the same box with the Fun-Vac PC board. I chose to include power supply and Fun-Vac in one box, as shown in Photo B. However, the voltages can easily be "stolen" from a tube-transceiver supply or a similar supply by using the appropriate connector on the Fun-Vac chassis.

A simple circuit to obtain the needed voltages is shown in Fig. 2. An attempt was made to design a supply that also met the Fun gear objective of obtaining all parts from Radio Shack. The design shown meets that objective although it represents a rather unorthodox approach. By using two step-down transformers

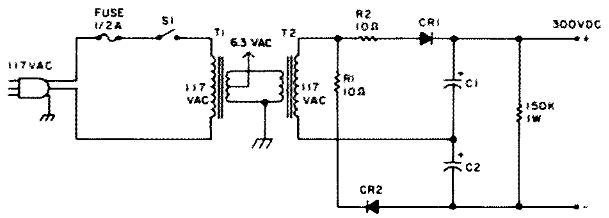

Fig. 2. Fun-Vac power-supply schematic.

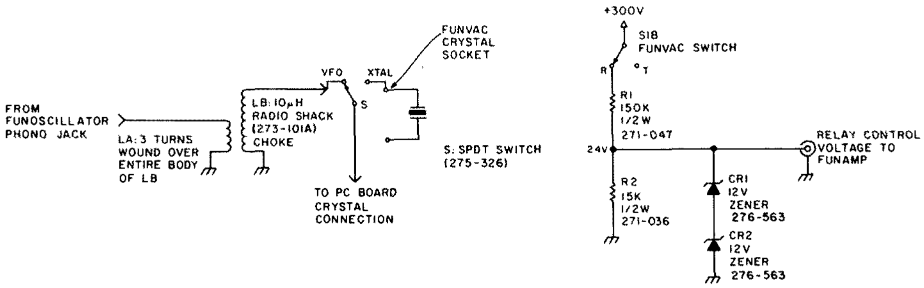

Fig. 3. Using the Fun-Oscillator and Fun-Amp with the Fun-Vac. The Fun-Amp relay-control voltage is needed due to the methods used with the Fun-Mitter. Mount resistors R1 and R2 very close to S1.

back to back, a secondary ac voltage of 117 volts is obtained. This is possible because of the relationship of the turns ratio of the transformer. (It is an old trick, used in the past to obtain a negative bias voltage for tube rigs.) The 117 volts ac is applied to a full-wave voltage doubler which provides 2.8 times the rms voltage (2.8 × 117) to provide about 320 volts dc.

This arrangement is not extremely efficient and the parts shown do not provide a very "stiff" high-voltage supply. This results in less power output than the tube is actually capable of, but the parts are easy to obtain and the circuit is easy to build. The transformer windings must be connected in phase in order to add voltages. If, after the supply is wired, no ac output occurs at T2 secondary, then reverse the connections at T1 secondary.

Using the Radio Shack parts shown does make the power-supply portion of the Fun-Vac nearly as expensive as the rf circuitry. It may be possible to substitute for the filter capacitors by using the junk box or buying from a local TV repair shop. A value of 50 to 100 uF will work fine, and even less capacitance can be used at the expense of less filtering and regulation. Also, the transformers can be replaced by any transformer that can supply the needed voltages.

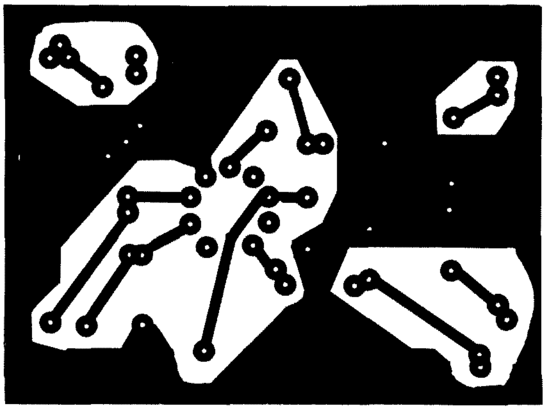

Fig. 4. PC board.

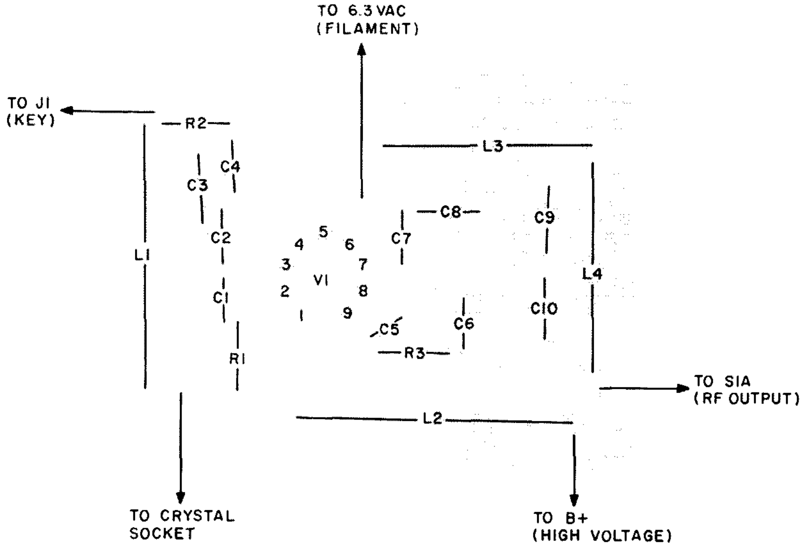

Fig. 5. Component layout.

Construction

Before beginning the actual construction of the Fun-Vac, a review of safety practices with high voltages is necessary. *The high voltage used in this circuit can be lethal!* When voltage is applied, never touch anything on the PC board or in the box. Always keep one hand away when making any measurements.

Using PC board construction for the Fun-Vac greatly simplifies building the rig and makes it as simple to build as solid-state gear. PC board use also eliminates wiring errors. All of the parts except the jacks, switches, and the plate-current LED are mounted on the board.

The 6BQ5 tube can be soldered directly to the PC board without a tube socket. This makes the loaded board shorter, which is important in mounting. If you purchase a new 6BQ5 from Radio Shack, there should not be a need to replace the tube, rendering the usual practice of using a tube socket unnecessary.

FT243 crystals and sockets can be obtained from a number of sources and are quite inexpensive. Mount the socket on the front panel to facilitate easy changing during operation.

The plate-current LED should be mounted in a hole on the front panel and glued in place. Route the wires to the LED carefully since these wires carry the high voltage. If possible, don't leave bare wire exposed anywhere in the high-voltage circuit.

The sheet-metal work necessary with the Fun-Vac is much simpler than it was in a comparable tube transmitter from fifteen years ago. Before, heavy metal was used, often even steel, and it had to be punched for tube sockets, variable capacitors, and large coils. Using the Radio Shack cabinet makes sheet-metal work easy. The light-gauge alumi-

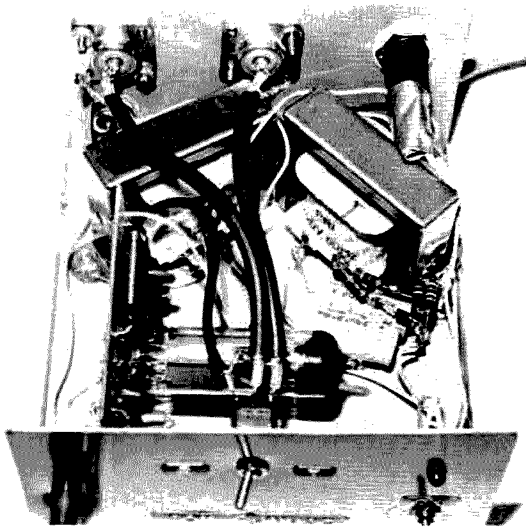

Photo B. Inside view of the Fun-Vac.

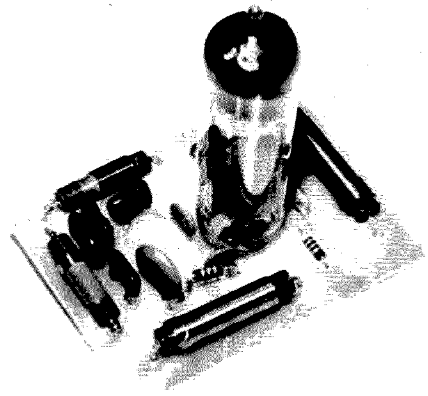

Photo C. PC board for the Fun-Vac.

num is easily worked using a hand drill and a knife.

Mounting of the PC board in the cabinet should be done with care. If the Radio Shack cabinet is used, it will be necessary to mount the board at right angles to the case, as shown in Photo B. If desired, the bottom of the board can be covered with electrician's tape to keep fingers from accidentally touching the high voltage.

The wiring used is not particularly critical. The filament wire should be at least 22 gauge. All rf wiring should be with coax, and RG-58 will work fine.

After the power-supply section is completed, do not connect the voltages to the Fun-Vac PC board. This will be done after proper operation of the supply is verified.

Vfo and Amplifier Use

The Fun-Vfo (2/82) and Fun-Amp (5/82) can be used with the Fun-Vac easily. Using the Fun-Vfo requires the addition of a step-up transformer to match the output impedance of the Fun-Vfo to the high impedance of the control grid of the Fun-Vac. The vfo signal is applied to the crystal socket. A switch can be used to switch between vfo and crystal. Details of the impedance transformer and possible switching arrangement are shown in Fig. 3.

The Fun-Amp is easily added to the Fun-Vac. It requires a control signal to control the Fun-Amp relay; this can be brought out of the Fun-Vac through a phono jack. The Fun-Amp will provide around 20 Watts of output power from the Fun-Vac. Details of the Fun-Amp use are given in Fig. 3.

Adjustment

The safety factor cannot be overemphasized. During adjustment, with the case open, it is very easy to accidentally touch the high voltage. Whenever the cover is off, always be aware of where the high-potential voltage points are.

The only adjustments of the Fun-Vac are really not adjustments at all; they are checks to ensure proper operation. If possible, obtain a voltmeter capable of measuring ac and dc voltage of greater than 300 V. At this time the two power-supply voltages should not be hooked up to the Fun-Vac. With the power on, carefully measure the high voltage. The reading should be between +250 volts and +350 volts.

Next, connect the filament-voltage wire to the PC board. Switch the voltmeter to the ac range and measure the filament voltage. It should be around 6.3 V. If it reads more than 7 volts ac, a filament-voltage dropping resistor may need to be added—$R = (V - 6.3)/.75$. At this time, with 6.3 V ac on the filament, there should be an orange glow from the tube, indicating that the tube filament is working.

Next, with power off, connect the high voltage to the circuit board through the front-panel plate-current LED. Also, hook up a dummy load to the antenna connector and insert a key into J1.

Turn the power switch on and wait at least 30 seconds for the filament to warm up.

	Line cord	278-1255

With a 40-meter crystal installed and the receive/transmit switch set to transmit, close the key. The front-panel plate-current LED should light, indicating the plate current of around 30 to 50 mA. This indicates proper operation. If a wattmeter is connected between the antenna jack and the dummy load, a power output of between 2 and 5 Watts should be observed, with the key closed.

For vfo operation, merely substitute the Fun-Oscillator for the FT243 crystal and proceed as above.

If problems are encountered, a logical analysis should reveal the trouble. If power-supply voltages are correct, then the problem can be isolated to the Fun-Vac PC board. Measure the voltages at the various points around the board corresponding to the indicated voltages on the schematic. If your voltages vary significantly from those given, then check and re-check for improperly soldered connections, miswiring, or faulty components.

Operation

Using the Fun-Vac for contacts is almost as much fun as building it! As with the Fun-Mitter, a 50Ω resonant antenna must be used. This usually will provide an swr of 1 to 1, which is a good method of monitoring load conditions. With today's stations, the necessary 50Ω-load antenna probably already exists due to the prevalent use of transmatches.

Allow the Fun-Vac to warm up for at least 30 seconds before use. In some ways, the soft warm glow of the tube as you operate is a reassuring feeling—reminiscent of days gone by. Incidentally, the heat generated by the soft, warm glow of the tube literally will keep your coffee warm—a side benefit of the Fun-Vac.

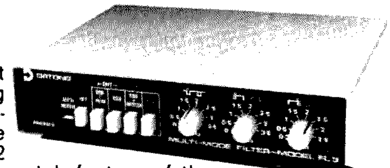
To operate, merely select the correct operating frequency, switch S1 to transmit, and begin keying. The receiver is connected to the receive antenna jack on the rear panel of the Fun-Vac. The low power of the Fun-Vac eliminates the necessity of a sidetone or receiver mute control since the actual signal can be listened to on the receiver without overloading.

Conclusion

The Fun-Vac provides a means of experimenting with tubes using modern methods. (If other band coverage is desired, refer to the Fun-Mitter articles.) It's amazing how simple those massive old rigs can be. Happy nostalgia! ■

GET COMPETITIVE...GET DATONG!
World's finest accessories for the serious operator

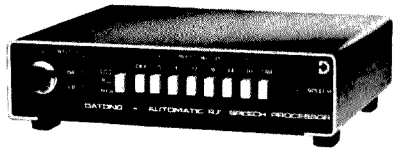
FL-3 = FL-2 + AUTO-NOTCH



That's right! What you have been asking for is here. Combining the knife-edge selectivity of the FL-2 with the unique auto-notch feature of the FL-1 has produced our most effective multi-mode audio filter ever. Double-notch capability (one manual and one auto) for when that second whistle appears.

$284.95

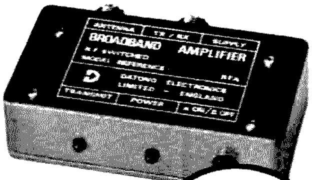
ASP — RF SPEECH PROCESSOR



Installs in MIC line. RF clipping with speech shaping from 0 to 30 db in 6 db steps. Frequency response 400-3400 Hz ± 3 dbs. Total harmonic distortion at 1 KHz, at 30 db clip level — 1/2%. Accepts Hi or Lo impedence MICs.

$179.95

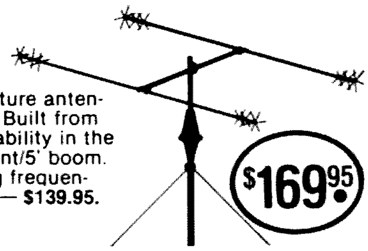
RFA—BROADBAND PREAMPLIFIER



Strengthens signal reception of any transceiver/receiver between 5 and 200 MHz. 9 db gain + low noise and 3rd order intercept of + 20 dbm. RF switched. Requires 12 dc @ 40 ma.

$74.95

"G4MH MINIBEAM ANTENNA"



High performance, miniature antenna has 6' turning radius. Built from quality materials for durability in the worst weather. 11' element/5' boom. Weighs 14 lbs. Operating frequencies: 20m, 15m, 10m. Kit — **$139.95.**

Adventure in Sarawak

Two DXpeditioners journey to the land of headhunters— and send a signal to the rest of the world.

Kirsti Jenkins-Smith VK9NL
PO Box 90
Norfolk Island
Australia 2899

The three 9M8s; left to right, Jim 9M8JS, Paul 9M8PW, and Kirsti 9M8NL.

Jim at the rig.

Sarawak—the land of the Hornbills, in Northwest Borneo: It is a country of rain forests, rivers, and unexplored areas. It is also a country of culture, arts, and handcrafts. Once the domain of headhunters, Sarawak is now the largest of Malaysia's 13 states.

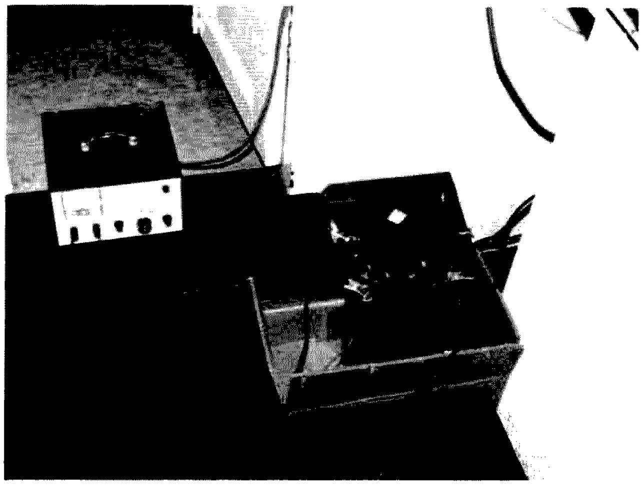
So reads the caption on our QSL card from this operation. The idea of visiting Sarawak during our holidays came to us early in the year. It did not seem to appear on any of the guided-tour brochures which came our way, and as we are not very tourist-minded, this made us look into the possibility of visiting and also doing some operating from there.

There were no problems regarding travel and visas. Modern jet-liners connect with Kuching daily, and for us it was a matter of traveling Norfolk Island—Sydney—Singapore—Kuching. We had contacted Paul 9M8PW beforehand and he was most helpful in arranging accommodations for us in the Anglican Church hostel. Here we were able to rent a small flat and thus be independent.

This is necessary in this sort of venture since not everyone appreciates their houseguests staying up through the night making cups of coffee and shouting into a mike. And hotel accommodations—apart from being expensive—present a problem in that hotel mealtimes do not coincide with the times of the day when band conditions are down to nothing and it is most suitable foı the operators to take a meal. In fact, they have a way of serving dinner and breakfast at peak operating times. So the hostel was ideal in many ways. It also was central and close to shops and restaurants.

We had applied for our licenses months before, and on arrival in Kuching were informed that these would be issued for the period of time we were visiting the country. This was good news indeed, as we were well aware of the reluctance to issue guest-licenses in Malaysia.

It now was a matter of proceeding to set up our operating quarters and station. Jim got busy with the multiband dipole which we eventually were able to hang from under the roof of the building across the yard and make fast in a suitable tree. Paul had a beam he was not using which he lent us. It needed some repairs and handiwork done to it, and Jim got busy with this chore. At the same time, we were making enquiries as to where we might be able to obtain a steel water pipe to mount the beam on. We were met with a strange re-



The battery setup after the lightning strike.

Our water-pipe antenna, overlooking Kuching.

luctance which we did not get to understand until over a week later, but we decided to find pipe for ourselves.

Nowhere did we see such an item, but after making our way through nooks and crannies in the shopping center, we finally found a shop where they said that they could help. So across the street we went; a large storage room was unlocked, and there within were literally hundreds of pipes. We selected a 20-foot piece and asked if it could be brought home to us.

"No, no (with an apologetic smile)!" Well, by this time we thought we had wasted enough time on the project, and the main thing was that we had the pipe within our reach. So resolutely we picked it up between us and paraded home through the streets to the vast enjoyment of the locals. Once home, there were no more difficulties. The caretaker and one of the gardeners came along, offered to help us put it up, and the job was done in minutes.

Later on, visiting the police museum at Fort Marguerita, we realized why we had experienced some reluctance in "operation water pipe." There on display were several guns and mortars homemade from water pipes which had been confiscated from terrorists. We hasten to say that Sarawak is a well-ordered and safe state at present, but obviously they have learned from history and are not taking any chances.

We were now in business. We had decided to concentrate on CW contacts as this mode was more needed from East Malaysia. We did not have a thundering success that first day. We had the dipole only up to the first floor and there was a CW contest on that weekend. So, unless people were looking for us, we could not break through on the busy bands. We also found that propagation was not the best to America and Europe, but was excellent to Asian countries and the Pacific. It took a couple of days to get the antennas erected to their full potential, but gradually we worked our way into the rest of the world.

Openings to America and Europe continued to be a bit tricky, but with cooperation from the people calling, we were able to work pileups giving such reports as 529 and even 429. This is not possible unless there is some restraint on behalf on the ones awaiting their turn. The bands usually opened properly for a few hours from midnight on and the path would be open to the USA and Europe, which created some tremendous pileups. The Europeans are not known for their patience and restraint in these circumstances, so it was plain hard work. It was, on the other hand, a pleasure to work a pileup of JA-boys. Their operating manner is above reproach.

Anyway, we continued in this manner for the first week and were looking forward to the weekend when lots of people who have only weekends available for their hobby would be around. On Saturday afternoon, however, there was a tremendous flash of lightning simultaneous with a deafening crash of thunder. Jim was outside making improvements to the antennas and was holding the 40-meter dipole in his hand at the time. It was lucky that he escaped being sizzled. That the power supply to the rig died instantly is really of minor importance in comparison. However, we were effectively shut down for 24 hours while we tried to repair the power supply.

We were able to buy some of the components we knew had blown, but after struggling until 2:00 am Sunday replacing these and still not making it work, we realized we were going nowhere unless we could gain access to a good ham shop. With one resident ham in the country, the shops did not stock ham gear. We finally arranged to hire a battery and charger which gave us 25 Watts, and by borrowing Paul's linear, we could bring this up to 100-150 Watts and continue operation.

The second week was mostly a continuation of the first week. The number of QSOs crept upwards, and it was nice to meet old friends in the pileups. We had realized by now that checking into nets we usually checked into from Norfolk Island was virtually impossible due to lack of propagation at those specific times. So, we carried on with the pileups, still concentrating on CW, Jim with his fancy electronic keyer and I with my old faithful straight key. (I want to go down in history as the only DXpeditioner stubbornly sticking to a 1940-model straight key in 1982, hi.)

We had by now been in Sarawak long enough to have spent time sightseeing and getting the feel of the place. Kuching is a fascinating city with all its old-world charm intact. There are the old narrow streets lined with shops absolutely spilling goods of every description out onto the footpaths. There were the handmade souvenirs made from local materials, and there were

The author stayed at the rig when the aerial fogging to kill mosquitoes began.

A typical shop in Kuching.

the friendly people, hardworking and cheerful. We spent many hours in the museum, learning a lot about the culture and history of the country.

And not far out of town was the jungle, practically undisturbed. We also were aware now that the dreaded dengue fever was around. We swallowed anti-malaria tablets against malaria and kept our fingers crossed against cholera, but as far as dengue was concerned, we just did our best to keep the mosquitos at bay by spraying the rooms and burning mosquito-coils through the night. We still became covered with bites and just hoped it was not the dengue-carrying kind of mosquito that had feasted on us.

The authorities had an ongoing eradication scheme against this particular beast, and one rule was that if someone contracted dengue, every house in the neighborhood was treated with a sort of spray. So it was that on one fine evening there was a whirring sort of noise outside, and the next thing we knew the flat started filling up with a dense fog. (See photo of the author at the rig at the beginning of the fogging process.)

It got so thick that we could not see at all at a distance of 2-3 meters. We could not breathe, either, so we agreed there was a limit to how devoted one can be, hi, and we would not be much use to our fellow amateurs if we suffocated. There was also the fact that we did not know exactly what the fog contained and just how harmful it might be to humans. So it was a matter of QRT and escape downtown for a meal. (The frogs were particularly noisy that night. We think they were kicking up a row because their favorite food had been done away with!)

All things come to an end, and so also did our stay in Kuching. We had settled in properly and were most reluctant to leave. We took one last look out the window at the view of tile-covered roofs, charcoal smoke rising amongst them, and one last admiring look at the orchids growing in a hedge along the footpath. Then a quick good-bye and *au revoir* to Paul's family and Paul drove us to the airport.

We really had not wanted to go, but we had received the good news that we had been successful in chartering a vessel, the *Cheynes II*, for our January, 1983, Heard Island DXpedition. So, although we had an unforgettable holiday and made 10,500 QSOs in Sarawak, we knew that loads of work regarding our Heard Island trip would be waiting for us at home and we just had to move on.

Afterthought: It was very hot in Kuching. There never seemed to be any breeze to relieve the heat of the day. And as the bands closed in the middle of the day, this was when we emerged outside for sightseeing and shopping. Strange how that old tune kept coming into my mind all the time: Mad dogs and Englishmen go out in the midday sun . . . It could just as well read: Mad dogs and ham-band-fans go out . . . etc.! ■

Put 2 Meters in Your Shirt Pocket

Radio Shack's Pocket Weatheradio makes a dandy 2-meter receiver. A few quick modifications will get it right on target.

Lester Kolb K3PJG
PO Box 161
Lebanon OR 97355

Quality, simplicity, and low price make this shirt-pocket two-meter receiver surpass anything on the market, if indeed such a compact gadget with these features is available.

The heart of the FM monitor is a "Pocket Weatheradio" which is listed in Radio Shack's 1982 catalog for $12.95 and measures less than 4 × 3 × 1¼ inches. Originally covering the 162.40-162.55-MHz weatherband, the state-of-the-art circuit features of the Weatheradio make it an ideal choice for conversion to two-meter FM. The frequency modification consists of simply adding three 5-pF capacitors across three inductors. This modification alone makes a dandy monitor, but the addition of a simple squelch circuit puts icing on the cake.

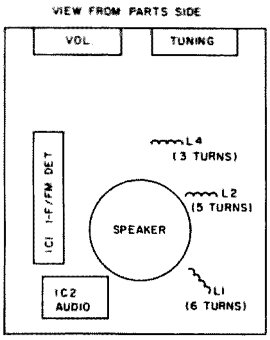


Fig. 1. Weatheradio component layout.

Weatheradio Circuit

The schematic included with the radio shows a simple, well-designed circuit consisting of a zener-regulated, three-transistor front end followed by a 4.5-MHz ceramic filter and a total of two ICs for i-f amp/FM detector and audio amp. The local oscillator is tuned by a varicap diode, and a 10k pot serves as a tuning control. The rf amp is not variably tuned since the small frequency range does not require it. Selectivity and frequency stability are excellent for a tunable VHF receiver, but don't expect top sensitivity.

Disassembly

Snap the plastic cover off the Weatheradio case. A cardboard insert over the circuit board is firmly glued to one of the electrolytic caps. Carefully remove this insert from the cap to have a look at the board. The cardboard insert can be cut off permanently except for the nine-volt-battery area. With a miniature phillips screwdriver, remove the two screws holding the volume and tuning knobs to their shafts. Also remove the two screws from the circuit board and the one anchoring the whip antenna. Remove the whip through the top of the case and take out the circuit board. Unsolder the leads from the speaker itself to avoid errors when reconnecting. Use small clip leads to the speaker while testing.

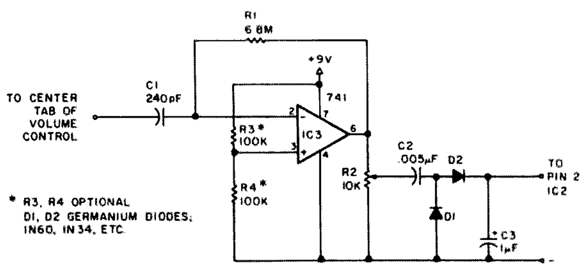

Fig. 2. Hybrid squelch circuit.

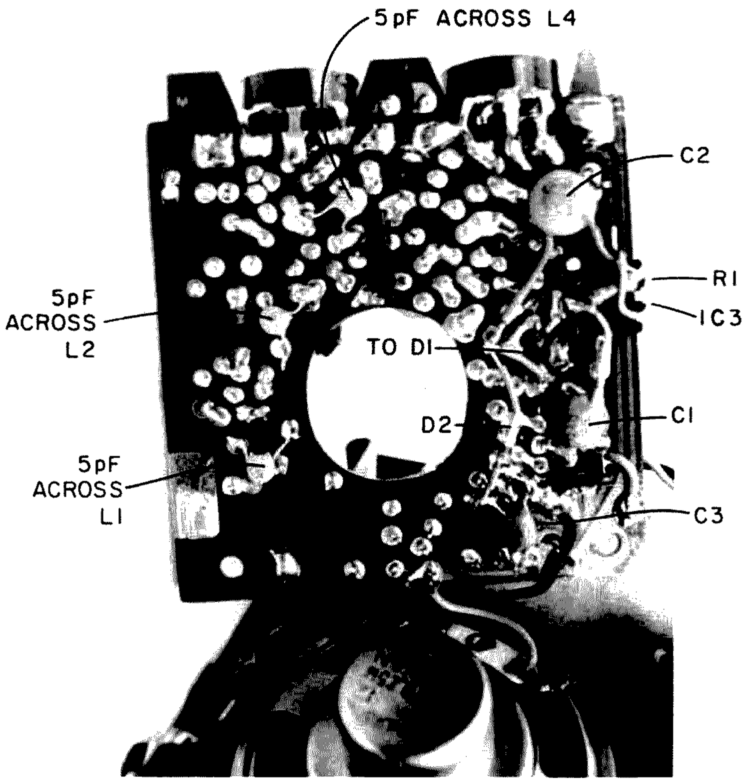
Frequency Modification

All that is required to cover two meters is the addition of a 5-pF capacitor (parallel) directly across inductors L1, L2, and L4. The locations of these coils are shown in Fig. 1. No existing parts are removed. After soldering these caps into place on the foil side of the board, reconnect the speaker, slip the board back into the case, and install the knobs and

whip for final testing. Reconnect the battery, set the tuning knob to mid-position, and with a toothpick or pointed nonmetallic tool, spread or compress L4 (local oscillator) until you hear a local repeater signal or desired center frequency from a signal generator. L2 and L1 (rf amp) should be spread or compressed in the same manner for maximum quieting, which can be accomplished only with a weak signal, preferably from a signal generator. Even though coupling between the local oscillator and the rf amp is very light, peaking of L2 for maximum sensitivity will shift the receive frequency slightly, so keep retuning onto frequency as L2 is being peaked; an increase in noise may be a shift off frequency rather than a decrease in sensitivity. Strong signals can be received even without adjustment of L2 and L1, but peaking (especially L2) is recommended for best sensitivity.



Circuit modifications.

Hybrid Squelch

Drilling holes or adding controls and switches to an otherwise attractive custom case is both difficult and unsightly. With this in mind, I came up with a novel idea which I call a hybrid squelch; the volume control doubles as a squelch control. The squelch engages at (and remains engaged above) any preset volume level suited to preference by varying the squelch sensitivity setting of R2 (Fig. 2). Once this R2 level is set, it needs no further adjustment. Although the most sensitive volume/squelch setting is just at threshold, a moderately strong signal will open squelch even if set at full volume. The use of the volume control as a squelch control is accomplished by coupling the input of the 741 op amp directly to the center tab of the Weatheradio volume control with a 240-pF capacitor. Thus, the input level to the noise amp/squelch switch varies with the volume setting.

Fig. 2 shows the complete squelch circuit. The 741 (DIP) op amp serves as a high-gain noise amplifier. Germanium diodes D1 and D2 provide a dc voltage which mutes the Weatheradio audio amp (IC2) at pin 2 when no signal is present. The 240-pF coupling capacitor helps eliminate passage of voice frequencies. However, if you find that, at high-volume settings, heavy modulation activates the sensitive squelch during voice peaks, reduce squelch sensitivity R2 until a compromise position is reached. To save space and eliminate the need for a subminiature pot, I adjusted R2 to the desired level, measured the resistance on each side, and substituted fixed resistors as a divider. An alternative would be to substitute a fixed 10k resistor for the R2 pot (connecting C2 to the junction of R2 and pin 6 of IC3) and to lower the gain of IC3 by reducing R1 to anywhere between 6.8 and 2.2 megohms. For this approach, I found the optimum value to be somewhere between 2.2 and 4.7 megohms. R3 and R4 on pin 3 of the 741 are standard practice, but optional; mine functions perfectly without them.

Construction Notes

Store all tiny screws and the knobs in a cup; they have a tendency to wander off. All parts for these modifications were soldered directly to the foil side of the Weatheradio board, each supported by its own leads or short lengths of thin but rigid wire. Space is limited, requiring ¼-Watt resistors and other parts of miniature variety. The 741 DIP was mounted against the foil side of the board, leads up, between IC1 and the immediate side edge of the board, with leads trimmed short. Keep parts placement near the board edges, as the speaker magnet area has the least room for clearance. The protective coating on the foil can be scraped away at points needing the solder connections. Watch battery polarities and note that the Weatheradio schematic chassis symbol designates nine volts *positive*. Be sure to connect the positive lead of the squelch circuit to a point *after* the on/off switch so it does not draw current when the radio is turned off. A circuit modification or error on the Weatheradio schematic has pins 2 and 3 of audio amp IC2 reversed. Squelch output (from D2 and C3 of Fig. 2) goes to actual pin 2 of IC2. As each part is added to the board, it is a good idea to seat the board into position in the plastic case to check for parts clearance and to avoid shorting leads to the metal speaker. Care and patience cannot be overemphasized. It is quite easy to make optical reversals while looking at both sides of the board for circuit points of inductors and IC pin numbers. Triple check. Insert a milliam-

THERE IS A DIFFERENCE IN QUARTZ CRYSTALS

International's leadership in crystal design and production is synonymous with quality quartz crystals from 70 KHz to 160 MHz. Accurately controlled calibration and a long list of tests are made on the finished crystal prior to shipment.

That is why we guarantee International crystals against defects, material and workmanship for an unlimited time when used in equipment for which they were specifically made.

meter in series with one of the battery leads after the completed unit is in the case. If it draws more than 25-30 mA, recheck for shorts or solder bridges.

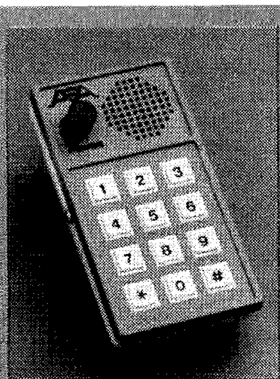
Final Touches

Frequency coverage of the tuning range can be increased or decreased by increasing or decreasing (respectively), by a few picofarads, C18 which couples the varicap tuning to the local oscillator. I made no modification here, as frequency coverage was adequate for the repeater portion of two meters. A tiny dot of white paint or nail polish on the tuning knob, with frequency-reference dots on the case, will prove useful. If you want to turn this into a deluxe model, drill a tiny hole on top of the plastic case and install a subminiature LED for an on/off indicator. At the expense of a slight increase in current drain, this feature will remind you to turn the radio off at night and might save you a battery. If space can be found to neatly install a small battery cut-off jack for an external nine-volt supply, it would do wonders for your budget; nine-volt batteries are not noted for their longevity. With a little ingenuity, the local oscillator could even be converted to single-channel crystal control.

My FM monitor keeps me in touch with what's going on without my having to pull my rig out of the car every evening. For a while, it also kept me from jumping in on every QSO. Eventually, I broke down and built a 50-mW companion FM transmitter which easily hits the local repeater. It measures only 1½ × 1 × 1 inches. So now I have a $25 hand-held, but—you guessed it—no matter how hard I tried, I couldn't squeeze it into the Weatheradio case. ■

LEARNING THE MORSE CODE?

Try the All New AEA BT-1 — Basic Trainer For Morse Code



AEA, in conjunction with ETS (Educational Technology and Services)*, has developed the BT-1 Code Trainer. ETS methodology, based upon research by a prominent mid-west university, has demonstrated that a typical student using this system and the BT-1 can learn Morse code to speeds of 20 WPM in four weeks based upon two 20 minute daily training sessions.

The pre-programmed BT-1 computerized trainer will allow you to achieve proficiency in Morse code faster than any other known method.

No prior knowledge of Morse code is required to use the BT-1. There are no tapes to purchase or wear out. The BT-1 operates from a 12 VDC source or from the AEA 117 Vac wall adapter unit, AC-2. For portable use the BT-1P is available with Nicad batteries and comes with a charger that operates from 117 Vac. The unit can also be used in mobile settings via the 12 VDC system.

The Secret Telemetry of OSCAR 8

Do those numbers from the sky mean anything? You bet.

Joe Magee K5OM
3928 Tacoma
Irving TX 75062

Do these numbers mean anything to you: 101, 245, 376, 449, 549, 601? Well, this is the data I received from OSCAR 8. Since first learning about amateur satellites with signals I could hear on my Kenwood R-599, I have often copied this type of data.

The above sequence, when decoded, says that the total solar-cell current was 0 mA, the battery current was −285 mA, the battery voltage was 15.85 volts, the base-plate and battery temperatures were 23.28° C, and the Mode J power output was 0 mW. The math is pretty simple, so the numbers are easy to calculate. A pocket calculator does the job in no time.

The data comes from OSCAR encoded into six different number groups. These groups are assembled into a certain order by OSCAR before transmission. Each number group is called a channel and the assembly is called a frame. Thus, the numbers above are considered as one frame. Each frame is separated from the rest by "HI." So, the frame above was actually copied as "101 245 376 449 549 601 HI."

Notice that each channel is composed of a three-digit number. The first digit tells what channel is being sent and the next two digits are the data for that channel. Each frame will always have all six channels.

The data is encoded in each channel. Since two digits can have only 100 different values, equations must be used to decode the data into something useful (see illustrations). In addition to the equations, graphs are presented so that you can get approximate values. You can locate the received values on

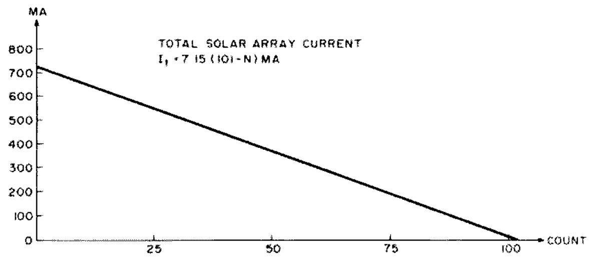

Fig. 1(a). Channel 1.

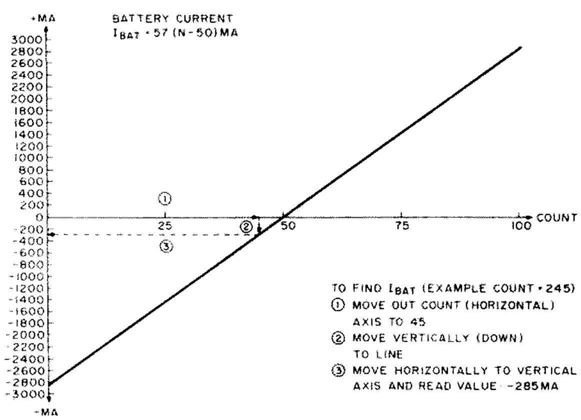

Fig. 1(b). Channel 2.

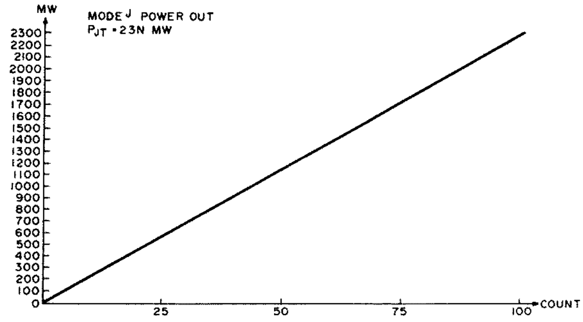

Fig. 1(e). Channel 6.

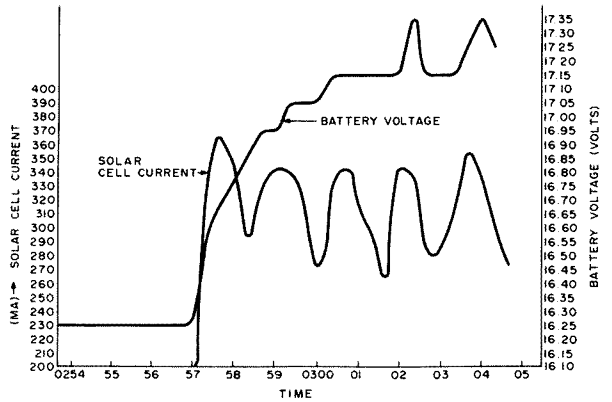

Fig. 2.

the horizontal axis and find the decoded values on the vertical axis—as is shown in Fig. 1(b).

Knowing the numbers still doesn't tell you what they mean. For instance, the 1xx sequence gives solar-cell current. Above, it was 0, but sometimes you may copy several sequences and the 1xx may change. This happens when OSCAR goes from light to dark or dark to light. Since this happens rather quickly, one should notice a dramatic change.

Once OSCAR is in the sunlight, a more subtle change should be noticed. The solar cells that are used to charge the batteries are mounted on the faces of the satellite. Thus, as it turns, the solar-cell output current will vary correspondingly. On April 17, 1979, during orbit 5683 (for example), I monitored the telemetry. I plotted the solar-array current (Fig. 2). The passage into the sun is clearly evident. Before passing into the sun, the 1xx data should be 00, 01, or 02. The 01 or 02 results from voltage offsets and counting errors. (Each channel is subject to a 1-count error.) Also, note any changes in the current resulting from the spin. As the sun shines on a corner, two sides are lighted, resulting in more current than if only one side were illuminated. Also, since there are four corners, there will be four current peaks per revolution. By looking at the graph in Fig. 2, we can see that OSCAR 8 was rotating once about every four or five minutes.

Channel 2 is a measure of the battery current. It tells how much current is flowing into the battery. When in the dark, with no solar-cell current, it will show how much current is being used by the satellite. This value, in conjunction with Channel 3 (battery voltage), can be used to determine the Mode A power output. Simply determine how many Watts the battery is delivering and then subtract 3 (the power consumed by the rest of the satellite except the Mode A transmitter). In my original example, the Mode A power is about 1.52 Watts (15.85 V times .285 A minus 3 Watts).

As mentioned, Channel 3 is the battery voltage. Out of curiosity, I plotted it along with the solar-cell current in Fig. 2. The rises in battery voltage corresponded to the peak current from the solar array, as one would expect.

Channels 4 and 5 measure temperature. Channel 4 is the base-plate temperature and 5 is battery temperature. The base-plate temperature will stay fairly constant when OSCAR is in the dark and will become warm in the sun. This warming will occur at various rates, depending on the angle of the sun in relation to the satellite.

The battery temperature can vary much more rapidly. As nicads are overcharged, their temperature rises. When in the sun, OSCAR will warm up from the sunshine and perhaps from battery heating as well. Battery temperature is important because high temperatures will cause cell damage. In space, there is no shade; thus, if the batteries start to overheat, something must be done to reduce charging current. This is most easily accomplished by putting the satellite into a high-power mode, such as Mode J, which draws more current from the battery.

Finally, Channel 6 is a measure of the Mode J power output. Naturally, it will show 00 (or 01 or 02 as does Channel 1) when in Mode A.

Working with the numbers once you have them isn't half as much fun as getting them. You must listen to OSCAR 8 as it makes a pass within range of your QTH. This procedure is covered well in other places, but if you are in the US, any evening Sunday through Thursday (except Tuesday) will be a Mode A night. Now, turn to the Table of Contents of your *73 Magazine* and find the page number for Satellites. By turning to that page you will find a listing of reference orbits for each day of the month (remember that

these dates and times are GMT). In general, you can hear two or three passes in any one evening. On Mode A, the telemetry is on 29.40 MHz. (The actual received frequency may vary a few kHz due to Doppler shift.) As OSCAR is approaching, the frequency will be high; it will be low as it is departing.

If your QTH is close enough to a particular orbit to hear OSCAR 8, you should hear some activity within one to five minutes after the predicted crossing time. The length of time that OSCAR is within range will vary, from less than five minutes to nearly twenty minutes.

One big problem with OSCAR is that it is addictive! I am torn between listening to either the telemetry or to QSOs. To help make the telemetry more fun, I wrote a program for my TI-59 calculator to perform the math needed to decode the data. For added interest and experience, the program that I wrote used the PC-100A print cradle with its 20-column thermal printer, providing an informative and permanent printout. The printout of the data in the first paragraph of this article is shown in Fig. 3.

Fig. 4 is a listing of the program. It is made up of three sections. Section 1, lines 000 through 029, is used to enter the data into the calculator memory for later use. In Section 2, lines 030 through 164, the OSCAR data is converted to the proper value. Lines 375 through 390 are a subroutine and are used to determine if the 1xx and 6xx values are very small, in which case they really should be 0.*

The last part, lines 165 through 374, is used to print out the answers. This is where the alphanumeric capabilities of the TI-59 are used. When printing out the

input data, a header is printed. This is accomplished by filling the print buffer with 40 numbers that correspond with the 20 characters that are to be printed (two numbers per character; sorry, not ASCII) and then issuing a print command (lines 166 through 215). In lines 217 through 234, the values are recalled and printed.

Another handy feature of the TI-59/PC-100A is the ability to print 4-character subscripts. The calculated data is output this way in lines 287 through 373 (236 to 285 are used to print the output header). This is done by putting the eight numbers which correspond to the characters in the subscript into the right-most segment of the print buffer, recalling the data from memory, and then printing the line.

I am glad that I had to tell the TI-59 how to do all this only once! From now on, I will just read the program in on a mag card. ■

We're changing what repeaters can do . . . for YOU!

Whether you're a repeater owner, control op, or user, the RC-850 controller offers you capabilities you've only dreamed of. Like natural sounding speech synthesis . . . easy, remote Touch-Tone programming . . . talking meter readback . . . synthesized remote base operation . . . and an autopatch with features you have to hear to believe.

Most important of all, upgrade through software, prevents obsolescense. Which lets us bring you new features, like our scheduler, for automatic changeover of repeater status by time and day of week . . . And our mailbox, for leaving messages for your friends. Plus much, much more!

The RC-850 Repeater Controller—The New Standard in High Performance!

Ask anyone that owns an RC-850 controller. Or ask us for our demo tape, so you can hear for yourself.

Scandinavia: The 2-Meter Dream Vacation

Licensing, frequencies, and procedures—it's all here. All you need is a plane ticket.

Pack your bags for a great Scandinavian vacation! The land of the midnight sun beckons and it's more fun with 2 meters. If you want to take that rig with you, plan in advance.

Getting Your Licenses

You need sufficient time for processing through the FCC, the Scandinavian authorities, and for any international mail delays. Allow 6 months if possible. Send the ARRL (225 Main Street, Newington, Connecticut 06111, Attn: International Affairs) an 8½" by 11" SASE and they will send you application forms for each country. If time is short, Fig. 1 is a form which includes all of the necessary information for each country. The address for each licensing authority is also given.

For each country (except Finland, where the form is sent directly to SRAL), send the completed form to the FCC requesting endorsement and forwarding. Enclose a stamped airmail envelope addressed to the proper foreign authority. If you furnish an SASE, the FCC will confirm the date on which your papers were mailed. Send to: FCC, PO Box 441, Gettysburg, Pennsylvania 17325.

TO: (See Below for Addressee)

APPLICATION FOR PERMISSION TO OPERATE AN AMATEUR RADIO STATION IN ____________ (Country)

I, the undersigned, hereby respectfully apply for a temporary permit or license to operate an amateur radio transmitter in ____________

License period requested: ____________
Name in full: ____________ Occupation ____________
Address in my own country: ____________
Date and place of birth: ____________
Nationality: ____________
Call Sign: ____________ License Class: ____________ Expires: ____________
Address in ____________: ____________

Fig. 1. Sample form for requesting license to operate in a foreign country.

Look for me on 2m as I drive around Scandinavia in April. I'm open for ham talks in Copenhagen 3-5th April; Oslo, 6-9th; and Stockholm, 10-13th. If there is any interest, please get in touch.—Wayne Green W2NSD/1.

Denmark. Application should be filed at least a month before the requested license period. Attach a photocopy of your license. Within a few weeks you will receive the license and a payment form. When you arrive in Denmark, go to the nearest post office, pay the fee (only 20 kroner for a short stay), and your license is then valid. A temporary license will be issued for up to three months.

In Copenhagen, there is 24-hour service at the post office in the Central Railroad Station. This is right in the center of the city, next to Tivoli Gardens.

When applying for your license in any country, if you do not know the exact dates of your arrival and departure, allow a few extra days on each end. If you have no references in the country, enter "none" on the reference line.

Norway. In addition to a copy of your license, Nor-

way requires a "certificate of good conduct" from your local police department. This can be a letter on police department stationery stating that you are of good character and reputation and that the police know of no reason why you should not be issued an amateur license in Norway. Your application should be on file at least a month before the operating period requested. A temporary license will be issued for up to three months.

The fee of 50 Norwegian kroner must be sent with your application. Buy an international draft or money order payable in Norwegian currency. If you send a personal check or dollar instrument, you may cause substantial delay or return of your application. I suggest that you staple *all* of the documents together.

Sweden. A police good-conduct letter is required for Sweden just as in Norway. Your application should be filed at least two months prior to the requested license period. The Swedish authorities will send you a license with a request for any fees. Fees can be paid by mail or upon arrival in Sweden at a post office. The fee will vary with the length of the requested license period.

Finland. The amateur society, SRAL, handles all license applications. SRAL tells you to allow at least 4 to 8 weeks, more in summer, for issuance. It took me considerably longer than 8 weeks. If your license is for less than one month, a fee of 58 markka must be paid with your application. This includes the processing charge by SRAL. For a license for more than a month, you must join SRAL and the fee is higher. The maximum temporary license period is three months, subject to renewal. Your mailing address in Finland must be given exactly. This may be the address of your hotel.

You must furnish a copy of those pages of your passport containing personal data and of your amateur license certified by two signatures. I photocopied my amateur license and the pages of my passport with my name, date of birth, etc., and my picture onto a single sheet. At the bottom I typed this certification: "Each of the undersigned certifies that he has examined original passport No. ______ and the amateur radio license of Charles R. Perelman and that the above are true and correct copies. Executed on______, 1981, at Beverly Hills, California, under penalty of perjury." Two signatures followed.

Each country will send you a translated copy of rules and regulations. Your license will bear your home call with the appropriate country designation, for example: WA6OGW/OZ. Low-band and UHF privileges will depend upon the class of license you hold in your home country. In Denmark, Norway, and Sweden, you

are permitted to work mobile. Although local amateurs have been working diligently to obtain this privilege for visiting amateurs in Finland, at this time non-residents are not permitted to operate mobile in Finland.

Gear to Pack

If you are traveling other than by car, a synthesized handie-talkie would certainly be the most versatile rig. In the older crystal-controlled radios, the Kenwood TR-2200 (same as the Drake TR-22) with sockets for 12 channels will permit you to crystal up for the 10 repeater channels and two popular simplex channels. However, unless you already have some of the crystals on hand, the cost of all those rocks will probably convince you to buy a synthesized rig.

Scanning is useful, particularly if you will be operating mobile. Even though you may have looked up the local repeater frequencies, changes do occur; you may not know exactly where some of the repeater sites are located or the extent of coverage of some repeaters, or you may desire to check simplex channels.

I suggest that you take the following in addition to your 2-meter rig:

- Mag mount and cigarette-lighter power-supply cord for mobile use.
- Quarter-wave or 5/8-wave telescoping antenna for HT. You may be in a poor location or want to extend the range beyond that feasible with a rubber ducky.
- Shortened or flex-type rubber ducky. If you carry the HT on your belt, both the rig and antenna are less likely to be damaged if either of these types of antennas are substituted for the regular rubber ducky.
- Battery charger and transformer or solid-state converter for 220 volts to 110 with sufficient wattage rating. Conversion plug with large round prongs. Some hotels furnish a 110 outlet for shavers which can be used to charge HT batteries. Ordinary wall outlets are 220 volts, 50 cycles requireing the round prongs and converter or transformer.
- 1750 tone burst with duration of at least 1 second. Some repeaters are carrier-operated. Most require the 1750 tone burst. Length of burst required appears to be longer than typical in some other parts of Europe. You may be able to obtain a whistle from a friend in Scandinavia which will produce the 1750 tone. It looks like a single pitch pipe.

If you are a good whistler, unless your musical talents are sufficient to approximate 2 octaves higher than A (440 Hertz) above middle C, the technique is to start high and slowly descend in pitch to be sure you've covered the right frequency. This sounds something like the second part of the whistle when you gaze approvingly at one of the local beautiful blonde blue-eyed YLs. If all else fails, you can still get into the repeater after a local ham has accessed it with the tone burst.

- Earphone. There are times when people on a bus, the street, or elsewhere may not take too kindly to the sounds of the QSO you may be holding with a local amateur. This is particularly true if there is a lot of noise coming in with his signal. The earphone solves these problems.

To avoid possible customs questions, either upon entry into one of the Scandinavian countries or when returning to the US, it is a good idea to register your radio gear (and cameras as well) with US customs. Call your local customs office to find the location for this service. It only takes a couple of minutes to fill out the form which will be stamped and inserted into your passport. In Los Angeles this can be done at a little cubicle on the second floor of Los Angeles International Airport.

Repeater Frequencies

Fig. 2 lists the repeater frequencies and most-often-used simplex frequencies for 2 meters. Fig. 3 contains information on UHF repeaters. Most of these are located in Sweden and follow the Swedish band plan with a 4.6-MHz separation rather than the typical 1.6-MHz separation used elsewhere. With my Kenwood 2400, I found it most convenient to program the 10 repeater channels into memories 0 through 9. Scanning the memory channels would then locate an active repeater. As in the United States, the repeaters are busier in the morning just before working hours and in the evening than they are during the working day. However, the level of activity appears to be considerably less than on a busy repeater in one of our metropolitan areas.

During the summer months, working hours often begin at 7 or 8 am and end by 4 pm. The first three weeks in July are usually an "industrial holiday," vacation for much of the work force. This often means deserting the city for a cottage in the country or at the coast. If you want to be sure to make contact with a particular ham, by all means arrange your meeting in advance. Use the low bands or a letter before your trip to be sure of his or her location when you will be in his country.

Fig. 4 contains information on the location of 2-meter repeaters in each of the Scandinavian countries. With the harsh winters, antennas are often damaged so that some of the stations may be off the air at times. Fig. 5 shows locations of UHF repeaters.

Enjoying Your Fellow Hams

For information on everything from directions to a Chinese restaurant (yes, there are some in Scandinavia) to an interesting art exhibit, try your friendly local repeater. As elsewhere in Europe, many of the hams save pins, banners, or patches from radio societies of other countries. This kind of item makes a nice token

Fig. 5. UHF repeaters in Scandinavia.

gift. Yaesu and Kenwood rigs are widely used and you make a friend for life by obtaining a needed service manual for a Scandinavian ham. If a radio friend is contemplating a trip to the US, he may appreciate a repeater directory or road maps. An auto club is the best source for maps.

I think the most enjoyable contact in a foreign country is with a ham with whom you've talked on the low bands. When your itinerary is firm, set up a definite rendezvous. You will probably learn more about life in that country in an evening than during the rest of your trip.

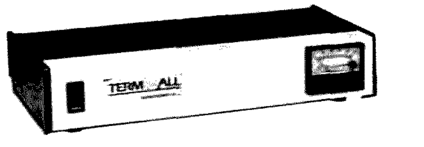
Chance contacts resulting in bending elbows together at one of the local pubs can make new friends and be a lot of fun as well. However, alcohol and driving definitely don't mix in Scandinavia. Penalties for driving with even a very small quantity of alcohol in the blood are severe. Therefore, expect your friend to pass up the beer for a soft drink if he is driving.

In Copenhagen, don't be surprised to have Swedish stations from Malmo, Falkenberg, or some of the other southern towns come back to you through the local repeaters. In Finland, the repeaters in the less populous parts of the country, north of Hameenlinna, Tampere, and Lahti, may not be operational from time to time. You should check this out through low-band QSOs if you are planning to travel in the more northerly areas.

Two meters can be your key to opening up better paths of understanding of the beautiful countries and people of Scandinavia. Plan ahead, make new friends on the low bands, and have the fun of eyeball QSOs far from home. You will learn more, have more fun, and have some unforgettable memories through the power of amateur radio. ■

TERMINALL

RADIO MODEM



apple* TRS-80* ATARI*

SEND & RECEIVE CW & RTTY

TERMINALL is a hardware and software system which converts your Personal Computer into a state of the art communications terminal.

- TERMINALL is easy to use. Plug into your receiver headphone jack and copy Morse code or radioteletype. Plug into your CW key jack and send Morse code. Attach a Microphone connector and send Baudot or ASCII RTTY using audio tones (AFSK). That's all there is to hooking it up.
- Fantastic Morse reception. No adjustments are necessary to receive Morse code. It's *fully automatic!* Six stage active filter demodulator and auto adaptive Morse algorithm copies the weak and sloppy ones.
- Separate RTTY and CW demodulators. Built in crystal controlled AFSK. CW and PTT keying. 60 ma loop interconnect. RS 232 IN and OUT. hand key input and side tone output.
- Built in parallel printer driver software allows hardcopy in all modes.
- Hardware clock maintains accurate time.
- Multiple user defined WRU functions. You select initiate sequence, terminate sequence, what to transmit back and whether to save on tape or disk.
- Word wrapping, word mode editing, diddle, ignore carriage returns, user programmable end of line sequence, adjustable carriage width, transmit delay (fixed, none or auto adaptive), excellent documentation, break mode and much more.
- TERMINALL has capabilities far surpassing dedicated terminal systems. And since it works on a general purpose computer, the *majority of your investment (your computer)* is spread out over many different applications. **You get more for your money.**
- Complete with software on cassette and diskette, assembled and tested hardware, and extensive instruction manual. Call or write for specifications on TERMINALL for TRS-80 Model I or Model III, Apple or ATARI 400/800 COMPUTERS. $499
- 15 day money back trial period. One year parts and labor limited warranty on factory direct orders.

Twisted Remote Control

This circuit is easy to build and easy to use.
The twist is that you probably own the most important part.

Described here is a simple and inexpensive remote-control system, the major component of which you probably already have on hand: an AM-FM receiver, either portable or table model. As with any remote-control system, it has many uses. It may be used as a television commercial killer, to turn on or off a distant light, etc.

If you have tried to build any of the light-operated-relay type of remote-control devices in the past, you must surely have noted two distinct disadvantages of that type of system: 1) They are usually very sensitive to ambient light levels and therefore difficult to adjust, and 2) You must be able to see the device in order to control it. Since this system uses radio waves as the controlling medium, these drawbacks are readily overcome.

Receiver-Transmitter

It is certainly not difficult to generate a low-power rf signal that can be used for remote control, but the difficulty begins when trying to design and build a receiver with sufficient gain to amplify the low-power signal to a usable level. To circumvent this problem, a conventional table model or portable-type AM-FM receiver can be used along with a tone-modulated FM wireless microphone to generate the control signal.

Switching Circuit

With the problem of the receiver-transmitter solved, all that is needed is a switching circuit that can be operated by an audio tone taken from the receiver. The circuit shown in Fig. 1 does this job very nicely.

The heart of the switching circuit is U2, the CMOS 4027 J-K flip-flop. This particular type of flip-flop has the unique characteristic that if both the J and K inputs are held in a high state and a clock pulse is applied to the clock input, the output will toggle to a high or low depending on its previous state. The output will continue to toggle back and forth as long as clock pulses are applied to the clock input.

Referring to Fig. 1, assume that the output of U2 is in a low state and Q2 is off. Also assume that the primary of T1 is plugged into the earphone jack of an FM receiver tuned to the operating frequency of the wireless microphone. When the transmitter (wireless microphone) is momentarily turned on, an audio pulse is applied to the primary of T1. This audio pulse is then rectified and used to forward bias Q1. With Q1 momentarily turned on, a negative-going trigger pulse is seen at the trigger input of U1 (used here as a one-shot).

This trigger pulse causes the output of U1 to switch to a high state where it will remain for a period of time determined by the series combination of R1 and C2 (in this case about 1 second). This positive-going

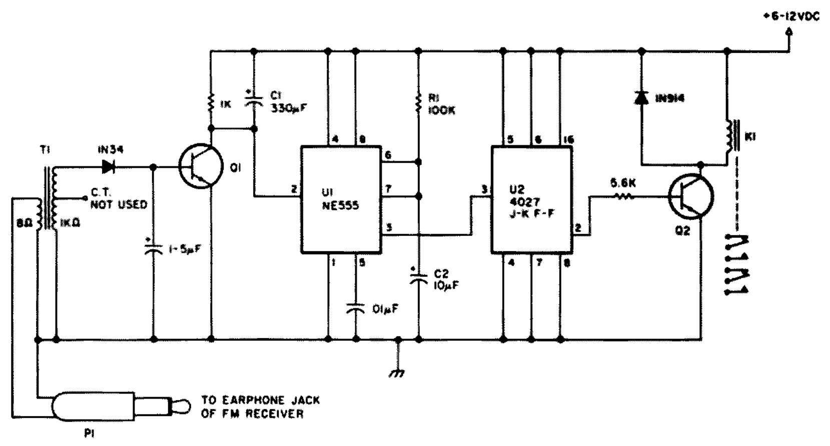

Fig. 1. Schematic diagram of the switching circuit. The transistors and transformers used in both circuits are 2N2222 or Radio Shack 2009 and Radio Shack 273-1380, respectively.

pulse at the output of U1 is applied to the clock input of U2, causing the output of U2 to toggle to a high state which turns on Q2 and energizes relay K1. The output of U2 will remain high until another pulse is applied to the clock input, at which time it will toggle back to its original low state.

Since the limiting action of most inexpensive FM receivers is not what it should be, C1 (connected across the Q1 collector resistor) is included to prevent possible false triggering caused by noise spikes from the output of the receiver.

No power supply is shown in Fig. 1, since these have been extensively covered elsewhere in the ham literature. As shown, any voltage from 6 to 12 volts will work. The amount of supply voltage you decide to use will depend upon the voltage rating of the relay you purchase, or that of one you may have on hand.

It should be mentioned here that the receiver you use must have some type of external antenna, and an earphone jack. If your receiver has no earphone jack, one must be added, which is simple to do using a three-conductor phone jack.

Transmitter Circuit

The FM wireless microphone circuit shown in Fig. 2 was originally published in the April, 1969, issue of *Popular Electronics*. The circuit, as shown in that issue, used an RCA KD-2114 linear IC for the active device but discrete transistors were used here since they were more readily available. The circuit is shown here with one modification; the microphone input network has been replaced with a simple tone-generating circuit composed of R1, C1, Q1, and T1. It has an output of about 800 Hz and provides the necessary control signal.

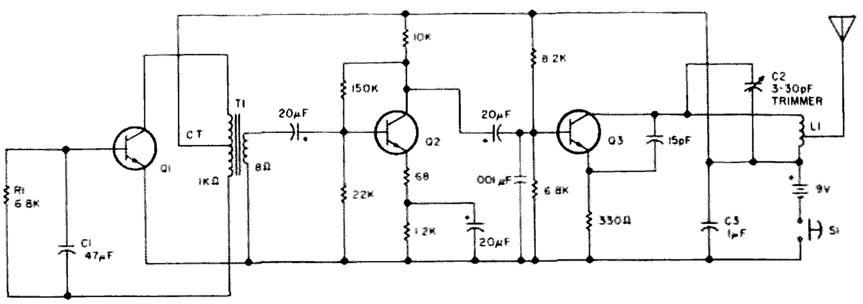

Fig. 2. Schematic diagram of the transmitter. See text for L1 dimensions.

Switching Unit and Transmitter Construction

The switching unit can be built most easily using perfboard construction, and sockets should be used for both U1 and U2, in case replacement becomes necessary. The unit may be enclosed in any type of case you may have on hand.

Perfboard construction also may be used for the transmitter, although I have used the PC board square block method with good success. This means using a hacksaw to cut the foil side of a piece of PC board into squares and mounting the components on the squares. Placement of parts in the transmitter is not too critical, but an orderly in-line layout ought to be used. The connections in the rf portion of the circuit should be kept as short and as direct as possible.

Coil L1 consists of 6 turns of #12 tinned copper wire with an inside diameter of 5/16 inches and spread to 3/4 inches in length. The antenna tap is made one and one-half turns from the cold, C3, side, and tuning capacitor C2 is soldered directly to the top and side of the first and last turns of the coil. Coil L1 should be mounted as firmly to the board as possible to enhance frequency stability. The antenna can be fashioned from a piece of heavy-gauge copper wire, and can be anywhere from 3 to 12 inches in length. A plastic case similar to those sold by Radio Shack can be used for housing the transmitter.

Test and Adjustment

First, the transmitter should be tested and adjusted to a clear operating frequency. To do so, turn on your FM receiver and tune for a clear spot on the dial. The afc should be turned off, if possible, to prevent the receiver from tuning automatically to a strong adjacent channel. Once a clear spot is found, apply power to the transmitter and adjust tuning capacitor C2 until an audio tone is heard from the receiver. Now, either continue adjusting C2 or vary the tuning of the receiver until the purest tone possible is obtained.

The switching unit may now be tested for proper operation. Plug P1 into the earphone jack of your FM receiver and apply power to the switching unit. At this point, the volume control of the receiver should be set at some low level. Each time the transmitter is momentarily activated, the relay on the switching unit should energize and stay energized until a second pulse is transmitted, at which time it will return to its normally-closed position. The volume control may have to be increased a small amount to ensure reliable operation at a distance.

If the switching unit does not operate as just described, then either a wiring error has been made or one of the active devices is defective.

The range of the transmitter will vary with operating conditions and depends to a certain extent upon the orientation of both the transmitting and receiving antennas. It has been my experience that reliable operation can be had with distances up to 75 feet.

Summary

The uses that may be found for this simple system are many and are limited only by your imagination. If you happen to own a video tape recorder and like to record movies *without* the commercials, then this remote-control system can be used to pause the recorder and to cut them out. It could also be used as a commercial killer for the television itself. To use it this way, one of the television's speaker leads is broken and connected to a set of the relay's normally-closed contacts. In fact, you might even connect your ham-band receiver's mute terminals to the relay's other set of contacts, and that way be able to listen to it while the television sound is off.

There are, undoubtedly, many other applications that can be thought of, but whatever you may use it for, always be careful to observe the relay's contact power rating, otherwise an expensive relay may be ruined. ■

Take Your IC's Temperature

Like people, solid-state devices get sick if they get too hot. W3KBM provides a way to answer the burning question, "How hot is hot?"

Allen S. Joffe W3KBM
1005 Twining Road
Dresher PA 19025

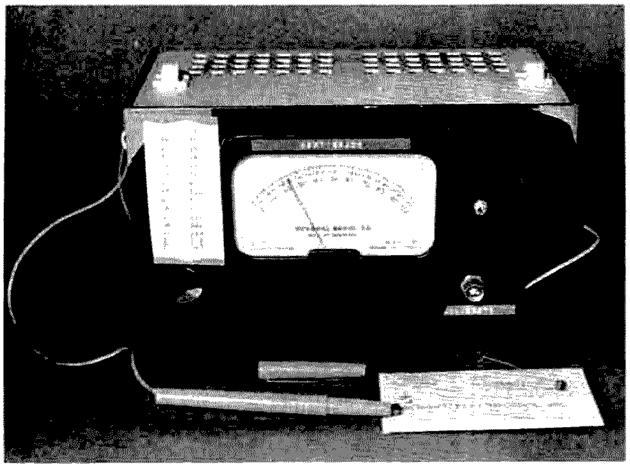
By now solid-state devices are old hat. We all know that too much heat is one good way to send such a device to semiconductor heaven. Since touching a hot transistor or IC with a finger either makes for one big "ouch" or leaves the question of "How hot is it?" largely unanswered, here is some surplus to the rescue.

Digital Research of Garland, Texas, has advertised "Thermistors . . . 5000 Ohms at 25 degrees centigrade," four for a buck. Upon arrival they proved to be Fenwal KA35J3 thermistors.

A quick trip to Herbach and Rademan in Philadelphia produced a surplus cabinet and a nice 200-microampere meter with a scale calibrated from 0 to 100. With the addition of very few parts, this collection was turned into a solid-state centigrade thermometer that allows me to answer "How hot is my IC?" very adequately.

The schematic in Fig. 1 shows the simplicity of the electrical hookup. Resistors R1 and R2 of the bridge should be as closely matched in value as possible. They can range from 4700 to 5000 Ohms; the important part of the matter is that they be as alike in value as possible.

Photo by Ira Joffe WA3PTC



Completed meter with probe attached.

Resistor R3 should be as close to the indicated 15k as you can get. The significance of R3 lies in the fact that at zero degrees centigrade the thermistor resistance will be rather close to this value. My four samples checked out this way as indicated by a fairly good digital meter. Thus, at zero degrees, the bridge will be balanced and the meter should read zero. Taking this route eliminates the need for a low-end calibrating element in the circuit. I used a fresh D-cell to drive the bridge; since the current drain is very low, the useful life of the battery should approach its shelf life.

My meter is 200 microamperes full scale, which is about the practical limit of usable sensitivity in the upward direction. That is to say, if you have a more sensitive meter, then use it, but avoid using a less sensitive meter. The reason for this is that even small currents flowing through the thermistor tend to produce "self heat" which changes its ohmic value just as much as heat from a device being measured. If you use a 50-microampere movement, you may have to increase the value of the variable resistor in series with the meter movement. This resistor is used as the sole calibrating element for the thermometer.

The photo shows the finished meter with its probe and also an unmounted thermistor which gives an indication of the size of this circuit element.

Now for some notes on the probe construction. The body of the probe was made from a discarded fiber-tipped type of marker such as a Flair or other brand. The point was pulled off and the residual ink was carefully wiped out of the barrel. I say carefully as there is enough ink left to ruin several sets of clothes, soil your hands, and provide some interesting comments from the family if care is not used in this regard.

The sides of the thermistor are painted with clear nail polish where the leads are attached. The same treatment is given to the first half inch of lead length near the body of the thermistor after a suitable length of cable

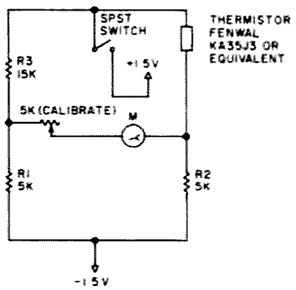


Fig. 1. Schematic diagram of meter.

has been soldered to the extreme ends of the leads.

The cable is then threaded through the empty pen body and the thermistor is checked for a good snug fit in the open end as shown in the photo. If you have to ream out the end a bit to achieve a snug fit, by all means do so. When this has been done, pull the thermistor and cable out an inch or so and work some artificial rubber compound like GE silicone seal into the end of the probe barrel. Pull the thermistor back in, seat it nicely, and put the assembly aside to dry. You may also want to use the silicone seal in the end of the probe from which the cable exits to provide a bit of strain relief. That is all there is to the probe.

When the construction of the probe and associated circuitry is finished, turn on the switch and the meter should be reading somewhere about 20 to 25 degrees on the meter face. Turning the calibration control should allow a meter variation of about eight to ten degrees total.

It may pay to make a "big deal" out of the initial calibration so you can see that it works. The big deal is as follows. Obtain a reliable thermometer such as a unit used to check the temperature of photographic solutions. Fill a jar with hot water from the kitchen tap. Check its temperature with your known good thermometer. Add a bit of cold water if necessary to get the water to about 120 to 125 degrees Fahrenheit. After this thermometer reading has stabilized for about one minute, gently place your thermistor probe into the water so that it just dimples the surface of the water. Give the meter a chance to settle to a reading, which may take as much as thirty seconds to ensure that a maximum has been reached. Multiply your meter reading by 1.8 and add 32 to the result to convert the meter reading to Fahrenheit degrees as shown on your comparison thermometer. If it is high or low, make an adjustment with the calibrating pot so that the two readings coincide.

If you do not want to go through the "big deal" version of calibration, then use one of the best thermal standards around. That standard is you and the normal temperature of your body, which is just about 98.6 degrees Fahrenheit or 37 degrees centigrade. Touch the tip of the probe to your tongue and hold it there until the meter reading stabilizes. Set the calibration control for a reading of 37 degrees on the meter and you are done. This is one instrument where you will never lose the source of calibration.

Do not use this thermistor thermometer to take the temperature of hot liquids. Use it for its intended purpose of measuring the temperature of ICs and discrete semiconductors. When you do this, I suggest that you take a small bit of thermal compound such as you would use on a power transistor to make sure that it is in good thermal contact with a heat sink. Place this on the semiconductor or IC of interest and then apply the probe tip to it so that you have good thermal contact with the subject at hand. This should give you reliable comparative readings. You can easily see the effect of different sizes and materials of heat sinks in terms of getting rid of heat from the power devices. Please note the use of the phrase "reliable comparative" readings. This simple device will not put the National Bureau of Standards out of work, but it is a nice adjunct to aid any ham working with power semiconductor devices. ■

THE RTTY ANSWER

The Q-Master Cavity Filter

A high-Q filter that uses no copper and no silver-plating—just coffee cans and some ingenious thinking.

A few months ago, some experimental work I was doing with a low-power, home-brew repeater system required a sharp filter to restrict the bandwidth of the signal presented to the antenna terminals of the receiver section, particularly at the transmitter frequency. Since the cost and availability of commercially-produced cavities were prohibitive, I decided to research the problem and see if I could make my own.

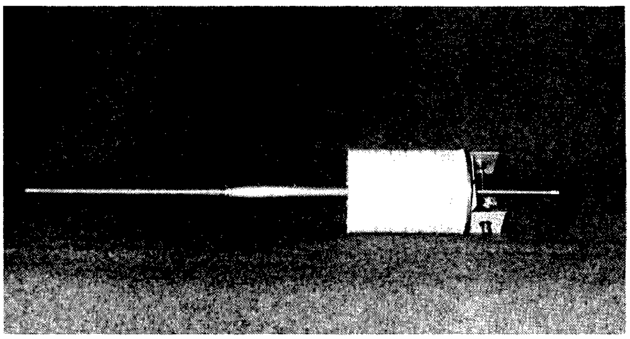
Several of the amateur publications, engineering texts, and reference books in my library discussed the subject (see reference list at end of article); some even gave dimensions and bills of materials. Since I live in a somewhat remote part of the Pacific Northwest, availability of many of the materials specified and machining services required was a problem. I decided that I should tackle the problem with the idea of using only readily-available parts and home-brew construction techniques and see what could be done. This is the story of that effort.

First, it was necessary for me to determine just how a cavity operates and what the critical conditions were. Research showed that the cavity is merely a tuned circuit, consisting of a quarter-wave stub centered in an enclosure. The combination results in a well-shielded, high-Q filter when inserted in series with the transmission line. As with any tuned circuit, the circulating currents are quite high at resonance, so losses must be kept low to ensure high Q. The losses are generally the result of the resistance of the materials from which the cavity is made. For this reason, most commercial units are made of brass or copper and silver-plated.

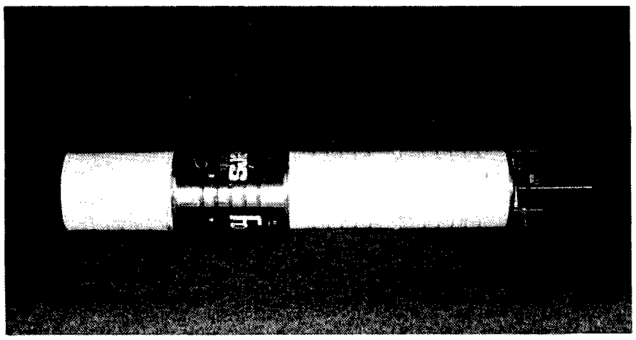
Coupling into and out of the cavity can be accomplished by any of several means, but the most common is inductive coupling, whereby small loops are positioned near the inner stub and act as transformer windings in relation to it. The loops are mounted on opposite sides of the stub so that there is minimum direct coupling between them. Thus, the input loop induces the signal into the stub (which is, remember, part of a resonant circuit), and the stub in turn induces the signal into the output loop. Since the response of the resonant circuit is appreciable only at or near the resonant frequency, appreciable coupling between the input and output loops occurs only in that range, and we have a bandpass filter.

Fig. 1 shows the low-frequency equivalent of the cavity filter, using discrete coils and a capacitor, and may help the reader to understand the operation of the circuit.

In order to build the device with a reasonable chance of success, it is necessary to identify the critical areas first. Obviously, the length of the center stub is critical. It must be an electrical quarter wave-



First coffee can soldered to the top plate. Note the telescoping tuning stub.



Overall view of the two-meter coffee filter. One can was left unpainted for effect.

length long and, since this dimension is influenced by conducting materials near it, we must make it adjustable so that we can tune it precisely to the desired frequency.

Also, we must minimize the losses to maintain high Q and the sharpness of the filter. Silver-plating was out—for economic as well as practical reasons. Previous research showed that silver-plating at two-meter frequencies yields only marginal improvement—unless the plating is very heavy, the signal still penetrates beyond it to the base metal. Several articles on homemade cavities reported using brass or copper with apparently satisfactory results.

Another way to reduce the losses when the housing of the device is a relatively high resistance material is to increase the spacing between the stub and the housing, thus reducing the magnitude of the induced currents and hence the losses; however, the impedance of the circuit is also dependent upon these dimensions. The question, then, was how to ensure a proper impedance match into and out of the completed cavity filter. None of the references available covered this point; they only gave dimensions that had been used and worked, but did not back them up with theory so that the effects of variations could be determined.

A little more thought provided the answer, though. If the input and output coupling loops were made identical and mounted so that the relationship of each to the stub was identical to the other, the problem would be solved without even knowing what the stub/cavity combination impedance was. It would be like two identical transformers connected back to back—the load impedance would be transformed to

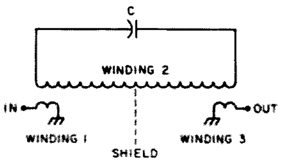


Fig. 1. Equivalent circuit of cavity filter.

whatever the stub/cavity combination required and then back down to the same impedance level in the other coupling loop.

With this encouraging reasoning, construction was begun. A source of brass tubing, of thin wall but quite rigid, was found at the local hobby shop. It comes in varying diameters and 12″ (30.48-cm) lengths and is not expensive in the quantities required. I used a 1″(2.54-cm)-diameter length for the upper section of the stub, and a ¾″(1.91-cm)-diameter length for the lower section, so that they could telescope together, allowing the length of the completed stub to be varied as required.

Since circulating currents in any resonant circuit can be quite high, as mentioned earlier, it appeared essential that the two sections be in very good electrical contact at all times. I used some finger stock from the junk box for this purpose, soldering it to the bottom of the upper tube and another piece to the top of the lower one. In this manner, when the two were telescoped together, we not only had good electrical connection, but also the smaller tube was held centered in the larger. The brass tubing used, however, is sufficiently "springy" that the finger stock is not necessary. You can simply saw a number of narrow slits in the ends of the tubing and form the fingers from the resulting tabs. It is a good idea to deburr the fingers thus formed with steel wool and to form slight "hooks" in them so that the contact is not made by sharp corners that

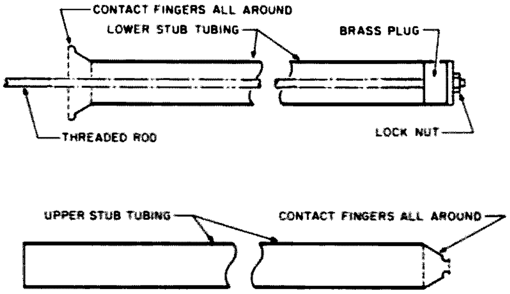

Fig. 2. Details of tuning stub construction.

might bind and hinder adjustment. Fig. 2 shows both the upper and lower stub assemblies in greater detail, including the homemade finger contacts.

Adjustment of the length of the assembled stub is accomplished by means of a threaded rod from the local hardware store. I chose a ¼-20 size. It is secured to the bottom of the inner stub section by means of a brass plumbing fitting. I chose one just slightly larger than the inside diameter of the stub tubing; I ground and filed it down to a snug fit and used it as the plug shown in the drawing. It is soldered to the stub and a nut, threaded over the end of the shaft, is soldered to it, thus ensuring that the threaded shaft is fairly well centered in the stub for smooth operation when tuning. Any of several standard brass plumbing fittings, such as adaptors to couple one size of pipe to another, will be satisfactory. Note that the threaded rod is soldered to the plug and the nut so that it may turn in relation to them.

A top plate for the cavity was made from some 1/16″ (0.64-cm)-thick copper plate I had on hand. Any material could be used that is a good conductor, but brass, copper, or aluminum would be best. The latter, however, would require different (and probably difficult) methods for making mechanical and electrical connections to it; the copper or brass stock allows soldering them directly to it.

A clearance hole for the threaded rod was drilled in the center of the top plate and a suitably-sized nut soldered over it. The two sections of the stub were assembled and the threaded rod screwed into that nut. The upper tube of the stub assembly was then soldered to the top plate, centered as closely as I could manage.

A note here about soldering these pieces together: Trying to accomplish this task with a torch or large soldering iron proved difficult. Either I couldn't heat the entire assembly enough to get a good solder connection or it was heated so much that previously sol-

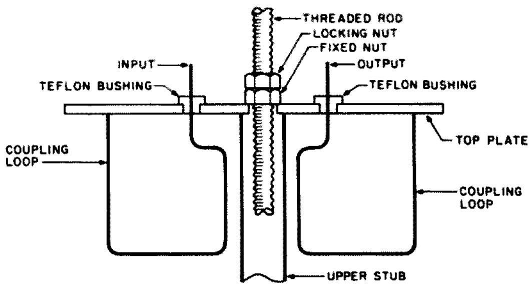

Fig. 3. Top plate assembly.

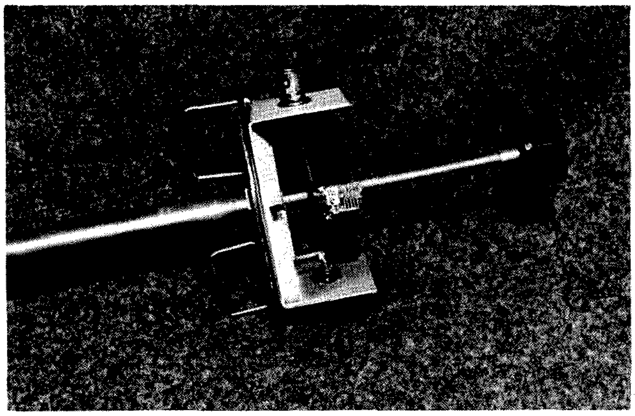
dered parts came loose. The solution was to preheat the material in the kitchen oven to some temperature below the softening point of the solder; then a relatively small iron could be used to attach new pieces, without heating the surrounding area sufficiently to loosen previously-made joints.

The coupling loops were formed from 1/16" (0.64-cm) brass tubing from the same hobby shop source. They are formed to be 1¼" (3.18 cm) wide overall by 1½" (3.81 cm) high, with extra material on the inner leg to protrude through the top plate, allowing for connection to the outside world. The offset shown in the accompanying drawings was used to provide clearance between the loop and stub adjustment screw as they came through the top plate and is ½" (1.27 cm) in sjze. I used a Teflon™ bushing, as shown in Fig. 3, to insulate the inner end of each loop where it passed through the top plate, but if not available, one could be fashioned from almost any scrap plastic. Be very careful that each loop is identical to the other and that both are mounted in an identical manner so that the impedance transformation for each is correct, as mentioned earlier.



Close-up of the tuning stub, coupling loops, and shunt capacitor.

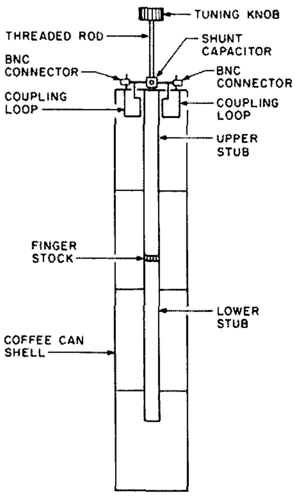


Fig. 4. Cutaway view, assembled cavity filter. The trimmer capacitor used to insert a notch in the response curve is included.

The two loops were soldered to the top plate, positioned so that their inner side cleared the stub by ¼" (0.64 cm), as shown in Fig. 3. It will be easier to position them accurately if a hole is drilled in the top plate where the outer leg of the loops should go and then the loops are soldered in these holes.

Next, I was faced with the problem of finding a suitable outer housing for the cavity. The construction articles in the references available included one calling for a 4"(10.16-cm)-diameter copper pipe for this material, 22½" (57.15 cm) long. Such pipe is not readily available in my area and has to be ordered from some distance away. Also, it is available only in much greater lengths than required and is relatively expensive. I decided to find an alternative.

A search of the local hardware stores yielded nothing that would be adequate. Then, one day while doing my grocery shopping, I noticed that some brands of coffee came in one-pound cans that appeared to be about the desired diameter! Eureka! Remember the "beer-can" antennas of some years back? I had found my source of material for the cavity. The only question was if the tin-plated steel cans would have too much loss to be usable. I decided to try and see.

I wanted new cans that weren't corroded or dented; this meant stocking up on quite a bit of coffee. I decided to try four cans, giving an overall length of 22" (55.88 cm). After storing the fresh coffee in everything I could find in the kitchen, I proceeded to cut both ends out of three of the cans and leave the bottom in the other. They were soldered end-to-end, and then the open end was soldered to the underside of the top plate, centered on the stub.

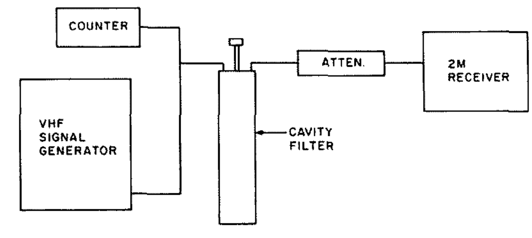

Fig. 5. Test setup for tuning and evaluating the cavity filter.

The addition of a small aluminum box to the outside of the top plate and mounting two BNC connectors on its ends allowed connection to be made to the ends of the coupling loops. Adding a second nut to the threaded shaft to allow it to be locked in place after tuning and a knob to the top of the threaded shaft to make it easier to adjust completed the job. I had a cavity filter, but would it work?

Fig. 4 shows a cutaway view of the entire assembly and may be of use to those desiring to build their own cavity filter.

Tuning the filter and evaluating its performance showed promise of being a problem without the availability of a well-equipped laboratory. I had an old VHF signal generator and a frequency counter available; that combination would serve as an adequate source with precise frequency calibration. The signal generator had an output meter so I could keep the input signal constant, and valid measurements could thus be made. But I needed a detector to permit measurement of the output of the filter. If the attenuation of the filter was anywhere near as great as it should be, I would be trying to measure signal levels far below those readable on a VTVM with *an rf* probe.

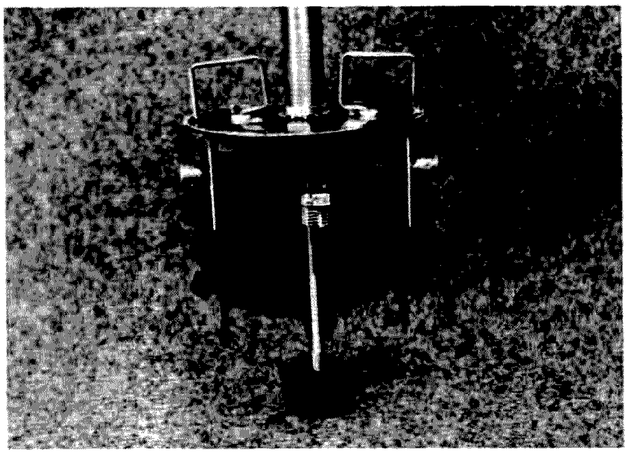
Finally, I borrowed a technique used by hidden transmitter hunters—I used a two-meter receiver with an S-meter and a calibrated step attenuator between it and the filter to keep the signal out of the limiting range of the receiver. Fig. 5 shows the test setup. With this arrangement, I was able to make measurements of sufficient accuracy to tune the filter and to gain a reasonable feel for how it worked.

Actual tuning proved unexpectedly easy. Adjust the threaded rod for maximum

output at the frequency desired. Results indicated that the response was similar to that shown in Fig. 6; I had a filter. But it wasn't sharp enough for my needs—I needed (or at least wanted) additional attenuation at the repeater's transmitter frequency, 600 kHz above the receiver's frequency. Something else was needed.

Let's go back to theory for a minute. At resonance, the inductive reactance is exactly equal to the capacitive reactance of the circuit and each cancels out the other; that's the very definition of resonance. At frequencies below resonance, the inductive reactance is smaller than the capacitive reactance; hence, the overall result is a circuit that looks like a capacitor. Above resonance, the reverse is true, and the circuit appears to be an inductor. Since my transmitter frequency was above the receiver (filter) frequency, the filter would look like a small inductor there. If I put a small value of capacitance in parallel with the filter, it should be possible to make it resonate with this apparent inductance, hopefully at the frequency of the (undesired) transmitter output. This would, in effect, form a parallel resonant trap in series with the receiver input, just as the traps in many multiband antennas are formed. The results should be similar.

I used a 2-15-pF air trimmer. By alternately tuning the threaded rod for maximum output at the receiver frequency and the trimmer for minimum output at the transmitter frequency, I was able to achieve results similar to those shown in Fig. 7. The peak of the response fell at the desired receiver input frequency, while the notch in the response curve fell at the transmitter output frequency. The difference between the two measured on the order of 16 to 18 dB and, because of suspected leakage around the cavity, is probably greater. Since some references claimed that the maximum rejection for such a cavity is about 20 dB, I wasn't doing too badly. I couldn't measure the insertion loss accurately, but it appears to be about 1.5 dB, which is entirely satisfactory and near the values quoted for commercially available cavities.



Detail showing top plate, coupling loops, and upper portion of tuning stub. Stub in this version was soldered to a threaded fitting which in turn was fastened in a hole in the top plate.

Subsequent investigation revealed that at the higher end of the tuning range, the Q appeared to be substantially higher, as evidenced by a sharper filter response. This is probably due to the fact that the distance between the center stub and the inside of the cavity is larger (in terms of a wavelength), so losses are reduced; also, the end of the stub is further from the bottom of the cavity, also reducing losses. If I were planning to build another of these filters, I would try the larger 2-pound coffee cans and use five rather than four of them.

It has been many months since I built this filter. Rechecking its tuning and response curve indicates no change, even though I live in a high humidity area and some corrosion was expected; apparently it is tight enough that this will be no problem. I have detected no noticeable shift in its parameters due to temperature excursions, although I have not subjected it to wide extremes.

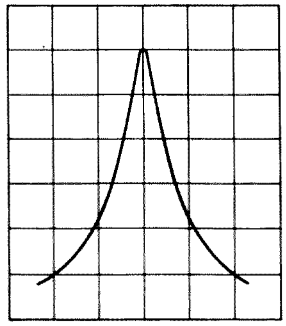


Fig. 6. Shape of the response curve of the cavity filter without shunt trimmer.

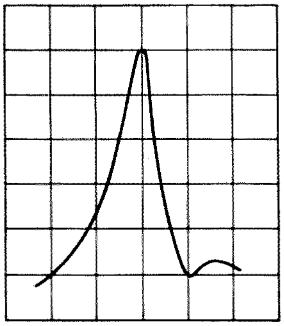

Fig. 7. Shape of the response curve of the cavity filter with shunt capacitor included.

The proof of the pudding is in the eating, they say, and the proof of this filter is in the system it was intended for. Without the filter, the very poor receiver I had responded to a 10-Watt signal anywhere in the two-meter band when the source was a few feet away from it; with the filter inserted between the antenna and receiver, an 80-Watt signal, at the same distance, has no effect until it is within about 30 kHz of the receiver frequency—the bandwidth of the filter included in the receiver's first i-f.

So what have we learned? It is possible, even easy, to make a cavity for your own use. It isn't expensive. Home tools and building techniques are more than adequate. Readily-available components can be used, and most dimensions are not at all critical. It is not difficult to tune up, and readily-available equipment can be used.

We don't have to pay a fortune for commercial cavity filters or duplexers for low-power use. While it may be advisable to do so for wide-coverage, heavily-used machines, we can quite easily use these for low-power, local-coverage machines. By substituting a small inductor for the trimmer capacitor, the notch can be moved to the low side of the response curve so several cavities can be connected together to form a duplexer; although adjusting the inductor would be more difficult than the trimmer, it can be done. Maybe now we can see more of these low-power, local-coverage machines, reducing the load on the wide-coverage systems. ■

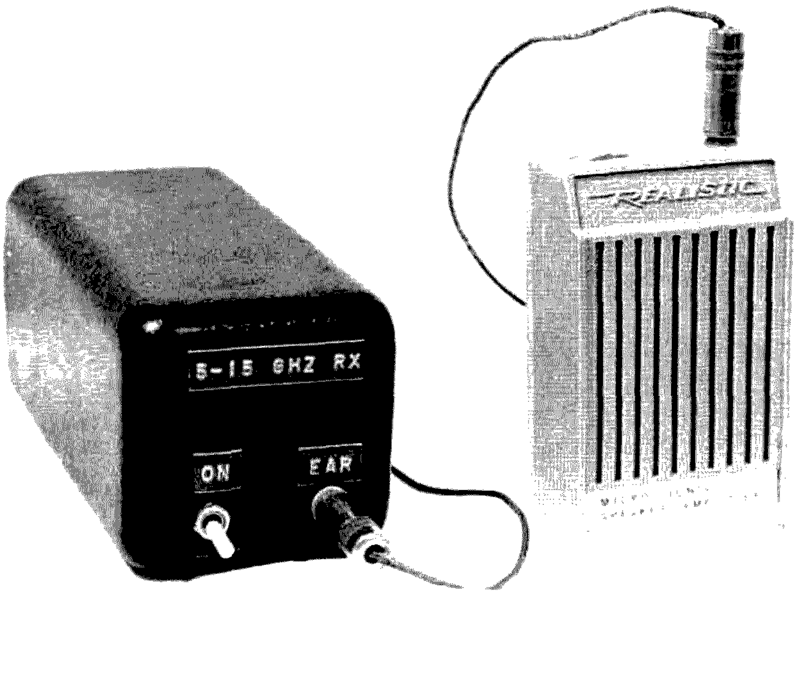
Push Your Radar Detector to the Limit

Without this simple modification, you won't know what you are missing—until it's too late.

The use of speed-detection radar devices by law-enforcement agencies as a means of enforcing speed-limit laws is becoming very controversial in the United States. A court in Miami, Florida (Dade County) already throws out radar speeding cases if there is no other data presented. The State of Kentucky has a court case pending to determine the validity of radar as a speed-law enforcement tool. If the courts later rule that radar cannot be used as a means of enforcing the speed laws of the country, radar sets will probably not be used by enforcement agencies. The auto radar detector thus would no longer have an operational requirement. What will you do with your radar detector which has accompanied you so faithfully in your auto all these past years?



The author's radar detector modified to receive signals from 5 to 15 GHz. Both receiver and audio amplifier operate off 9-volt batteries and are self-contained.

Extend Its Usefulness

Until such time that auto radar detectors become "useless," in the sense that they may not be needed to provide an alerting function for you, a simple modification to almost any detector will let you extend your use and interest in a radar detector. Before we go into how the simple modification works, let's review how the speed radar works so we will better understand our radar detection operation.

Law enforcement agencies use the familiar Doppler shift principle (named after Johann Doppler, 1803–1853) to determine the speed of a vehicle. A hand-held radar transmitter emits about 100 milliwatts of continuous microwave energy

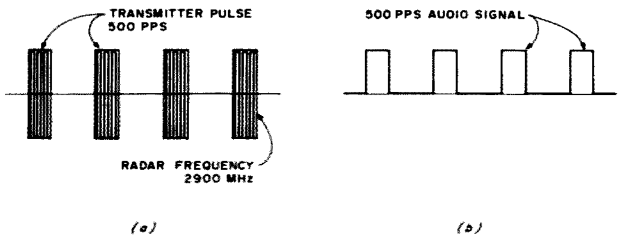


Fig. 1. Pulse radar signal (a) and audio signal (500 pps) when detected at a distance (b).

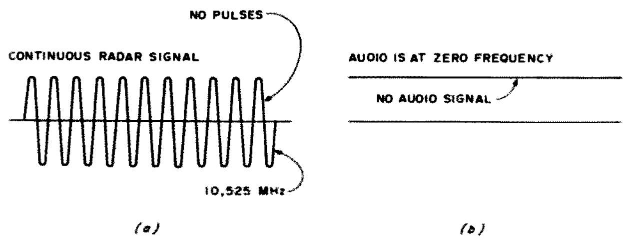

Fig. 2. Continuous-wave (CW) radar signal (a) produces no audio signal when detected at a distance (b).

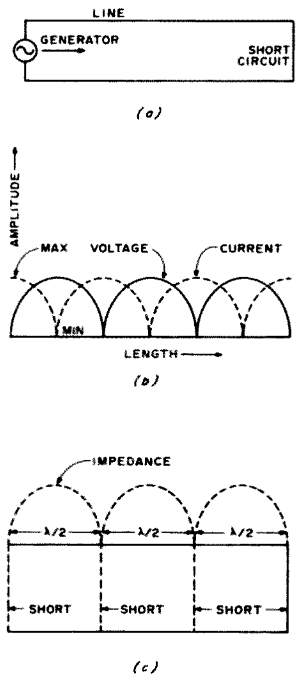

Fig. 3. Standing waves on a shorted transmission line. In (c) we see that a short is reflected every half wavelength.

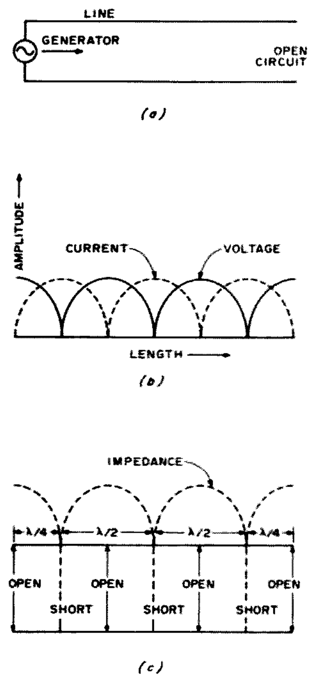

Fig. 4. Standing waves on an open transmission line. In (c) we see that an open is reflected every half wavelength.

at 10,525 MHz (X-band) or 24,100 MHz (K-band). The radar signal is concentrated in a narrow beam by a horn-type antenna so that the target vehicle is illuminated with the maximum amount of energy. Because of the movement of the vehicle, the 10,525-MHz signal is Doppler-shifted up in frequency about 940 Hz for an auto traveling at 60 mph. This upward Doppler shift is obtained for the emitter stationary (but vehicle moving) and is arrived at by the expression: Emitter stationary: $f_{D1} = f_1[(V + V_0)/V]$, where f_{D1} is the Doppler shift frequency in Hz, f_1 is the operating frequency (10,525 MHz), V is the velocity of light, and V_0 is the velocity of the vehicle in same units as V.

However, the transmitted signal must now be returned (reflected) to the radar receiver. So now the vehicle acts like a transmitter and originates (reflects) a signal (emitter moving) which also is Doppler-shifted up in frequency when it arrives at the radar receiver. The returning signal is shifted up in frequency according to the expression: Emitter moving (vehicle): $f_{D2} = f_2[V/(V - V_S)]$, where f_{D2} is the Doppler shift frequency in Hz, f_2 is the reflected frequency (vehicle)(10,525 MHz + f_D), V is the velocity of light, and V_S is the velocity of source (vehicle) in the same units as V.

We thus find that the total Doppler-shifted frequency is equal to $f_{D1} + f_{D2}$. For a vehicle traveling at 60 mph toward a radar, the total Doppler-shifted frequency is equal to 950 Hz + 950 Hz for a total shift of 1900 Hz. We arrive at this frequency after accounting for the original frequency of 10,525 MHz. This is about 31 Hz per mile for a radar operating at a frequency of 10,525 MHz. The total Doppler shift for a K-band radar would be about 2.3 times greater, or 72.5 Hz per mile.

The speed radar receiver must now process the Doppler-shifted frequency into miles per hour and then display and store it for record until the display is reset, awaiting another vehicle. The speed radar has to be triggered on for only a few seconds in order to lock on and obtain a good speed reading on a vehicle, although older units may be left on all the time. The time available to "hear" the radar transmitter, therefore, isn't very long.

How the Auto Radar Detector Works

Pulse Radar. Before the auto radar detector came along, there was only the radar speed detector. But with the advent of the auto-equipped radar detector, the *detector* became the *detectee*! (Or the *chaser* became the *chasee*.) And so the hunt has continued for about 30 years.

Old speed radar sets used the pulse principle as was used during World War II. Fig. 1 shows a series of radar pulses used to determine range to a target and the audio (500 pulses per second) produced by a diode detector receiver when listening to the radar. The rapid turning on and off of the radar carrier produces a music-like audio tone when the radar signal is detected and amplified.

Doppler Radar. Speed radar sets for the past 20 years or so have employed a continuous-wave transmitter, that is, one not modulated with any type of signal. It depends on the rapid Doppler shift in frequency (up in frequency when approaching and down when receding) to produce a shift in frequency which can be equated to *velocity* of a target rather than *distance* to a target as in the pulse-radar case. However, as we see in Fig. 2, the continuous carrier signal does not produce an audible signal when you detect and *listen* to it. Since there is no modulation on the signal at the transmitting end, we must do something to it at the receiving end so that we can detect its presence. And, of course, we must do this as inexpensively as possible as many consumer units will be bought.

Chopping the Radar Signal. You have no doubt driven or walked down a tree-studded roadway when the

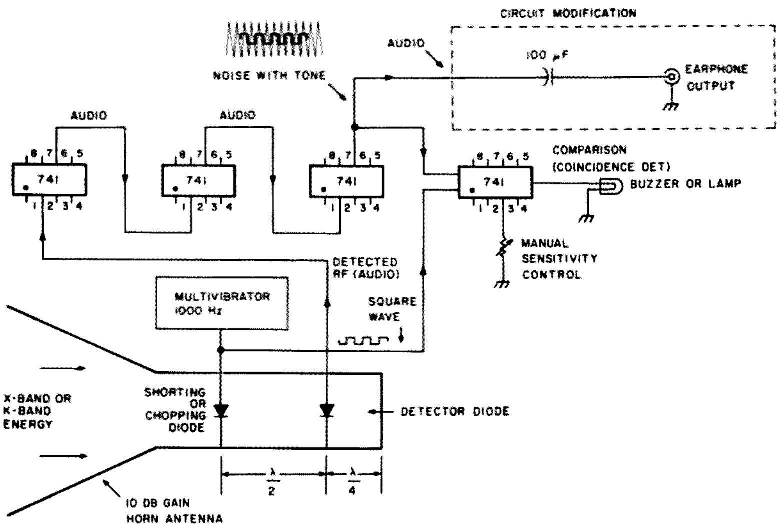

Fig. 5. Auto radar detector diagram showing chopping diode, detector diode, audio amplifiers, comparison circuit, and alerting buzzer or sounder.

sun is shining brightly. As you move along, bursts of sunshine are seen to stream through the foliage between patches of shadows. We are observing the modulation of the sun's steady rays of light where they are rapidly "turned on and off" by the foliage. In much the same manner, we will interrupt, or chop, the radar signal we receive so that we can process it to turn on an audio-altering device or a visual indicator.

In order to fully appreciate the uniqueness of the technique used to "chop" the radar signal, let's take a look at some fundamentals as they relate to antenna transmission lines.

The Shorted Transmission Line. When you take a transmission line such as an open-wire line or coax line as used in your amateur radio or CB mobile installation and short it at the antenna end, you will have zero volts across the end (as shown in Fig. 3). We see a generator sending a signal down the lines with a short at the right-hand end (a). In (b) we see that on a line terminated in a short, the voltage is zero at the end and maximum one-quarter wavelength back from the end. We see, also, that the short is repeated every half wave at the operating frequency (c). No voltage exists at the short, although the current is maximum. This can be likened to placing a screwdriver (zero Ohms) across an ac outlet of 115 volts. There will be a lot of current flowing till the fuse blows or the circuit breaker trips out, but there won't be any voltage! (Don't try this at home!)

The Open Transmission Line. Now let's look at an open terminated transmission line. In Fig. 4, we see a generator driving a signal down the line (a). In (b) we see that there is maximum voltage at the open end of the line and every half wave back toward the generator. In (c) we also see that the open circuit becomes a short circuit just one-fourth wavelength back from the open end.

What we have here is a means of chopping the radar signal as it comes down the waveguide transmission line from the horn antenna used in most radar detectors. What we do is to cause a diode placed across the transmission line to act as an open and a short, alternately, at an audio rate between 1000 and 3000 times per second. When a diode conducts in the forward direction, it acts like a short circuit (very low resistance) but when it does not conduct, it acts as an open circuit (very high resistance).

The Radar Diode Detector. An abbreviated circuit and block diagram of my Snooper (Autotronics, Inc.) radar detector is shown in Fig. 5. The shorting, or chopping, diode is turned on and off by the multivibrator circuit which puts out a square-wave signal at an audio rate of 1000 to 3000 pulses per second. Note that when the shorting diode is conducting (anode positive), it acts as a short in the waveguide. A half wave away, a short is also reflected so that the detector diode is shorted. The detector diode is one-fourth wavelength away from the short in the end of the waveguide so that it always appears as an open, free to detect and rectify any microwave energy coming down the waveguide from the 10-dB gain horn antenna that is chopped up by the shorting diode.

The Comparison Circuit. The detected audio from the detector diode is amplified in several IC chips (type 741) and then routed to a comparison or coherent detector where it is compared to an audio signal arriving from the 1000-Hz multivibrator. A manual sensitivity control is used to set a level at which the audio alarm buzzer or lamp is turned on. The comparison circuit is activated when the signal arriving from the detected audio channel (outside signal) is stronger than the signal from the multivibrator (inside signal). This means a radar signal is being received and the alarm is activated.

The Case of the False Alarm. There are a number of signals, however, that can activate the detector, other than a real speed radar signal. We will look at the signals in greater detail further on, but let's examine what happens when you receive a signal. The first thing you do is to look for the speed radar vehicle. Not seeing one, but the audio alarm is still sounding off, you turn the manual sensitivity control down until the sounder stops. However, what you have done is to make your detector less sensitive to outside signals. You are now very likely to get "pinged" by a real speed radar and not know it (till the bubble machine starts!).

Modify Your Detector to Receive Other Signals. What we will do at this time is to make a slight modification to your detector—to add an audio output capability. We then run this audio output to a small self-contained packaged audio amplifier so that we can listen to *all* signals that are detected by your receiver. We will let your ear become trained so that it can tell the difference between a pulse radar from an airplane, an airport radar, a strong TV station, or a real bubble-machine emitter!

Referring to Fig. 5, we see a dotted area which shows the added circuitry to provide the audio output capability. Any battery-operated audio amplifier will do the job, and one readily-available is the speaker/amplifier from Radio Shack No. 277-1008 for under $12.00. The

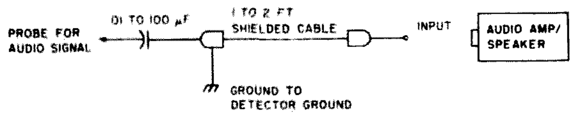

Fig. 6. Arrangement to probe for detector audio circuit. A hiss shows you have located a suitable point to connect the audio output.

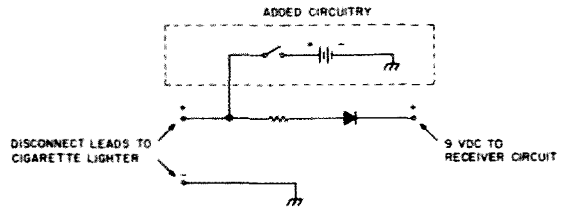

Fig. 7. Radar receiver modified to operate off a 9-volt battery for hand-carry operation.

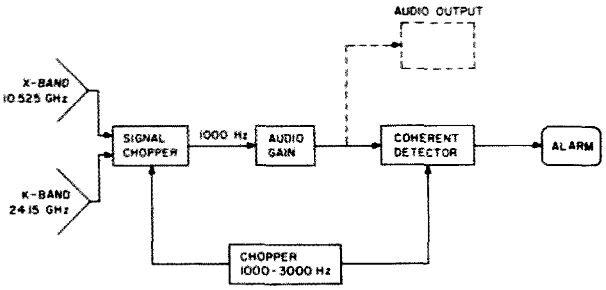

Fig. 8. Block diagram of typical X- and K-band radar detectors. Audio output modification covers both hands.

photo shows my Snooper detector modified for earphone output and an audio amplifier connected by a short piece of shielded audio cable which has male miniature audio connectors on each end.

In order to locate a circuit connection point in your detector which has sufficient audio voltage to drive the amplifier, use the arrangement shown in Fig. 6. Remove your detector from its housing, and with power applied to both units, probe the circuit board near where the manual sensitivity control is wired. There will be several points in the circuit where you will hear white noise, or hiss. This tells you that you have located an audio tone present of 1000 to 3000 Hz. This is the chopping or switching rate that you are hearing and it tells you that the unit is operating properly. When you shut off the radar detector (but leave the audio amplifier on), you may hear the tone become very clear as the white noise disappears before the switching tone. This may not occur in all modified units.

I have added a 9-volt transistor battery and switch to the detector/receiver so that the unit is entirely self-contained and can be hand-carried anyplace. It can be used on aircraft, boats, bicycles, and the like. Connect the battery to the same circuit point as the auto cigarette lighter as shown in Fig. 7. A battery will operate the radar receiver for a number of months with several hours use each day.

Connect the audio circuit as shown in Fig. 5 using a capacitor of 0.01 to 100 μF. To help you make the simple modification to your detector, ask a radio amateur or CB repair shop for assistance. You need not alter the appearance of your detector if you run a pair of small size wires outside your unit where the audio pair can connect to the amplifier.

Radio Signals You Can Receive

Now that you have modified your radar detector, you will be able to receive other radio signals. So that you will now know *what* signals you are receiving, leave your unit operating at its maximum sensitivity while you *ignore* those signals, keeping an alert ear open for the pure tone of a speed radar as it grows slowly out of the noise level. Remember, your detector is a fairly inexpensive device which is called upon to do a rather scientific task—receiving weak continuous-wave radar signals. As such, it is also subject to receiving and detecting any radio energy which is able to enter its detection circuits. You will use your ear to reduce the false alarm rate, and at the same time greatly increase your interest in your electronic surroundings. Let's look at some of the radar signals you may receive on your converted radar detector.

Speed Radar. Two bands are authorized by the FCC: X-band—10.525 GHz (10.5-10.55 GHz), and K-band—24.15 GHz (24.05-24.15 GHz). Power output—100 milliwatts (times antenna gain).

Stationary hand-held units are usually detected at about a half-mile away. If the transmitting unit is on continuously, you will hear the signal begin weakly as a pure tone of 1000 Hz or so, growing out of the white noise hiss. This hiss will not disturb you as it will be masked by road and car noise. But when that pure tone-signal jumps up at you, you'll know you have a live one! Remember—the signal you hear out of your detector (1000 Hz or so) is the switching frequency of the chopping diode. It has nothing to do with any Doppler frequency shift associated with vehicle velocity. You will hear the signal with both vehicles stationary if the radar is transmitting. The longest distance over which I have detected signals, over several hills and dales, is 8 miles. But you must be line-of-sight to the radar to hear him and hope he "pings" someone else so you will be able to hear him.

My modified Snooper covers only the X-band, so you may be pinged on K-band and not know it unless your unit has both X- and K-bands. There is presently little operation in K-band, but its use is increasing. In Fig. 8 we see the block diagram of typical X- and K-band detectors, with one modification covering both bands since there is a common audio channel.

Many law-enforcement vehicles will drive around with the radar switched on and transmitting all the time. The hand-held unit, aimed like a spot light, is temporarily placed face down on the front passenger seat. However, enough radio energy is scattered out of the vehicle so that you can detect it several blocks away, be it moving or stationary. You will also be able to detect a radar vehicle passing in the opposite lane of a divided highway from several blocks away. When you receive these signals on your receiver, you will know that you have achieved a good sensitivity level as the radar unit does not have its antenna beam aimed out of the car.

Aircraft Radar. These radars operate in the range of 9300-9500 MHz and usually are heard during inclement weather when the radar is used to navigate around bad weather. You'll hear a "zip-zip" as the airborne antenna sweeps back and forth. You'll be able to track it for many miles as you aim your

detector in azimuth and in elevation to the aircarft. Remember, these are pulse radars with high-power output and you can hear them for about ten miles from your location.

Ship and Coastal Radar. These radars operate in the 2900–3100-, 5350–5650-, and 9300–9500-MHz bands. Rotate your detector around slowly as you look for them near the coast as they will have an antenna rotation rate of 5–10 rpm. Large ships will move slowly as you track them while small vessels will move more rapidly and you may soon lose them. While driving along, you'll hear them for 5 to 10 miles before they fade out.

Weather Radar. These radars operate around the clock from a number of locations in the country as part of the NOAA weather service, in a band of frequencies from 2900-3100 MHz. These signals are heard on occasion from as far away as 40 miles when the sky is filled with clouds of rain or heavy moisture. The radars have a low antenna-rotation rate as well as a low pulse-recurrence frequency (prf) which sounds like "burt, burt." On occasion, you may find these signals being reflected off large thunder clouds that are 10 to 20 miles away.

Microwave Communications. These signals will fool you the most as they sound like a real Doppler (continuous-wave) radar. As you drive around in the city or country, you may pass into their beam and hear the pure tone increase in intensity. You'll look around for a bubble-machine car but not see anything. Then, as you drive further, the signal may disappear as you get closer to, and pass under, the beam from the antenna (probably a 3′ to 5′ dish) mounted on the side of a building or on a tower.

These signals usually lie in the frequency range of 12.985-13 GHz. Other users might lie in the 7-9-GHz band. These systems usually operate with just a few Watts of power to the antenna but with a high-gain beam. Once you locate the position of such a signal, you can use it to check the proper operation of your receiver each time you drive by. In the event a real Doppler radar were to begin operation in that same area, your trained ear will still be able to discern a difference between the two.

CB Transmitters and Mobile Radiotelephones. On occasion, you will hear a brief whistle of a signal as you pass other vehicles on the highway. The signal might last for just a few seconds and you'll think you've been pinged. What you have done is pass very close to a CB or mobile radiotelephone in operation. If you glance quickly at the passing autos, you may observe someone talking into a telephone handset. These transmitters usually operate in the 150-170-MHz or 450-MHz range and you are hearing a harmonic due to the closeness of your receiver to them.

Television Stations. Depending upon the TV channels in your location, you may or may not hear false alarms. UHF stations which operate on channels 14-83 (470-890 MHz) at power levels up to 1 million Watts may be received up to 20 miles away, causing you to turn down your manual sensitivity to quiet the alarm. While driving in a strange city, you'll need the discerning power of your ears to tell you what sounds are a TV channel and what sounds are the pure tone of your friendly gendarme radar. These TV signals are so strong that they plainly drive through the X-band antenna and are detected (chopped) and you hear them as real "fake" signals.

Aircraft Runway Landing Aids. As you drive by or near some airports, you may hear all sorts of signals being picked up by your 5-15-GHz receiver. Some of the approach-control radars are at 2800 MHz and you'll hear their prf buzz each time the antenna rotates by your auto as you drive by. You may also hear reflections off buildings by aiming your receiver antenna at the buildings. You may also hear sidelobes from the radar as it sweeps in azimuth.

One very interesting airport radar operates at a frequency of 9080 MHz with prf of 5500 Hz as it sweeps in azimuth and elevation, looking down the runway at approaching aircraft. As you drive by, you will hear its signal. It goes "cheep, cheep" as it scans its pattern across your vehicle. You might hear this one as far as three miles from the end of the runway.

Other Signals You May Receive. There are now a number of microwave burglar alarm systems that operate throughout the country at X-band. As a consequence, depending on the sensitivity of your receiver, you may detect them when driving in residential areas, shopping centers, and industrial areas. Again, you will be able to recognize their sound and identify the area of the city where you receive them.

Other Receiving Considerations

Inverse Square Law ($1/R^2$). A radio signal undergoes a loss as it propagates through space; this is called the inverse square law. Double the distance, and the power received is one-fourth strength. For the radar receiver case, the signal suffers a $1/R^2$ power loss in reaching the target and a $1/R^2$ loss in the signal returning from the target to the radar receiver. For the radar case, therefore, the total power loss is figured by $1/R^4$. However, for the radar detector case, the power loss is only $1/R^2$, not $1/R^4$, as it does not have to look at reflected (bounced) radar energy. Thus, the *detector* can see the *detectee* twice as far away. All things being equal, you should hear him at twice the distance that he can see you. That provides a beep to the wise.

X-Band Radars. There are over 70,000 speed radar sets in operation in the US—about 95% in X-band.

K-Band Radars. About 5% of the radars operate in this band, and this number is increasing as equipment-design technology for this band improves.

Radar Detectors. It is estimated by manufacturers that there are approximately 2 million radar detectors in use in the US. Their use probably will increase as federal laws are enforced additionally by state authorities.

The Superheterodyne Radar Detector. The superheterodyne receiver is the best type of circuit that you can buy. They are just now becoming available in quantity on the radar-detector market and range in price from about $150 to $300. The circuit is the same as that employed in most AM, FM, and TV receivers and is very selective in frequency. Because of this feature, the receiver is able to reject almost all the signals that can be found in the outside world of the present-day radar speed detectors.

Use of the 5-15-GHz Receivers. The modified receiver you are using covers about 5-15 GHz. You'll hear many different kinds of signals in this frequency band, some of interest, some of no interest, and some a bother. Whatever the reason for you to use it, remember—the FCC under Title 47 of the Communications Act of 1934 states that no radio receiver can be licensed, restricted, or banned. And that includes any government agency or state. Happy listening! ■

Personalize the M800 RTTY Program

Now you can design and save your own version of this popular software package. All it takes is a POKE or two.

Since the introduction of the low-priced microcomputer for the home market, radio amateurs have quickly taken advantage of the fact to modernize their ham shacks. These individuals very quickly realized that not only was the machine capable of doing housekeeping chores, but also it could be used on the air. The first software for the TRS-80's use on CW and RTTY was the Macrotronics M80 written by Dr. Ron Lodewick N6EE. This program was a fantastic learning experience for all users and the enthusiasm generated was sufficient to convince Ron to create the M800. As the FCC opened the door for the use of ASCII in the USA, shortcomings were found in that portion of the program. It was not long at all before Ron issued FREE a corrected version called the M800 1.1.

Now come the shortcomings of any software that is mass-produced. Being mass-produced, one must organize the program to suit his or her operating circumstances. I do not fault Macrotronics for this because to maintain a viable operation, one soon has to lose the personal touch. If the software was to be constructed tailor-made for the individual, the cost would be astronomical, as you can well appreciate.

To get started, simply load and run the M800 as usual (make sure you have the hardware turned on). Once you have entered your name and callsign, you can proceed to set the program as you would for operating, such as CW shift, ignore returns, fast diddle, etc. Now that you are satisfied, run through the operating steps until you are sure you have it the way you want. Proceed to program the three message memories and try them out as well just to be sure that they function correctly. Once satisfied, go to the receive mode and enter the name of the station that you work most often. This is an added touch that saves time.

Now that the program is running properly, break the out by resetting (don't forget to use the break key if you have the expansion interface) and POKE the number of diddles and lines of CQ, RY, and QBF. You can now load TBUGHI and punch a new tape with the P command as follows:

P 43FO 6652 4575 M800 <ENTER>

This will give you a permanent copy. It would be advisable to make a few backups prior to trying out the tape as TBUG does not verify. I have made several different copies, for normal operating, contesting, DXing, and other operations.

The information that I have to pass on to you is very simple and should make the software a dream to use. The program will come up running in the receive mode with all of your information stored as an integral part of the program. The only other software that you require to accomplish the task is TBUG, but this must be relocated out of the way of the M800. If you have trouble with the relocation, an excellent article is available in *80 Microcomputing*, issue #1, January, 1980, page 118.

Disk users will also benefit as the program can be auto-loaded. Using the Apparat 40 Track Newdos+, it takes less than five seconds to receive. Also using Newdos SUPERZAP, you can change the CQ, RY, and QBF messages to suit the operation. I have changed the CQ message from

CQ CQ CQ CQ CQ CQ CQ CQ CQ CQ CQ CQ CQ CQ CQ CQ CQ CQ CQ

to

CQ TEST CQ TEST CQ TEST DE VE4AFO CQ TEST CQ TEST CQ TEST DE VE4AFO.

This is only a simple example of program manipulation; you are limited only by your own imagination.

An added feature is one that should make people very happy: The troublesome keybounce can be overcome using the utility DBNC found in *80 Microcomputing*, issue #1, January, 1980. If you have more than 16K, it is very simple to relocate by changing the ORG statement.

I hope this will help your operating; your comments would be appreciated. Special thanks go to my father, Jim Bowman, and to Bert Anderson VE4AP. Without their help, this article would not have been possible. ■

HAM HELP

I need an audio frequency counter which will work with a Swan 350. I am blind and need some way of determining the exact frequency I am working.

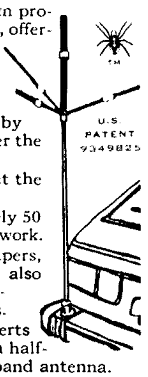
The Spider™ Antenna

The modern multi-band mobile antenna —switch to 10, 15, 20 or 40 meters without stopping to change resonators.

Features of the Spider™ Antenna



- The Spider™ Antenna is less than six feet high and the longest resonator projects out from the mast 24 inches. This gives a slim profile, low height and light weight, offering little wind resistance and eliminating the need for a spring mount.
- Each resonator is tuned to the desired portion of the band by a tuning sleeve which slides over the outside of the resonator.
- SWR is approximaterly 1:1 at the selected resonant frequency.
- Base impedance approximately 50 ohms, requiring no matching network.
- Ideal for use on vans, campers, motor homes, travel trailers; also in mobile home parks, apartment houses and condominiums.

The Spider™ Adapter converts any mono-band antenna with a half-inch-mast into a modern four-band antenna.

The Spider™ Maritimer™ is the ultimate for marine use. Made of non-magnetic stainless steel and nickel-chrome plated bronze, using regular Spider™ resonators and tuning sleeves.

Accessories—Bumper, ball, angle and stud mounts. Quick disconnects. RG-58A/U coaxial cable and connectors. Ground radial systems. Copper foil and copper braid ground straps.

MORRIS PLAINS NJ
MAR 4

The Split Rock Amateur Radio Association will hold its sixth annual electronics auction on Friday, March 4, 1983, at VFW Post #3401, State Route 53, Morris Plains NJ. The Morris Plains VFW hall is located a short distance from US 202 and NJ 10 and is easily reached via I-80, I-287, and US 46. Admission is $1.00. Doors will open at 7:00 pm for unloading and inspecting equipment and the auction will commence at 8:00 pm sharp. Items to be sold must be working equipment and loose parts must be bagged in the largest quantity possible. A commission of 10% will be taken on the first $50.00 of each sale. Commissions are payable in cash only. Refreshments will be available. Talk-in on 146.385/146.985 (WR2ADB) and 146.52. For more information, please write to SARA, PO Box 3, Whippany NJ 07981.

OLD BRIDGE NJ
MAR 6

Atco NJ 08004

QCWA QSO PARTY—PHONE

Starts: 0001 GMT March 12
Ends: 2000 GMT March 13

This is the second part of the 26th annual QCWA QSO party. You can work the same station more than once providing it is on another band. Only the bands listed under frequencies will count in this QSO party.

EXCHANGE:

QSO number, operator's first name, QCWA chapter identification (official number or name), and state or country. Members not affiliated with a chapter should use "AL."

FREQUENCIES:

Any authorized amateur frequency in the bands that are listed below is permissible. The following suggested frequencies have been selected to minimize interference to others; however, please feel free to wander up or down from these if you so desire: 3900-3930, 7230-7260, 14280-14310, 21350-21380, 28600-28630. These frequencies are selected as a starting place. When pileups occur, don't be afraid to go either side of these frequencies.

SCORING:

Each contact made with another QCWA member will count as a single point. This year's contest has three multipliers: chapters, states, and countries. For each band, every new chapter is a multiplier of one, every new state (USA) is a multiplier of one, and every new country (ARRL DXCC list) is a multiplier of two. At the end of the party, add up your total contacts for all bands and multiply it by the sum of all your multipliers for all bands. This will give you your total and final score.

ENTRIES:

Please keep separate logs for each band. Logs should include the following information: time (GMT), call, QSO numbers, name, chapter number or name, and state or country. It is the responsibility of each contestant to provide a legible log, no carbon copies, and to list all claimed contacts. The total contacts and multipliers for each page should be recorded at the bottom of each page. The total contacts for the party will not be returned. Make sure you have correct postage when you mail your logs. Send logs no later than March 31st to: Spaceport Center #66, Donald McClenon N4IN, 3075 Florida Avenue, Melbourne FL 32901. Separate logs and scores must be submitted for both the CW and phone parties.

YL ISSB QSO PARTY—CW

Starts: 0001 GMT March 12
Ends: 2359 GMT March 13

Two six-hour rest periods are required. Operating categories include: single operator, DX/WK partners, and YL/OM teams. All bands will be used and the same station may be contacted on different bands for contact points but not as country multipliers. VHF and UHF may be used but all contacts must be direct and not through repeaters. Nets are not allowed!

EXCHANGE:

Name, RST, SSB number, country, W/K state or VE province, and DX/WK partner's call. If no partner, leave blank. If nonmember, send "no number."

FREQUENCIES:

On HF, use the USA General-class band portions. Check 80 and 40 meters on the hour.

SCORING:

Score 3 points for each member contacted on own continent, 6 points if different continent. Nonmember contacts count *one* point. Only member station contacts count for multipliers. Multipliers are each state, country, and VE province; also, each team contacted but only once for each team. When DX/WK partners contact each other, it counts as a double multiplier. If your total dc input power is 250 Watts or less during the entire QSO party, then count an additional power multiplier of *two*. Final score is sum of QSO points times the total multiplier.

AWARDS:

Special certificates will be awarded to the winners of each category. Regular certificates for country, US state, and Canadian province winners.

ENTRIES:

Logs must show date/time (GMT); station contacted; RST; mode; band; SSB number; US state, VE province, or country; and period of rest time. Summary sheets show states, Canadian provinces, countries, YL/OM teams, and DX/WK teams and partner contacts. Send logs and summary sheets to: Rick & Minnie Connolly (K0RDJ & KA0ALX), Star Rt. 1, Crocker MO 65452 prior to June 1st. Be sure to indicate who your DX/WK partner is!

WORKED ALL MORTON CONTEST

0001 GMT March 12 to
2400 GMT March 13

Morton stations will be working all bands, phone and CW, about 5 kHz apart up from the bottom edge of the General portion of each band. Contest exchange consists of RS(T) and state, province, or country. Certificates will be issued to those hams who have QSOs with five or more members of the Morton Amateur Radio Club or residents of Morton, Illinois during the contest period. To receive the award, applicants should send log information listing at least five Morton contacts along with a large SASE to: WD9AEU, 701 Columbus Ave., Morton IL 61550.

IDAHO QSO PARTY

Starts: 0000 GMT March 12
Ends: 2359 GMT March 14

Sponsored by the Kootenai Amateur Radio Society of northern Idaho.

EXCHANGE:

RS(T) and Idaho county, state, province, or country.

FREQUENCIES:

SSB—3920, 7260, 14250, 14325, 21325, 21380, 28550.

CW—50 kHz up from the lower band edge.

Novices—25 kHz up from their lower band. No net frequencies, please!

SCORING:

Idaho stations score 1 point for each QSO and multiply by the number of Idaho counties, states, VE provinces, and countries worked. Others score 1 point per Idaho QSO and multiply by the total number of Idaho counties worked.

AWARDS:

Awards will be issued to the top scorer in each Idaho county, state, VE province, and country.

ENTRIES:

Mailing deadline for all entries in the USA is April 16th, May 1st for all DX coun-

THE OLD TIMER'S BULLETIN

OFFICIAL JOURNAL, ANTIQUE WIRELESS ASSOCIATION, INC.

Published for the Old Time Wireless Operator, Historian and Collector

NEWSLETTER OF THE MONTH

Galena crystals, horn speakers, and 4-pillar tubes are all subjects you would not expect to find in a modern amateur publication—unless it happened to be the *Old Timer's Bulletin*, this month's winner in *73*'s newsletter contest.

The *Bulletin* is published by the Antique Wireless Association, which is devoted to the research and documentation of the early history of wireless communications.

What differentiates this bulletin from many others is the relatively little space devoted to organizational news; instead, the *Bulletin* contains a variety of construction articles, historical shorts, and sage antique-radio restoration advice.

The December, 1982, issue included construction plans for a 1928-vintage transmitter using two UX-210 tubes and the design parameters for Atwater Kent horn speakers. Another article, "Arthur Wehnelt and His Wonderful Cathode," looked at the contributions of this little known physicist, while contributor Alan Douglas pulled Raytheon's 4-pillar tubes out of the cobwebs.

Special sections include columns for antique-radio collectors, a section on home-brewing parts, and tips on restoring old radios.

The *Bulletin* is spiced with reprints of news articles and cartoons from early in the century, and the artwork throughout meshes with the publication's focus on that era. Reading it, you could almost imagine that you were back in the days of the spark gap.

The *Bulletin* is typeset and printed, with good-quality black and white photographs throughout. Even those who do not remember the days when the tube was king can enjoy reading about the early progress of electronics and probably learn a thing or two in the process.

Congratulations to the Antique Wireless Association for making the good old days alive and interesting.

If your club would like to enter *73*'s newsletter contest, send a copy to: Editorial Offices, *73*, Peterborough NH 03458.

tries and Canada. Send entries to: Vladimir J. Kalina KN7K, South 1555 Signal Point Road, Post Falls ID 83854.

VIRGINIA QSO PARTY

Starts: 1800 GMT March 12
Ends: 0200 GMT March 14

The 1983 QSO party is again sponsored by the Sterling Park Amateur Radio Club of Sterling Park, Virginia. The same station may be worked on each band and each mode. Virginia stations may contact in-state stations for QSO and multiplier credit. Virginia mobile stations may be worked in each new county they operate from for new QSO and multiplier credit regardless of whether or not previously worked on the same band and mode in another county. QRP stations must run 5 Watts or less for their entire operating time.

EXCHANGE:

QSO number starting with 001 and QTH consisting of state, province, DX country, or Virginia county. Virginia stations note that the reference for valid counties is *CQ's Counties Award Record Book* which lists a total of 95 countries.

FREQUENCIES:

Phone—3930, 7230, 14285, 21375, 28575, and anywhere on 160-meter band except in DX windows for US stations.

CW—60 kHz up from the low end of each HF band except anywhere in 10- and 160-meter bands or Novice subbands.

SCORING:

Count one point per QSO. Virginia stations multiply total QSOs by the sum of states, Canadian provinces, DX countries, and Virginia counties worked. Others multiply QSOs by the number of Virginia counties worked.

AWARDS:

Engraved plaques to the top scoring stations in the following categories: high Virginia single operator (fixed location), sponsored by K3RZR and KA3DTE; high Virginia mobile station donated by Electronic Equipment Bank of Vienna, Virginia; high out-of-state (including DX) station; high QRP station (if 5 or more QRP entries are received) donated by K7HMP.

ENTRIES:

Follow ARRL standard contest guidelines for logs. Indicate each new multiplier as worked. Send a summary sheet, with your log and an SASE for a copy of the results, to: Virginia QSO Party, c/o Barry Pybas KW4I, 313 W. Derby Avenue, Sterling Park VA 22170. Mailing deadline is April 15th.

WISCONSIN QSO PARTY

1700 TO 2400 GMT March 13

Use both CW and phone, stations may be worked once per mode on each band. Mobiles may be worked again when changing counties. No repeater QSOs!

EXCHANGE:

RS(T) and state, province, or Wisconsin county.

FREQUENCIES:

Phone—3990, 7290, 14290.
CW—3560, 7050, 14060.

SCORING:

Phone contacts count 1 QSO point while CW contacts count 2 QSO points. Wisconsin stations multiply QSO points by total number of states, provinces, and Wisconsin counties. DX countries count for QSO points but not multipliers. Non-Wisconsin stations multiply QSO points by number of Wisconsin counties (72 max). As a bonus, Wisconsin mobiles add 500 bonus points for each county that you operate from outside your home county with a minimum of 15 QSOs per county to qualify.

AWARDS:

Awards will be presented to the highest scores in each state and province, as well as to the highest aggregate club score.

ENTRIES:

All entries must contain a log consisting of: time in GMT, call, RS(T), state, Wisconsin county, mode, and a score summary. Logs containing more than 100 QSOs must be accompanied by a dupe sheet. Entries must be postmarked by April 15th and sent to: Wisconsin QSO Party, c/o West Allis Radio Amateur Club, PO Box 1072, Milwaukee WI 53201.

BERMUDA AMATEUR RADIO CONTEST

Starts: 0001 GMT March 19
Ends: 2400 GMT March 20

The Bermuda Amateur Radio Contest, in its 25th year, is again sponsored by the Radio Society of Bermuda. The contest *is* open to all licensed amateurs in Canada, the USA, the United Kingdom, and the Federal Republic of Germany. Of the 48-hour contest period, your total operating time cannot exceed 36 hours with off periods clearly logged. Each off period must not be less than three consecutive hours. All stations must be single operator only and must be operating from their own private residence or property. Use all bands, 80 through 10 meters. No crossband or crossmode contacts are permitted. Additionally, no phone contacts are allowed between W and G or West Germany on 40 meters.

EXCHANGE:

All stations will send RS(T) reports and give the following: Canadians add province, UK stations add county, US stations add state, West German stations add DOK number, and Bermuda stations add parish. US and Canadian stations may exchange reports with West German, UK, and Bermuda stations only. UK and West German stations may exchange reports with US, Canadian, and Bermuda stations only.

SCORING:

Each completed contact, on each band, counts 5 points. Only one contact per station on each band regardless of mode. For all stations outside Bermuda, the multiplier is the total number of VP9s worked on each band. For Bermuda stations, the multiplier is the total number of states, provinces, counties, and DOK numbers for West Germany worked on each band.

AWARDS:

Printed awards to the top scorer in each state, province, county, and DOK area in West Germany. The top scorer in Canada, US, UK, and West Germany shall receive a trophy to be awarded at the Society's annual dinner held in October of each year. Round trip air transportation plus accommodation will be provided to overseas winners to enable them to receive their awards. Top winners for the 1979 through 1982 contests shall be eligible for the area awards only.

ENTRIES:

Logs must show all dates and times in GMT. A separate sheet must be used for each band. All contestants to compute their own scores and check for duplicate contacts. Dupe sheets must be submitted with logs to cover each band where more than 200 contacts are logged. For every duplicate contact for which points are claimed, a penalty of three contacts will be deducted by the contest committee. An excess of claimed duplicates may mean disqualification. No penalty will be exacted against duplicates for which no points are claimed. Each page must be clearly numbered and marked with contestant's call, year, and band to which it refers. All contestants must sign a statement that they have complied with the rules and terms of their license. All logs must be received by the Contest Committee, Radio Society of Bermuda, Box 275, Hamilton 5, Bermuda, not later than May 31st. Overseas contestants are recommended to forward their logs via airmail. All decisions of the contest committee are final.

Bermuda parish abbreviations are as follows: SAN—Sandys, PEM—Pembroke, SOU—Southampton, HAM—Hamilton, STG—St. George, DEV—Devonshire, WAR—Warwick, SMI—Smiths, PAG—Paget.

TENNESSEE QSO PARTY

2100 GMT March 19 to 0500 GMT March 20, 1400 to 2200 GMT March 20

This is the 13th annual QSO party sponsored by the Tennessee Council of Amateur Radio Clubs. You may work the same station on different bands, modes, or counties. Repeater contacts are not allowed. Mobiles compete against mobiles, portables against portables. Single-transmitter entries only. No county line operations allowed for multiple contacts. Portable stations must set up per field-day rules. No "list" operations are allowed. No CW contacts in phone bands.

EXCHANGE:

Signal report and state, province, country, or Tennessee county.

SCORING:

Score one point per phone QSO; 1.5 points per CW QSO. Combine phone and CW scores as one contest. Recognition will be given for phone or CW only scores. Tennessee stations multiply QSO points by sum of number of different states, Tennessee counties, and VE/VO provinces. All others multiply QSO points by the number of different Tennessee counties worked (95 max). For each portable or mobile station working outside their home Tennessee county, score 500 bonus points for each county outside of home county with a minimum of 10 QSOs.

FREQUENCIES:

Phone—1860, 3980, 7280, 14280, 21380, 28580.

Novice—3725, 7125, 21125, 28125.

CW—1815 and approximately 50 kHz up from bottom of each band. Note, you must log a minimum operating time of 10 minutes for each change of band or mode.

AWARDS:

Plaque to highest scoring Tennessee fixed, Tennessee mobile and portable, plus out-of-state fixed. First place certificates to highest scoring station in each state, Canada, DX country, Tennessee Novice/Technician, out-of-state Novice/Technician, Tennessee phone only, and Tennessee CW only. Participation certificates to every station sending in logs with at least 15 contacts.

ENTRIES:

Logs must show date/time in GMT, station worked, band, mode, exchange, and score. Submit a cross-check sheet similar to ARRL CD77 for each band and mode with 100 or more contacts. Logs must be legible to avoid disqualification. Logs must be postmarked by May 1st and sent to: Oak Ridge ARC, Attn: Contest Coordinator, PO Box 291, Oak Ridge TN 37830. Please include a business-size addressed envelope with your logs.

BARTG SPRING RTTY CONTEST

Starts: 0200 GMT March 19
Ends: 0200 GMT March 21

The total contest period is 48 hours, but not more than 30 hours of operation is permitted. Time spent listening counts as operating time. The 18 hours of nonoperating time can be taken at any time during the contest, but off periods may not be less than 3 hours at a time. Times on the air must be summarized on the summary sheet.

There are separate categories for single-operator, multi-operator, and shortwave-listener stations. Use all amateur bands from 80 through 10 meters. Stations may not be contacted more than once on any one band.

EXCHANGE:

The message exchange consists of: 1) Time in GMT; this must consist of a full four-figure group, and the use of the expression "same" or "same as yours" will not be acceptable. 2) RST and message number; the message must consist of a three-figure group starting with 001 for the *first contact made.*

SCORING:

All 2-way RTTY contacts with other stations within one's own country are two points; outside your country are ten points. All stations can claim a bonus of 200 points for each country worked, including their own. Note that any one country may be counted again if worked on a different band, but continents are counted only once. The ARRL country list is used and, in addition, each W/K, VE/VO, and VK call area will be counted as a separate country. Final score is (sum of QSO points times the total number of countries worked) added to (the number of countries times 200 bonus points each times the number of continents).

Note, proof of contact will be required in cases where the station worked does not appear in any other contest log received, or the station worked does not submit a check log.

AWARDS:

Certificates will be awarded to the leading stations in each of the three classes, the top station in each continent, and the top station in each W/K, VE/VO, and VK area.

If a contestant manages to contact 25 or more different countries on 2-way RTTY during the contest, a claim may be made for the Quarter Century Award (QCA) issued by BARTG and for which a charge of $3.00 (USA) or 15 IRCs is made. Make your claim at the same time you send in your log. Holders of existing QCA awards should indicate and list any new countries to be added to their existing records. Make your claims at the same time that you send in your log. However, due to the high volume of work, it will not be possible to prepare and dispatch any new awards or update any existing awards until the final results of the contest have been evaluated and published.

Additionally, if any contestant manages to contact stations on 2-way RTTY on each of the six continents and the BARTG contest manager has received either a contest or check log from each of the six stations concerned, a claim may be made for the WAC Award issued by the *American RTTY Journal*. The necessary information will be sent to the *Journal* who will issue the WAC Award free of charge.

ENTRIES:

Use a separate sheet for each band and indicate all times on the air. Logs should contain: date/time in GMT; callsign of station worked; RST and message number sent; time, RST, and number received; and points claimed. Logs received from shortwave listeners *must* contain the callsign of the station heard and the report sent by that station to the station he is working. Incomplete loggings are not eligible for scoring. The summary sheet should show the full scoring, the times on the air and in the case of multi-operator stations, the names and callsigns of all operators involved with the operation of the station. All logs must be received by May 31st in order to qualify. Summary and log sheets are available from the contest manager at the address shown below. The judges decision will be final and no correspondence can be entered into, in respect of incorrect or late entries, and all logs submitted will remain the property of the British Amateur Radio Teleprinter Group. Send entries to: Ted Double G8CDW, 89 Linden Gardens, Enfield, Middlesex, England EN1 4DX.

SPRING VHF/UHF QSO PARTY

Starts: 2100 GMT March 26
Ends: 0400 GMT March 27

Sponsored by the Ramapo Mountain Amateur Radio Club, this year's rules for this VHF/UHF contest are similar to last year's rules and current ARRL contest rules. Operating classes are defined as follows: single operator—one person performs all transmitting, receiving, spotting, and logging functions; multi-operator—those obtaining any form of assistance, such as the use of relief operators, loggers, or spotting nets.

EXCHANGE:

Each 2-way QSO must include an exchange of station callsign and section designator.

SCORING:

The grid-square and range scoring system has been retained, based on proven results obtained from the 1982 ARRL UHF contest. Each section is a geographical area one degree in longitude by one degree in latitude, identified by a 4- or 5-digit number indicating the next lowest degree of longitude and latitude. For example, RMARC club station WA2SNA, located in Oakland NJ at 74° 15′ west and 41° 03′ north, would use a section designator of 7441.

Each QSO has a point value based on the distance between stations as determined by the larger of the differences between the section designators' latitude or longitude plus 1, with a maximum of 10 QSO points. For example, WA2SNA in 7441 works W3XX in 7838. The difference between 74 and 78 is 2. The difference between 41 and 38 is 3. The larger difference is three; adding one to it results in 4 QSO points.

The section multiplier is the total number of different sections worked per band. The following band multipliers are used to determine the final score for each band: 50 MHz = × 2, 144 MHz = × 1, 220 MHz = × 8, 432 MHz = × 4, and 1296 MHz = × 16. The score per band is equal to the total of QSO point values per band times the section multiplier times the band multiplier. The total score is the sum of individual band scores.

ENTRIES:

Prepare a separate log sheet for each band. Heading information must include your station callsign, section designator, and class of entry. Each QSO entry must include the date and time in UTC, callsign, section designator, and QSO point value. Each band summary must include the total of QSO point values and the total of different sections worked.

One entry sheet should be prepared for each band. They should include the band, QSO point total, number of sections, band multiplier, and band score. Also include the total of all band scores, your station callsign, your section designator, ARRL section and division, and mailing address. It must also be signed by the licensee or trustee of the call used.

Until May 1, you may send an SASE to the Ramapo Mountain ARC, PO Box 364, Oakland NJ 07436, to receive logs and entry forms.

HAM HELP

I am looking for original copies of the TME 11-227 and TME 11-227A directories of WWII German and Japanese radio equipment. I also need intelligence equipment from pre- and post-WWII such as the SSTR-1 and the SSTR-5.

Tony Grogan WA4MRR/F0NZ
5 Rollingwood Dr.
Taylors NC 29687

I want to get in touch with people who are experienced in dealing with power companies and who know what can be considered normal or abnormal power line noise.

Gary Mitchell KH8AC
PO Box 164
Cornwall Bridge CT 06754

Could someone please help me find a manual for the Telequipment model D-66 oscilloscope? It was made in England. I will gladly pay for the manual or for a good copy of it.

W. G. Driscoll KC4KE
6060 James Rd.
Austell GA 30001

I would like to locate the manual and schematics for the Hammarlund HFM-40. I will pay for postage and copying costs. I am also interested in hearing from anyone who has put the HFM-40 on 6-meter FM as a repeater.

David Kelly N4HHE
4223-D Myrtlewood Dr.
Huntsville AL 35805

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 8

which is sought in schools, but merely that the right system be used in getting an answer.

We know that some people have no problem at all in learning the code. These people normally see no reason why everyone else shouldn't have to learn the code, too. I'm fortunate in that I am able to get my code speed anywhere I want it in a jiffy. A few hours and I'm zipping along. It took me maybe a half hour to learn the code in the first place and just a few hours to get to 13 per. The nervousness of the exam put me off the first few times I went down, but finally...after not having practiced more than an hour total since failing the test, I went down...more to help another chap than to take the test myself. I decided that well, heil, as long as I was there, why not? Passed—no strain.

Others are able to rack up hundreds of hours trying for the big 13 and develop quite an inferiority complex over the situation. They try code tapes, copying over the air, classes, and so on. Nothing works. I'm talking about reasonably intelligent people. The army found that a certain percentage of their recruits were just flat unable to learn the code, so they would try them out for a few days and get rid of the people who were difficult learners.

Now, if a person makes a serious effort to learn the code, but is prevented by a lack of the right brain circuits, I assume that this is the kind of stupid person we want to keep out of our hobby, right? And I assume that no matter what this person has achieved outside of this code failure, he should be prevented from getting a ham ticket and bothering us. I have in mind some absolutely brilliant electronics engineers I've known who tried and tried to get the code and just couldn't...who needs that kind of trash on the bands?

No, the majority is probably right in pushing hard for us to keep our present system of encouraging everyone to cheat as much as possible on the technical exam, using the Bash materials so they don't have to know one damned thing about electricity...and sorting it out with the fabled code test...unless, of course, they buy those California tapes...in which case, they will have in their hands the actual FCC code test. Oh, well, we can't win 'em all, right? Will these tapes be available in Dayton again this year? Bet they will.

More than changes in the exams or in the code tests, perhaps it is time for us to consider putting more of the responsibility for the growth of amateur radio onto our clubs. Right now, most of our clubs attract newcomers, who attend a few meetings and then get bored, dropping out. For the most part, I've been finding our ham clubs in the hands of a few old-timers who like to get together and meet each other. Not much more than that happens. I see youngsters very rarely at club meetings and when I do, I often hear grumbling by the grizzled old men who sit toward the back of the room in a separate group.

Perhaps we are happy with a dying hobby and perhaps these old-timers are absolutely right...we shouldn't make any changes. Why should we go out and try to get 12-year-old kids into hamming? They're a bore on the air and create trouble at club meetings. Besides, all this stuff about needing kids so they can become career engineers and technicians is a waste of time...we can buy all we want from Japan and other Asian countries. Heck, even if we did develop technicians, our companies couldn't afford to compete with Japan and Taiwan...wages are too low over there. And besides, their governments are backing their electronics industries while ours is doing its best to screw ours.

Yes, perhaps the old-timers are right and the situation is completely hopeless and there is no use in even trying to do anything about it.

But, Poliyanna me...always the hopeless idealist...I keep thinking that if we could only get our ham clubs to get into the excitement of recruiting youngsters in the 12-15-year age bracket...infect them with the virulent virus of hamming...run classes as part of our club activities... and then have it so our clubs could give the license exams instead of wasting FCC money on this, we just might get some growth started.

We have such an incredible way to go to even catch up with Japan, much less get ahead of them again in electronics, that even if we were to get ham radio growing at 33% per year, it would take over ten years just to catch up...and a few more years to get ahead again. It may take that long before the government (congress) recognizes that business needs help, instead of regulation and taxing, if it is going to compete on a world basis. I really hate to see the US losing one electronics market after another to Asia...because we have so few technicians, so much difficulty getting growth capital, minimum wages driving up costs, so little emphasis on automation and robotics...and so on.

When I looked into building a new plant for our Instant Software division, I found where the bottom line was. Let's say I wanted to set up a plant with $100,000 worth of equipment to produce a product which I would sell largely worldwide. Now, in the US, before I could invest the $100,000, I would have to earn $200,000 and send half of that to the government in taxes. In Ireland, I found that I would have to invest only $50,000 and the government there would match that, giving me the needed $100,000. Further, the government would train workers for me at their expense...and wages would be far below ours to boot. Is it any wonder that Apple, Memorex, and many other firms expanded into Ireland instead of adding facilities here? You get four times the bang for the buck there, so businessmen put down their waving flags and were practical.

Getting back to hamming...one of the reasons I have been pushing so hard for all these years to get the legislation through to allow clubs to give the tests is my faith in the clubs as the best approach we have to getting growth of the hobby. Now that the law has been changed to permit this, I'm anxious for us to get started. I believe that if clubs do the teaching of our newcomers *and* the testing, we won't need any FCC tests or code. The clubs will know who is serious and who isn't. I'm hoping that this sort of entry Into the hobby, where newcomers are taught not only theory, rules, and such, but operating procedures and ham lore as well, will result in much better hams.

In the meantime, I'll be pushing where I can...publishing articles on construction projects...and so on, all trying to keep things moving in the direction that seems most productive for hamming... and our country...in the long run. I'd sure like to have your help and support, but I'm used to being fought and jammed, so I'll do my best with or without help.

BASHED YET?

Yep, my good friend Dick Bash is at it again. You really have to give him a lot of credit. A lesser person would have become discouraged when the FCC changed the test on his blitz-taught students and flunked almost all of them. Well, Dick had their money, so it was no skin off his...er...nose, right?

So Bash is going out again, giving his one-day intensive memorization of the FCC answer courses, all for the low, low price of $150 for the Tech/General or Advanced, or $225 (wow, a bargain!) for both. Dick has a nice guarantee for you, too... if you pass, he keeps the money. If you flunk, he keeps the money. What could be fairer than *that*? Oh, if he runs the class again, you can take it again for free if you can find it. If you don't register ahead of time, it's $25 more at the door for each course.

Will the FCC be waiting for their nemesis again with a new exam and flunk his trusting flock? Heh, heh, only the Shadow knows.

If the FCC doesn't change the questions, Bash will definitely get you ready to pass the exam. And you don't have to worry one little bit about having to learn a thing about electricity or radio. No knowledge or understanding whatever is necessary to pass this test once you have been grilled in the answers for a full day. But better not wait a day or you may start forgetting some of the test answers.

Bash will be going around to Seattle, Los Angeles, San Jose, Chicago, Boston, and Dallas. Let me see...with about thirty students per class, twelve classes in about a one-month period, ole Dick is going to really rake it in. Who says you can't make big money out of amateur radio? Not counting all of his sales of books and code courses ($10), it looks as if Dick could pull in $45,000 in that one big swing. Hey, good work there, Dick!

I don't know if Dick picked up the FCC's actual code exam from the booth near his at Dayton, but if he did, you are really in luck. Why, you would then be able to pass the whole FCC exam without knowing either the code or the theory, rules...or anything! By golly, if we can't get some growth in the hobby this way, what *will* do it?

ANOTHER OGRE

Not all of the falling behind of electronics manufacture in our country can be laid at the feet of the ARRL and their incentive licensing disaster of 1963. The resulting loss of engineers and technicians to the country has been devastating, but there have been other factors involved which have worked to cut American production and put Americans out of work.

One of the more insidious robberies of jobs has been caused by the borrowing of cash by the government to pay the increasingly large government debt. They've done this via short-term, high-interest notes which investors have been buying. According to the most recent figures, the government is now responsible for 29.7% of *all* borrowing. This has doubled in the last decade and has a lot to do with the unemployment situation.

Remember that the more profits companies can make, the more they will expand their operations, creating jobs. And as people make higher salaries they will spend more, again creating jobs. But when the government comes in with super high interest on their borrowing, this takes billions away from the private sector...billions which would otherwise be invested in making more jobs.

The deficit of 1982 is mind-boggling, of course, but one sadder result of this is that the 200 billion will have to be borrowed from investors, further robbing our industries of investment capital and thus preventing them from investing in growth and the badly needed creation of jobs.

This bleeding of investment capital by the government reflects back on us in another insidious way, too. By keeping our industries from getting reasonably-priced money for modernizing plants, they are forced to be ever less competitive with foreign manufacturers. Today, the US has the highest percentage of obsolete plants, the lowest percentage of capital investment, and the lowest growth of productivity of any major country.

This is a difficult situation for those who want to expand welfare and unemployment benefits. In order to get the money to pay people who are not working, we have to borrow it from those who are. And when we use money in that way, the government has to compete against our industries to borrow the money, taking it from them with higher interest rates. Yes, these people spend the money, but make nothing for us to buy in return for it, so the capital thus used up does not end up making more. This unwinds the economy and makes us less productive.

There is no simple answer to everything, but we do at least see a lot of the problems which are sinking our country. The lack of capital for building new and modernizing old businesses is damaging. The lack of trained technicians and engineers puts us at a further disadvantage. If we did have the cash to expand electronics production, we would probably send it to Asia, where we would get more return for the investment because they have more and better technicians there.

If we are able to start getting our kids interested in amateur radio, we could, in a decade, begin to turn the engineer and technician problem around. The cash situation is not going to improve until we make it clear to politicians that we are serious about eliminating deficits. I note that there are a lot of senators and representatives who do not yet have this message...which means that we are not making that clear.

TOO MUCH SCIENCE?

On my birth cerificate, it lists the occupation of my father as "aviator" and my mother as "artist." If you think about that, you'll get some insight into my trains and lapses of thought. There is the mixture of the mechanical and the artistic which resulted in a technical publisher.

This same background has led me to be interested in both the scientific explanations for the world and the occult ques-

tions which science has been unable to answer. Science has done a good job of answering many questions about how the universe works. But it has also failed to successfully tackle a great many observable phenomena. We have come to terms with many of these via religions, which call for belief without scientific proof. Other questions which are not answered either by science or religion tend to be pushed aside with annoyance.

But it is dishonest of a scientist to deny the existence of data just because he is unable to explain it or set up an experiment which repeats it. Science, if it is going to be true to itself, is going to have to admit that there are a lot of things which do not fit into the framework of the universe that they have built up. Scientists are going to have to start seriously trying to understand pesky things such as UFOs, ESP, reincarnation, PK, the spirit body, how memory works and where it is, medium communication with the dead, ghosts, and so on.

The easy path pursued by most scientists has been to unmask a few charlatans and then ignore everything else. Proving that a few of the UFO photos are fake doesn't solve the UFO situation at all.

The more we interest our kids in technical hobbies, the more scientists we'll end up with. You don't develop first-rate scientists by starting people in their 20s any more than you get good ballet dancers from late starters. No, it takes the twist of mind provided by amateur radio or computers (and I think we can all agree that these hobbies definitely do twist the mind) to get a good scientist going.

Dr. Hynek, the outstanding scientist investigating UFO phenomena, got his start as a ham. His credo seems to be much like mine...pointing to a wealth of data and a paucity of provable explanations...and asking if anyone can come up with a theory to explain all of this.

For all of our wonderful progress in science and the high technology gadgets we have derived from it, we still have an enormous number of rather key things which we don't understand and thus have to accept on belief. Once we start getting a handle on some of these mysteries, we will have powerful tools for further progress. Will an understanding of the essence of man lead to time and space travel in some mode barely dreamed of today?

Or will we find out that there really is some benefit to praying to the coffee table to have a nice day?

The questions are there in large numbers. We have to find out more about talking with plants, Kirlian photography, mind photographs, bent spoons, and so on. Can an understanding of human memory lead us to design computer memories in a different way, perhaps ridding ourselves of all size limitations?

Until we understand all of the mysteries of our world, we have plenty of room for science to work...and we need a good supply of new scientists. Hopefully, there will be a few more with the combination of the artistic and the mechanical...the scientific and the metaphysical...so that we will have some scientists able to tackle these things. Just ignoring them and refusing even to think about them is not a scientific answer.

In the past, I have written about such odd phenomena as UFOs, both about my own experiences in this field and those of other readers. I got quite a bit of mail from hams who had had personal UFO experiences. The easiest way to handle things like this is to ignore them. There was a "Nova" program recently which went to rather great lengths to debunk UFOs. And since then, I've read quite a bit about the films they took for the show which were not shown...or even mentioned...films which give strong evidence that something odd really is going on. For some reason, they wanted to do another whitewash on the subject.

The same situation surrounds many of the anomalies which perplex the more thoughtful and open-minded scientists today. One can still find scientists with good reputations in some field who refuse to accept that there is any such thing as mental communication. Yet most of us have experienced this at one time or another, so we know it exists...and wonder at the objectivity of someone who won't even check the evidence. I will never forget some emotional distress I was under one day many years ago. I was distraught...and at that very moment the phone rang. It was my mother asking what was wrong, calling from 135 miles away. She'd never done that before...and never has since. There was no way on Earth that was a coincidence. She knew nothing of any of the situation or its development.

Ask me sometime about the UFO which a bunch of us here at the magazine saw just down the road one evening...and which suddenly sped away over the horizon in seconds when it started moving. We could see it for at least fifteen miles, a distance it covered in about four seconds—after hovering for several minutes.

There are a lot of things to investigate...if we can develop enough scientists...and they are able to break away from orthodox thinking enough to handle these elusive problems. But until we start getting more kids started in high-tech hobbies, our chances of making progress will be slight. Has *your* ham club done anything to spread the ham radio bug in your local schools?

DOWN WITH DXCC

My recent editorial pointing out the harm which DXCC and the Honor Roll has done to our hobby brought in an interesting letter from a well-known DXer. His response was to attack me, not the ideas which I had discussed.

The problem with DXCC is that it puts a premium on making contacts with operators in rare countries. This, in turn, if you stop even for a moment to think about it (which may be too much to ask DXers), means that operators in rare countries are not permitted to get on the air and ragchew. Now, let's think about that for a minute. What is the most popular aspect of amateur radio? No, rag-chewing is by a wide margin the most popular amateur radio activity. We see the bulk of our low bands used for this, as well as virtually all of our VHF operation.

What chance does Paul 9M8PW in Sarawak have to rag-chew? He is no sooner on the air than the pileups start, with ops getting ever more insistent that he stop talking and give them a report and a QSL. They don't want to know about the Sarawak River and the twenty-foot-long croc which has been grabbing children up river. They don't want to know about Paul and what he teaches or that the monsoon rains have flooded half of Kuching that morning. They don't really care that his name is Paul or how long he has lived there or what he is doing...they want a QSL card so they can get a certificate. Many callers have no idea of where 9M8 actually is.

It turns out that Kuching is a fascinating place to live. Just a generation away from head-hunting, the people there are friendly and hard working. Once you get away from the capital city, you find that many of the small towns are built on stilts. Not just the houses, but entire villages are on stilts. They call them long houses—often they contain hundreds of families living together. Each family has a separate set of rooms, but they are together, sort of like a bamboo-made hotel or motel. The ladders down to the ground are made out of single trees, notched to provide the steps. The people zip up and down these narrow stairs just as we do our three-foot-wide staircases.

Having towns on stilts keeps them above the water that runs off on the ground after the monsoon rains, which hit just about every day during half of the year. The temperature is comfortable, even though this is only about a hundred miles from the equator, running about 70° at night and maybe 88° during the hot afternoons. The humidity? Ugh! The rains last a few minutes to maybe an hour at a time, so you can usually outwait them.

Living is easy in a place like this, with hunger unknown. Wild bananas and pineapples are all around, coconuts, and so on. All sorts of fruit and vegetables grow in profusion. You just plant 'em and jump back. And living up off the ground not only keeps you away from the floods after each rainfall, but also keeps you away from most of the small animals and bugs. It's cooler, too. Even in town, many of the houses are built up in the air, with an open parking space for cars on the ground level.

But each remote country of the world has a different story to tell, if you'll listen. However, until we take off the pressure of the awards for getting QSL cards from rare countries, how are we going to share in these things? And how are we going to make hamming fun for ops in these spots?

I enjoy getting on for a few days from some weird place and making thousands of contacts. But remember that I do this for fun. I know that if I were to live in one of these places, I would get pretty tired of the unending pressure for the shortest contact possible, writing down calls month after month so chaps can get QSL cards. The paperwork involved is a drudge.

It's no wonder that every now and then we develop a DXpeditioner who uses this pressure to make money. People on the Honor Roll will eagerly pay $50 each for a contact with a new spot. Indeed, that was the going price ten years or so ago. I'll bet that a mercenary today could ask for and get $250 each for a new country. The charge for those not on the Honor Roll would be down to around $25. If I ever retire from publishing, I just might grab a couple of portable rigs and set out to prove that I can make $100,000 a year via DXing.

Now, for those readers who have not followed my personal enthusiasms, I'd like to assure you that you will have to look hard to find a more energetic contester. And I think I can keep up with anyone in the world when it comes to making fast contacts from rare spots. I've got that down to a science now, if you'll break quickly with the last letter of your call, please. Hold off for a few seconds and give it to me just once phonetically and I'll get you. If you give it twice, you'll go to the end of the list. I don't just work the loud stations that way—I work right down to the weak mobile stations and other rare DX callers.

Can anything be done about DXCC and the Honor Roll? Of course not, but that isn't going to stop me from beefing about what it has done to amateur radio. Who knows, I may come up with something even more pernicious.

ASIAN TOUR

Speaking of Asia, I'm sponsoring a tour of Asia for this coming May, if you're interested in a first-class trip. This will be a short one, running about two weeks, and will visit Tokyo, Taipei, and Hong Kong. This is aimed more at the computer aficionados, so it will coincide with the microcomputer show in Tokyo, plus smaller get-togethers in the other countries (which are not as deeply into micros as Japan).

The tour will use the best of hotels...strictly first-class...and includes breakfasts and even some of those spectacular dinners. Having just returned from one, I can tell you that they are truly first-rate.

In Tokyo, we'll try for a meeting with the TIARA, the Tokyo International Amateur Radio Association. You'll not want to miss Akihabara, the electronics section of Tokyo, with hundreds of stores selling electronic equipment, ham gear, parts, and so on. You'll find most of the ham rigs running about 50% to 75% of the American price...unless you wait for Hong Kong, where they are generally even lower.

You'll get a kick out of Tokyo. The subways are easy to use. There are McDonald's all over the place in case you get a Big Mac attack...plus all the old home features such as Shakey's, Kentucky Fried, and even Wendy's. For the more adventurous, there are all kinds of Japanese meals, from raw fish right on through. This last trip, we had a complete raw-fish meal, with two courses of raw whale included...courtesy of the chaps at TDK.

If we get some hams on the trip...and you're interested...I'm sure we'll get a good reception from Kenwood as well as TDK...and perhaps Yaesu. We'll be too far away for Icom, unfortunately... wonderful people.

In Taipei, you'll enjoy the city...the people...and some of the incredible things you can see there. We can certainly get together to meet Tim Chen and see the radio club...and BV1A. I don't know if we can swing it to let you sit down at the mike of the station or not...but it's worth a try.

The next stop is Hong Kong, where you won't believe the prices on electronic equipment. There are dozens upon dozens of small shops, all trying to outdo each other. The city is big, with hundreds upon hundreds of high-rise apartments and business buildings. Transportation? Anything and everything...from modern subway to trishaws. I like Phil VS6CT's approach to crossing the ever-jammed streets. He just steps into the traffic without looking at the cars and they always stop for him. It takes some guts to get used to his system, but I can assure you that it works. He's lived there for years and is still alive as testimony.

If you bring along an HT, we *can* get ham tickets in Hong Kong. No problem... get 'em in minutes. They have a repeater, of course.

The ferry across the bay between Hong Kong and Kowloon costs 8¢ for first class, as I recall. Wonderful sight—and you'll get great pictures.

The tour starts from Los Angeles on May 20th and will be returning two weeks later, June 3rd. This is immediately after NCC in Anaheim, which runs May 16th-19th. I'll be there for NCC and then go on the tour, so if you go, you might not only have someone interesting to talk to, but you will also have someone who really knows the ropes.

If you have the wanderlust as I have, you may want to delay your trip back for a few days and add some other countries to your trip. This can be done remarkably inexpensively. Travel in that part of the world can be surprisingly low-cost. This last trip, I added a bunch of extra stops to

the tour, going to Singapore, Bangkok, *Kuching (Sarawak), Brunei,* Sabah, *and* Manila. I traveled a day and then visited two days, taking three days more for each country visited. The hams in each country were first-rate. The hotels were fine (except for Brunei...and now I know of a good one there) and the food superb. I gained five pounds on the trip...despite my jogging just about every morning. You'd laugh to see me running three and four miles in the early morning through the streets of Taipei, stopping now and then to snap a picture.

Other than imitation diamond-encrusted $15,000 Tifffany watches for $30, what bargains are there in Taipei? Plenty. You'll be shopping up a storm in the department stores there. You'll also get pretty sharp with chopsticks.

I don't have the exact price of the tour yet, but I'm sure it will run no more than around $2,500 for the air fare, hotels, many meals, all ground transportation, tips, airport taxes, and so on. Also, when you are in a group like this the usual baggage limits are waived, so you can pick up all the souvenirs you want. Drop me a line if you're interested and I'll send your letters on to Commerce Tours in San Francisco, the firm we work with on trips like this.

TAIWAN IN TROUBLE

Taiwan has been growing almost incredibly in exports over the last few years, but they are getting into deep trouble these days...mostly as a result of their success. Most of the products of Taiwan have been labor-intensive, depending for their success on low wages. But now, as their wages have escalated...inevitable with only a little over 1% unemployment...they are becoming uncompetitive with similar goods from other low-wage countries such as the Philippines, where the minimum wage is around $2 a day and many people still have to live in the streets.

The obvious route is to change from labor-intensive goods to higher-priced things such as electronics...but here they are up against an educational problem of enormous proportions. Japan made this change from inexpensive exported goods to high-priced, high-tech manufacturing years ago and has built up the infrastructure of education needed to support such an industry.

As any DXer is well aware, there is exactly one ham in Taiwan. I had the pleasure of having breakfast with Tim Chen BV1A during my recent visit to Taipei and discussing this with him. Tim had some hope because there is a move underway to bring more people into amateur radio in Taiwan which could eventually result in dozens of stations on the air. In the past, the government has discouraged new amateurs or even shortwave listening, with the result that there has been no real incentive for kids to get interested in radio. This, in turn, has made it so that there have been very few electronics engineers or technicians in Taiwan.

I've been getting to the Taiwan Consumer Electronic Shows for several years now, seeing their products and talking with the manufacturers. I've also endeared myself to businessmen of Taiwan by pointing out what they already know... that their electronic equipment is all imitative, with no creativity in evidence. Thus their equipment has had to sell almost entirely on price, with new ideas and quality taking a back seat.

Lacking the scientists to develop new products, or the engineers to put in automation and robots, Taiwan has had to depend mostly on copying the equipment from other countries and on their low wages. Now, with their wages rising faster than those of the rest of the world, they are in trouble, and they haven't the supply of engineers and technicians to turn to for help.

Business has been brisk in recent months in rip-offs of the Apple computer. Again, lacking anything significant in technicians, Taiwan manufacturers have had to turn to copying the most successful of the microcomputers, the Apple. There are over a hundred small firms... and some fair-sized ones, too...making Apple imitations. I saw them everywhere at the electronics show in Taiwan and even had a chance to talk with some of the manufacturers personally.

If Taiwan is able to get kids interested in high-tech hobbies such as amateur radio and computers, the country could, in a few years, be able to get away from trying to make a living from the ideas of others and come up with creative ideas of their own, as has Japan. Within the memory of those of us who were around in WWII is the image of Japanese products as being junk. For many years, most Japanese products were cheap imitations of better products, with shoddy workmanship.

Today, as you know, not only has Japan set the world standard for productivity, but also for quality. They've left most other countries far behind in these regards. And in the last few years, we've also seen the emergence of Japanese creativity.

Though I put a good deal of emphasis on the importance of getting kids into high-tech hobbies as a way for a country to develop technicians and engineers, I am among the first to agree that this is by no means the only problem we have in trying to compete with the Japanese. But without being able to match them...or even come close...in engineering talent, no amount of government help of industries, more favorable tax climates for electronics firms, etc., is going to help us to regain world superiority in technology.

There have been a number of good programs on television lately showing the difference in education between the US and Japan (and even Russia). Our schooling system has disintegrated a good deal since I went to school, with math, sciences, and so forth being almost done away with in many areas. No wonder kids are having a problem even with the Novice ticket, which anyone with a high-school science education should be able to pass. The fact is that few kids *are* getting a high-school science education. Phooey.

Oh, there are a lot of things we need to overhaul...and I will make few friends by bringing these things up. One only has to read the reports in *Reader's Digest* on the activities of unions to terrorize uncooperative manufacturers to realize that America has no monopoly on human rights. While we are indignant over the Israelis making life extremely miserable for the Palestinians, the torture in Argentina, the executions in Guatemala, and so on... things which are going on all over the world...we have not too different things going on right here which we want to cover up.

The worker who works harder than his fellow workers is harassed until he slows down and stops making everyone else look bad. I saw that one myself back when I worked for a company which made transmitters for the Army. The union there was furious that the test people didn't just pass along anything put together by the production people...and never mind that the transmitter would be needed by the Army in working shape. When I got busy and turned out about double what my fellow workers could manage a day, they started sabotaging the units I'd aligned to prove that I was turning out poor work. No, I've been there, so when I read about this happening all over the country, I tend to believe it.

We geared up and won WWII, getting the cooperation of millions of people. I think we can surmount the current depression if we make a decision to do it and stop our own people from fighting each other. Unions can do worlds of good to help people and production...they can also drive you crazy with featherbedding, slowdowns, restrictive work rules, intra-union fighting, and so on. Unions which insist on using every weapon at their command to maintain their members at higher than the normal wage for their work are robbing the rest of us. This comes to roost when they come up against foreign competition, such as with cars. American cars would drive the Japanese cars right out of the country if the car unions would settle for average wages for their workers and put on the pressures for productivity and quality.

When I have to rent an American-made car on a trip, I am invariably amazed at the poor performance and quality of the product I am driving as compared with my Japanese cars. That door doesn't fit right because someone on the production line just didn't care...and the inspector was under union pressure not to make the worker look bad...or was out on coffee break when my car went by.

Well, the world is changing. More and more "workers" are going to be replaced by robots who do not forget a few screws and bolts when assembling a car. Robots will make the windows fit exactly right. Robots will not call in sick when a DXpedition is brewing on 20m or when hung over from too much brew the previous night. Workers are going to have to think in terms of education...perhaps with some science in the mix so they will be able to cope with the type of work we have today...and will have in the next twenty years.

The world of 1999 looks to me as if it is going to be a high-tech world, with telecommunications on the order of 10,000 times more than we have today...with people able to communicate with others anywhere in the world in seconds from small hand-held computer-like communicators. We'll have teleconferencing and so on. But these developments are going to call for an incredible number of technicians, engineers, and scientists. Our present school system is totally inadequate to cope with this need.

Taiwan has the same problem, only it is hitting them hard right now. They need thousands of technicians and engineers and they need them today. In all of Taiwan, I found one firm with an innovative computer product. That was the Micro Professor, which looks like a comer. It will run Apple programs, but does not appear to be an Apple rip-off, even in its electronics.

One is struck by the impact of the lack of copyright enforcement in Taiwan. Not only are there many bookstores full of cheap copies of almost all of our best-selling computer books, but one can also go into stores all over Taipei and buy a $15,000 watch for about $30. Sure, it's a copy, but a good one. I picked up some local copies of Apple manuals...and saw any number of copies of well-known programs, usually selling for about $10. Not bad for VisiCalc. Within days of a new program coming out in the US, it is available all over Taipei for a few dollars.

Taiwan will be able to shift to higher-tech products and thus make more income per sale...and be able to pay higher wages...if they have the technical people to cope with the changes in world technology. To me, this means getting their kids into high tech and providing the schools they need to take this interest and develop it.

HAM HELP

I have a Midland model 13-866 CB radio which I converted to 10 meters, following the modifications outlined in the April, 1981, issue of *73.* However, it does not receive on 10 meters, the transmit signal is garbled, and it will not change frequencies. I need information on how to make it work.

Joe Oden WD0HYM
4129 South Wichita
Wichita KS 67217

I need the following items: horn speakers, spark gear, high impedance headphones with cords, 201A (or equivalent) tubes, old terminals, bus-bar wire, vernier dials made prior to 1930, 2- to 4-inch bakelite 0-100 dials, and telegraph keys.

Alan Shawsmith VK4SS
35 Whynot St.
West End, Brisbane
Q 4101, Australia

I am looking for construction plans or a schematic for a one-tube QRP rig.

MacArthur Moore
5230 Heston
Philadelphia PA 19131

Could someone help me find the schematic for an Eico model 150 signal tracer?

A. B. Wells WA5COM
PO Box 50
Tunica LA 70782

I am looking for CB magazines printed prior to 1967.

John W. Heacock K3YCP
8100 Bass Lake Rd.
Apartment 110
New Hope MN 55428

I am trying to find the manual and replacement capacitors for a Hallicrafters Sky Ranger S-39 receiver. I also need an operational or as-is DX-40 transmitter and a manual. I am willing to cover copying and postage costs

Dave Drinnan VE3MPX
21 Beaverbrook Lane
Kanata, Ontario

REVIEW

THE AEA CODE TRAINER

Everybody has his own way of learning the code, and most people think that the way that they learned it was the best. It was with this possible bias in mind that I approached the AEA BT-1 code trainer, a Morse-code training device that uses no tapes but an IC to produce the tones.

AEA, which specializes in keyers and code readers, should know the code better than many manufacturers, and this knowledge has led to a novel approach for learning the code. The BT-1 is designed for use by people who are completely unfamiliar with Morse code. With the trainer, you move step by step through each character, singly and then in groups.

So far, this is pretty standard fare. However, the machine does not teach the code from simplest to more complex, for example from E to Y. The first character learned is F, and from there the student moves on to K, B, Q, and the last letter learned is I.

In addition, the code trainer does not begin sending each character at a slow speed. Every character is at its 20-wpm length, regardless of the spacing between characters. As they explained in the manual, this is to overcome the proverbial plateau many people encounter at about 10 wpm. By learning the sound at a higher speed at the start, your ear will have to adapt less as you increase the code speed.

AEA also suggests a strict adherence to the sequence of characters which they suggest. After learning to recognize each character, both by itself and in groups of increasing length, the student moves to the next character. As he or she moves down the list of new characters, the characters previously learned are thrown into the groups at random. However, the character being learned is weighted at 50 percent—that is, one-half of the characters will be the new character.

Once all of them have been learned (the list includes numbers and common CW ciphers), the student can increase the speed by decreasing the spacing between characters and changing the character length as well. Each training selection may also be called up without weighting the new character, making the characters of each group completely random.

The BT-1 has several accessories which enhance its use, such as a full-sized headphone jack instead of a ¼-inch earphone jack, and a second jack in which a key may be inserted for use as a code practice oscillator. The pitch of the tone is also selectable in discrete steps, adapting the trainer to a variety of ears. Its small size and the included nicad battery pack and charger make it extremely portable, so you can get your daily half-hour of practice in many situations.

A 12-button keypad controls the operations of the BT-1. However, one of the difficulties in using the trainer is learning the commands which control it. All of the commands, except for the stop command (#), are at least 2 keystrokes, and in most cases 4. I found that to use it I had to have the manual close by at all times for quite a while until I learned the proper commands.

Because of the relatively complex controls, the speed at which you are copying is also difficult to determine. One command sets the character speed from 18 to 99 words per minute, and another command sets the delay between groups of characters. The delay range is from 0.1 to 9.9 seconds, with a default value of three seconds. The character speed default, as mentioned above, is 20 words per minute.

AEA's BT-1 code trainer.

For this reason, as well as the somewhat limiting factor of listening to code in purely random groups, I found that the code trainer worked most effectively in conjunction with tapes. For characters with which I have difficulty, such as X and some of the CW ciphers, I drilled myself on the BT-1 to increase my proficiency. But to increase my overall speed, I found that I used tapes. With the known speed for the tapes, it was easier to keep track of my progress, and it alleviated the boredom of listening to and writing random groups.

However, I would recommend the code trainer to Novice classes and individual students. AEA's method, while not the standard procedure, seems to work. The portability of the unit would hopefully lead to more frequent use. And, as we all know, there is no substitute for diligent practice when trying to learn the code.

THE AZDEN PCS-4000

The progress of large-scale integration (LSI) has left hams somewhat in its wake, because this technology is highly dependent upon the economy of scale—the more you make, the cheaper they get. The amateur market is often too small to bring the advantages of LSI to bear in new products. However, Azden has brought amateurs back to the state of the art with the intoduction of its new PCS-4000 2-meter transceiver.

Azden's use of LSI has enabled it to produce a microcomputer-controlled radio that is little larger than the average in-dash AM radio. The PCS-4000 measures 2 inches high by 5½ inches wide by 6¾ inches deep, and much of this miniaturization has been accomplished by replacing mechanical control mechanisms with logical functions performed by the microcomputer.

All of the transceiver's tuning is conducted through the 16-button keyboard, which doubles as a touchtone™ pad. The Azden has an extended range of 142 to 149.995 MHz and frequencies may be selected in 5- or 10-kHz steps or from the two banks of 8 memory locations. The relationship between the memory banks is controlled by a 4-position memory mode switch. This switch allows the operator to choose a frequency from either bank, both banks, or select a receive frequency in one bank and a transmit frequency in the other. By using this switch, non-standard repeater offsets may be programmed into the machine.

Standard offsets and simplex operation are also selected via the keyboard, and the offset may be stored in memory with the chosen frequency. Nine LEDs indicate the memory address and bank currently in use.

Other indicators on the front panel include the green LED frequency display, which indicates the transmit frequency as well as the receive frequency, a digital S-meter, and a channel-busy indicator. Other LEDs show whether the PLL circuit is locked, which offset has been chosen, and whether the frequency is from the memory bank or has been directly keyed in.

Besides the volume, squelch, and memory mode controls, the PCS-4000 sports only 4 mechanical controls. Three switches choose the frequency step, select whether the scanning feature will settle on busy or vacant frequencies, and turn on the optional 1750-Hz tone.

The scanning features may be used in conjunction with the memories, or an entire portion of the band may be scanned to locate either busy or empty channels. These options are also keyboard-selectable. The scanner will also automatically resume after monitoring a busy channel for about 10 seconds, which gives you enough time to decide whether you want to stay on that frequency or not.

The Azden puts out a husky 25 Watts in the high power mode and 5 Watts in low power. Current consumption runs from 0.6 A in receive to 6.0 A while transmitting, and spurious frequency rejection is better than −60 dB.

The receiver has a sensitivity of 0.2 uV and a selectivity of 6 dB down @ ±6 kHz and 60 dB down @ ±15 kHz. The audio output is 2 W into a 2-inch speaker. The receiver is a double heterodyne operating with a first i-f of 16.9 MHz and a second at 455 kHz.

The transceiver is controlled with an MB 8855222M single-chip microcomputer. Circuitry has been sectioned into four boards—the control board, the PLL and transmit circuitry, the receive unit, and a PA board. All of the functions of the PCS-4000 have been packed into 15 ICs, 9 FETs, and 34 transistors.

The flexibility of the microprocessor control system has given the PCS-4000 a variety of special functions which I have found valuable. Besides being able to select a frequency or memory address from the keyboard, a single button will reverse transmit and receive frequencies. I have found this feature useful for quickly finding out whether a station is strong enough to work simplex.

Another very valuable feature not found on many other radios with programmable memories is the nicad backup which Azden built into the transceiver. Although the manual recommends supplying power to the radio directly from the battery, the nicad will preserve the radio's memory when it is removed from the permanent power source. I regularly take my radio inside for safekeeping, so without this feature I would have to reprogram 16 channels every morning. The nicad is automatically recharged whenever the radio is on, and it only supplies enough power to retain the memory; you cannot operate the transceiver from the battery.

The battery comes with the initial charge already completed, unless the unit sat on a dealer's shelf for several months. Azden has included as an accessory the necessary jumper cable and instructions for charging the battery should it be necessary.

There is also one priority channel in each memory bank, in the first memory address. The priority channel in either bank can be instantly accessed, regardless of what bank you are presently operating from. Two buttons on the keyboard are reserved for this function, and the priority channel in the first memory bank may also be called up with the remote control located on the microphone.

The microphone incorporates two other controls as well. The up/down buttons will change the frequency by 5- or 10-kHz steps or will proceed sequentially through the memory if you are operating in the memory mode.

The scanning circuitry has proved to be especially versatile, and with it I have found and immediately been able to access repeaters that I previously did not even know existed. In addition to searching for your choice of busy or vacant channels and scanning the memory or a selected band slice, the scan may be conducted with a repeater offset. For example, if you are scanning the range above 147 MHz, you can instruct the transceiver to automatically add 600 kHz to your transmit frequency.

The 25-W output gives the PCS-4000 a good signal range, and all comments on the transceiver's audio give it a good report card. It picks up little road noise, and the audio lacks the heavy bass component found on some other transceivers.

Although I have had some problems with the transceiver, they have been relatively

minor and can be expected as an operator adapts to a new radio. The microphone button which calls the priority channel is located on the upper tip of the transmit button, and therefore is easily activated when you are pawing for the microphone while keeping one eye on the road. Until I became used to handling the microphone differently, I sometimes would begin a QSO on 146.150 and suddenly find I was talking to the breeze on .52 simplex.

There is also an interesting feature on this radio which could be made more useful. The PCS-4000 will emit a beep whenever a keyboard command is received, enabling the operator to do some extensive radio fiddling while keeping his or her eyes on the road. Unfortunately, the beep is not always loud enough to hear over the road noise.

However, these are minor problems and not integral to the otherwise excellent capabilities exhibited by the PCS-4000. By using the options available on this radio, I have found a versatility in mobile operation previously just imagined and proved to my satisfaction that bells and whistles are not always superfluous, but can become a useful adjunct to my operating. And by bringing state of the art back to hams, Azden has provided an incentive for other manufacturers to try to catch up.

TEN-TEC MODEL 560 CORSAIR TRANSCEIVER

It was with a great deal of anticipation that I sliced the packing tape on a huge shipping carton whose return address said Sevierville, Tennessee—Ten-Tec's home in the foothills of the Great Smoky Mountains.

For some time, those of us involved with the amateur radio industry had been hearing rumors of a new Ten-Tec transceiver reputed to be even better than, and a replacement for, their respected Omni-C. Very few, if any, of amateur radio's press had yet seen the new rig, and it wasn't until the dealer notices were out and some of the ads in hand that any of us really knew what the rig looked like or what its features were supposed to be. The introduction had been carefully planned to take maximum advantage of the traditional year-end buying season . . . a strategy sharing popularity with Dayton's famous Hamvention as an ideal time for the debut of new amateur radio equipment.

Like its privateering namesake, the Corsair was clearly intended to capture a share of the amateur radio marketplace from other well-known transceiver manufacturers. The ultimate test of that effort will be the reception by John and Joe Ham, but, for now, it was my privilege to have one of these brand-new, solid-state transceivers for evaluation. The *73* staff had requested that a full complement of crystal filters be provided to take care of RTTY and CW needs as well as SSB operation, so it was with considerable excitement that I finished opening the box. Time to see what was inside.

Two other cartons inside the large one appeared: a small and rather heavy one, and a somewhat larger but lighter one. Opening the small one first, I noticed the foam-in-place packing material completely surrounding the contents, conforming to every contour of the equipment to protect it from transit damage. Pulling this aside, I found the deluxe power supply neatly bagged in a heavy transparent plastic envelope. "What a good-looking unit," I thought as I set it on the operating desk. "Ooh, what a pretty radio," said my wife who had been watching the unveiling. "Is that your new rig?"

Next, I opened the larger carton and again found the same secure foam surrounding another plastic-bagged unit. Here was a piece of gear that looked good even before it was unwrapped, and I thought back to all of the earlier Ten-Tec equipment I had seen come from the box: my first PM-1, then the PM-2, the Argonaut, the Century 21, the Models 540 and 544, and the Omni series. All were innovative and unusual, presenting new ideas and approaches in performance and styling for solving age-old problems. It is no wonder then that I keenly anticipated the setup and operation of the new Model 560, Corsair.

The Corsair is slightly wider than it is deep, and one's first impression is of crisp, contemporary styling and no-nonsense, rugged construction. A band of darkened glass along the top of the front panel is set off from the rest of the panel by a trim stripe cleverly painted to look like brushed chrome or aluminum, which nicely sets off the bronze-black finish . . . guaranteed to look attractive on my walnut operating desk.

The six-digit LED frequency display and the meter, next to it on the left, lie behind the glass band, called a "blackout" display because when the rig is off, neither the display nor the meter is visible. When lighted, the display is large and easy to see: five digits in red and the sixth in green, showing 100-Hz steps. The meter is also easy to read and presents four selectable functions.

The speaker/power supply matches the decor of the transceiver, and together they make a handsome pair sitting side-by-side on the desk. Black knobs with bright-metal centers peaceably coexist with aluminum toggle switches for the most frequently used controls, while smaller knobs in a flat black finish serve the set-and-forget functions. A tilt bail under the rig allows the front of the rig to be raised to a comfortable viewing angle. The standard four-in microphone connector and the usual earphone jack immediately above it occupy the lower left corner of the panel.

Dominating the center of the front panel is the tuning dial with its fluted knob and vernier skirt. It is divided into 100 increments, each representing one kHz, to facilitate frequency reset and supplement the LED readout. The accompanying photograph reveals more than a detailed description for the moment, so we will leave that until later. First, let's take a look at the more technical aspects of the rig.

The Corsair transceiver from Ten-Tec.

General Description

The Model 560, Corsair is a medium-powered transceiver employing the latest solid-state technology. As received from the factory, it contains all necessary crystals for operation in the 160-, 80-, 40-, 30-, 20-, 17-, 15-, 12-, and 10-meter bands (full coverage of the latter). Although intended primarily as a fixed station, it may be used mobile or portable because it operates from a 12-14-volt-dc source or from a 115-volt-ac source through an optional external power supply. Broadband circuitry eliminates the need for tune-up, and the normal sideband for the band in use is automatically selected when bandswitching. LED indicators are provided so the operator can tell at a glance which particular functions are in use. Nominal input power is 200 Watts, and full output power at a 100% duty cycle (RTTY and SSTV buffs take note) is available on all modes and bands. Further, the Corsair is capable of operating into an infinite swr without damage to its finals.

Frequency coverage on the various bands includes a generous 40-kHz overrun at the top and bottom edges of each band, whose limits are: 1.8-2.3, 3.5-4.0, 7.0-7.5, 10.0-10.5, 14.0-14.5, 18.0-18.5, 21.0-21.5, 24.0-24.5, and 28-30 MHz. The heart of the frequency-determining circuit is a permeability-tuned oscillator operating in the 5.0-5.5-MHz range. Note that phase-locked-loop circuits were purposely not used in order to provide better receiver performance.

Stability of the vfo (PTO) is less than 15-Hz change per degree F over a 40-degree change from 70-110° F after 30 minutes warm-up, and less than 10-Hz change between 105 and 125 volts ac using the Ten-Tec 18-Amp supply. The tuning is vernier and gives approximately 100 kHz per full revolution of the dial skirt and about 18 kHz for one full revolution of the knob. Readout is direct with +/− 100-Hz accuracy in 0.3"-tall numerals. The last numeral is green while the first five are red.

The transceiver contains one LSI, 20 ICs, 94 transistors, 107 diodes, and six LED readouts on 22 PC assemblies with plug-in cables. Its construction is a rigid steel chassis with dark-painted, textured aluminum panels and a snap-up steel tilt bail. Dimensions are: 5¼" H × 15" W × 14" D (including the massive heat sink). Weight is 14 pounds. The rig requires 12-14 volts dc for operation, at 850 mA in the receive mode and 18.5 A maximum in the transmit mode.

Receiver

The receiver is a triple-conversion superhet having a sensitivity of 0.25 microvolts for a 10-dB signal-plus-noise-to-noise ratio on all bands and 0.8 microvolts typical with the rf preamplifier switched off. It is interesteing to note that the preamplifier circuit attenuates incoming signals by being switched out of the circuit (giving 10 dB of attenuation) and by inserting 10 dB of resistive attenuation in series with the antenna lead and input, for a total of 20 dB of signal attenuation. The dynamic range is better than 90 dB with a third-order intercept point of +15 dBm. Selectivity is obtained through 12-pole crystal filtering in the i-f circuits (consisting of 8-pole and 4-pole filters in series) instead of the more usual 8-pole filters, resulting in a nominal SSB bandwidth of 2.4 kHz and a 1.7:1 shape factor between the 6-dB and 60-dB down points on the selectivity curve. Optional 250-Hz, 500-Hz, and 1.8-kHz filters were installed in the unit sent for test by *73*'s staff. If desired, an optional 8-pole filter may be substituted for the standard 4-pole filter (giving 16 poles, cascaded) to provide nearly ideal steep-sided skirts on the selectivity curve and an even better shape factor. A notch filter is also provided for attenuating interfering signals by a *minimum* of 50 dB and is tunable between 200 Hz and 3.5 kHz, which means that you can notch out annoying heterodynes within the audible range and obtain vastly improved reception. This is particularly useful on SSB, but is very successful on CW as well. A CW "spotting" tone of 750 Hz is also provided for zero-beating a received signal. This is done by tone-matching instead of zero-beating; that is, when the "spot" tone matches the received tone, you are exactly zero-beat with the desired signal. Incidentally, this system is much more accurate than the null, or zero-beat, method, because the latter method could introduce an error of at least 200 Hz since the audio response of the circuits cuts off at about 200 Hz.

I-f frequencies are 9 MHz and 6.3 MHz, and the PTO covers 5.0-5.5 MHz. Audio output up to 1 Watt with less than 2% distortion (reference to 8 Ohms) can be selected. Spurious responses are all below the equivalent 10-dB S+N/N ratio except at 1.838 MHz (where the equivalent 15-dB S+N/N ratio applies), at 21.300 MHz (where the equivalent 20-dB S+N/N ratio applies), and at 28.980 MHz, where the "birdie" can be eliminated by tuning to the next higher band segment (29.0-29.5 MHz) and tuning 20 kHz below the lower band edge. Although the birdies are detectable, they were not objectionable in our evaluation and could be heard only under quiet band conditions. There is an adjustable noise blanker whose threshold may be varied by rotating a small knob on the front panel. I-f rejection is greater than 60 dB.

The S-meter is factory set to provide an S-9 indication at a signal input level to the antenna terminal of 50 microvolts. Each transceiver is supplied with its own performance specifications as measured in the laboratory before shipment. In the case of the one tested by *73*, S-9 was obtained with an input signal of 47 microvolts at the antenna terminals.

The antenna input is low impedance (nominal 50 Ohms), unbalanced to ground. The dynamic range is given as 90 dB nominal, and the *73* test transceiver was measured in the laboratory before shipment (see box). Offset tuning is provided in two ranges: a low range of +/−500 Hz and a high range of +/−4

Measured performance of the Ten-Tec Corsair transceiver tested by 73.

kHz. This feature is particularly useful for netting (low range) or for DXing where the foreign station listens up or down by several kHz.

Transmitter

The transmitter dc power input is 200 Watts maximum at 14 volts dc (CW and SSB) and a 100% duty cycle of up to 20 minutes is permitted without exceeding the temperature limitation as measured on the final amplifier heat sink. Operation in excess of this limitation should only be undertaken by force-cooling the heat sink with a small fan (not supplied). Rf power output is 85-100 Watts typical into a resistive load, and each transmitter is measured on all bands prior to shipment (see box). Output impedance is nominally 50 Ohms, unbalanced to ground, through a UHF-type connector. The microphone input, although nominally high impedance, will accept either Hi-Z or Lo-Z microphones with 5-millivolt output. An optional electret microphone may be obtained from Ten-Tec. Polarizing voltage is available on pin 4 of the connector for microphones such as the electret sent with the unit for *73*'s evaluation.

T/R switching is by VOX or PTT on SSB and instant or semi-break-in on CW. The CW sidetone is internally generated, and its pitch and volume (which is independent of the receiver's audio control) may be adjusted to suit the operator by means of two thumbwheel controls inside the rig and reachable through a hole in the bottom of the metal cover near the tilt bail. The CW sidetone operates only in the CW mode.

SSB generation is by means of a four-pole crystal-lattice filter at 9 MHz, using the balanced modulator system of carrier suppression which is typically 60 dB (see box). Unwanted sideband suppression exceeds 45 dB with a 1.5-kHz tone input (see box). Spurious output is better than −45 dB relative to full output of the transmitter.

The panel meter is switchable to read several functions: forward (output) power, collector current (Ic), vswr, and speech processor level. These functions are selected by a front-panel switch near the meter.

CW offset is 750 Hz, automatically provided, and ALC is front-panel adjustable between 30 and 100 Watts output. An LED indicator flashes at the ALC threshold as drive is increased or as modulation peaks reach a preset level.

Observations on Use of the Operating Controls and Accessory Features

OFFSET tuning is similar in function to the receiver incremental tuning offered on most modern transceivers, except that this one has a dual range selectable by a toggle switch on the front panel plus the fact that the receiver, the transmitter, or both at once may be varied by this control through switch selection. . . particularly useful for net operation and for working DX.

Passband tuning adjusts the position of the second i-f crystal filter in relation to the fixed first i-f filter. When the filter selected by the XTAL switch is wide (2.4 or 1.8 kHz), the PBT control becomes essentially a variable bandwidth control whereby counterclockwise rotation reduces the bandwidth on the low side of the selectivity curve, and clockwise rotation reduces the bandwidth of the high side of the selectivity curve. When the XTAL switch selects a narrow filter (500 or 250 Hz), the PBT control is used in the normal passband tuning sense. The Ten-Tec PBT circuit produces the effect of varying the bfo, changing the pitch of signals passing through the narrow filter to separate signals that are very close together. For example, on RTTY, the passband tuning can be adjusted to pass only the 2295- and 2125-Hz tones for superior rejection of adjacent signals.

VOX/OSK depends upon the mode of operation selected (SSB or CW) and the position of a front-panel switch. For example, in the SSB mode, if you select the VOX position, normal VOX operation is achieved and VOX gain, VOX delay, and anti-VOX controls are effective to tailor it to your own preferred style. If you select the FAST position, you have PTT operation with fast recovery. If you select the SLOW position, you also have PTT operation but with slow recovery from the microphone switch. In the CW mode, however, the VOX is inoperative and T/R switching is accomplished by the break-in keying circuits. In this mode, FAST gives you full break-in keying, while SLOW permits semi-break-in keying.

AGC switching is provided so that the hang time, i.e., receiver recovery time, may be selected to suit the operator. In the OFF position, there is no auto gain control, and i-f gain is controlled by the rf gain control.

Noise blanker level is adjustable and sets the blanking threshold. In the fully counterclockwise position, the blanker is off. Clockwise rotation of the control increases blanker sensitivity, permits fine adjustment, and prevents overloading, ensuring the best possible fidelity of the received signal.

The DRIVE control adjusts both the microphone gain and CW level.

The ALC control sets the threshold level at which automatic level control starts. When rotated fully clockwise, the input power is factory-adjusted for 200 Watts on the least efficient band when the ALC LED indicator just starts to blink. Power can be reduced below this level to approximately 30 Watts by rotating the control fully counterclockwise. A change in the ALC control adjustment requires a change in the DRIVE setting.

You can use either high- or low-impedance earphones with the Ten-Tec Corsair, and the equalizing audio circuit is such that the audio amplifier operates at its best signal-to-noise ratio at all times.

WWV is received at 10 MHz. Set the LED frequency readout at 10.000 with the bandswitch and tuning knob. Set the switch for selectivity at position 3 (2.4 kHz) and zero-beat WWV's carrier. If the LED frequency display does not read exactly 10.000/0, you may adjust the timebase oscillator internally to read the exact frequency at zero beat.

The rear panel of the Corsair contains some interesting features that will make operation of the rig and accessories more convenient and will permit great versatility. Before looking at the back-panel features, we should have a look at some interesting front-panel provisions that may at first seem a bit confusing.

The RF-POWER dual-function control contains a push-pull switch which turns the rig on and off (in = on; out = off). Rotation of the control varies the gain by changing the bias to the i-f amplifiers. This is the rf-gain control and on-off switch.

As you might expect, the input level to the audio amplifier of the receiver is controlled by the AF-RF AMP knob, but it also has a push-pull switch connected to the control which activates the rf amplifier of the Corsair. The LED lights when the control is pushed in, telling you that the rf amplifier is operative. When the switch is pulled out, a 10-dB attenuator is switched into the circuit and the 10-dB-gain rf amplifier is disconnected entirely. The effect is a 20-dB reduction in signal applied to the rf mixer stage, which results in improved dynamic range and better sensitivity than would be possible if only an attenuator were used. Superior operation in the QSK or VOX modes can be obtained by temporarily setting the rf control fully clockwise, and then adjusting the setting (while receiving a strong station at about S7 or better) to a level slightly higher than desired. Then reduce the level of that signal by means of the rf control to a comfortable level. In this way, only one setting of the AF-RF power control need be made, and agc pumping and intercharacter signal blasting when QRM is present may be avoided when operating CW.

Rear-Panel Features

The EXT T/R jack is intended to actuate a high-power linear amplifier and is derived from a set of normally-open contacts on the auxiliary relay located on the control board. When operating CW, a thumb potentiometer located on the control board controls the drop-out delay of the relay, but in SSB, the drop-out delay function is switched out of the circuit. Adjustment should be made to suit the individual station requirements only *after* external equipment is installed and must be controlled by this relay.

Obviously, the key or keyer plug is inserted in the KEY jack. Keyers designed for negative-line keying, i.e., grid-block keying, will not work. The key line is positive and is a high-impedance circuit requiring very little current for actuation.

Two AUX 12 VDC jacks are provided, either of which may be used to power external equipment such as an external vfo or keyer. The jacks are connected to the +12-V-dc line *after* the protective fuse, which is rated at 20 Amperes.

A nine-pin female connector (ACCESSORIES) is available for interfacing an external vfo. When the vfo is not used, an external jumper must be used and the rig is shipped with the jumper in place.

The LINEAR socket consists of a 12-pin female connector which enables front-panel bandswitching of a linear amplifier or antenna relays. Nine band positions correspond to nine switch terminals, while three additional terminals are intended for a common, a ground, and a T terminal.

AUDIO IN-OUT jacks provide connections to the microphone and speaker for attachment of a phone patch or a RTTY unit. AUDIO OUT may also be used for connecting an external speaker *without* disabling the internal speaker.

A RECEIVE ANTENNA jack is provided for connection of a receiving antenna to the receiver input at all times by placing the small switch nearby in the *receive* position. In the *transceive* position, the receiver input is connected to the antenna socket for normal transceiver operation.

VFO IN-OUT jacks make it possible to switch off the transceiver's internal PTO such as when using an external vfo. The Corsair is shipped with an external U-shaped jumper in these jacks, enabling the internal PTO.

The PTT jack is in parallel with the microphone switch for activating the push-to-talk line and is operable in the SSB mode *only*. This permits an external switch such as a foot switch to be used for transmit/receive control.

The EXT SPKR jack is for an external station speaker and disables the speaker of the Corsair when an external station speaker is plugged in.

Operating the Corsair Transceiver

The bottom line, of course, is how the Corsair operates. Is it smooth and easy? Is it convenient? What are the disadvantages and drawbacks, if any? What is the "feel" of the rig, an indeterminate quality that is very subjective and depends upon the operator. . . but nevertheless important.

When I first spoke with Dan Tomcik at Ten-Tec about this rig, I stressed the importance of CW in my own operating and allowed as how I expected this Ten-Tec rig to excel in that department. Dan quickly corrected my impression. . . but he didn't

tell me I was wrong. What he said was, "yes, indeed, Ten-Tec has the reputation of building CW rigs that delight the operator with their QSK features and their rock-solid signals . . . but Ten-Tec rigs also have fine SSB performance which has often been overlooked." He wanted to make sure that I knew the Corsair was a no-holds-barred, fine SSB *and* CW rig. Consequently, I was on the lookout for something above average in audio quality on both transmitting and receiving.

Now we can return to the setup in my own shack, and I have to tell a little story at this point. In their effort to send the rig to us as quickly as possible, Ten-Tec omitted the instruction manual (which, by the way, is very complete and clear with good diagrams and descriptions). I used this opportunity as an advantage to see if it would be possible to set up the rig and operate it *without* the manual. Now I realize that this is the time-honored, traditional American way to do things . . . after all else fails, read the instructions. So here I was in exactly that position, but I reasoned that the rig was designed to operate into an infinite swr without damage to the transistors and the heat sink looked big enough to cool the Hercules kilowatt, so I wasn't too worried. Therefore, I proceeded with care and carefully connected the proper plugs to their mating receptacles. Each was labeled clearly. Ground strap first, antenna connector, speaker, keyer power supply interconnection (yep, switch was off), and finally, I plugged it into the ac outlet in my shack wall. The moment of truth was about to arrive; switch on and what do you know—signals, loud and clear, coming fom the neat compression-loaded speaker!

I first checked the band edges on receive and checked the calibration against WWV . . . perfect. Then I adjusted the controls for CW reception and checked the filters—very nice! Next, I tried the various other controls, including notch filter, offset tuning, passband tuning, and the various gain controls. Do you detect a bit of delay here, sort of a putting off of the ultimate test? Well, you're right. The manual was missing, and I didn't want to blow the rig by inadvertently doing a no-no. I needn't have worried.

From previous Ten-Tec rigs I knew that the LOCK position of the control is the tune-up position, so I selected LOCK and slowly advanced the DRIVE control with the meter reading FWD, or forward power. The needle obediently came up and my antenna seemed to be taking the load nicely. As received from the factory, the ALC control had been set fully clockwise. Not realizing that this was the normal full-output position, I backed it off to minimum, or maximum counterclockwise position, wondering why I could not obtain full-rated output (and input). By bringing the ALC up slowly, I found the reason that it had been set fully clockwise in the first place. It provides a limited variable adjustment of output power.

From that point on, contacts were quick and simple. Everyone commented on the keying quality and the solid signals, and I particularly enjoyed full QSK, in spite of some QRM close to the frequency. By appropriate adjustment of the rf gain, I was able to minimize its effect, and a tweak of the NOTCH and PBT knobs solved the problem. Many contacts later I decided that the Corsair was some nice rig. I had used it on 160, 80, 40, 30, 20, 15, and 10 meters . . . all with good signal strength and quality reports.

"But what about SSB," you ask? Wait a minute; I am coming to that! I hadn't requested a microphone with the rig so one wasn't sent. A stupid oversight on my part, so I scrounged around the shack and workshop for a mike that would work. Aha! Found one. Oh, oh . . . no four-pin connector anywhere. SSB would have to wait until another day.

For the next three days (and nights), I burned up the bands with this Corsair, getting to know it better and better. I found the more I used it, the better I liked it.

Finally, the manual and microphone arrived, and I was relieved to see that I had done everything right according to the book. In fact, I guess I had been a bit conservative. Now to check it out on SSB.

Evening operation with a vertical antenna on 40-meter SSB is not conducive to your average quiet QSO. The band was alive with foreign broadcasts, but I managed one or two QSOs using the processor to keep average voice power up. Incidentally, if you use the processor according to the manual, you will get *very* complimentary reports! I got some unsolicited praise for "excellent and natural voice quality," "lots of punch," "nice, narrow signal," "didn't know you were using a processor," and the like.

Next, I ran some DX on 15 meters with essentially the same reports. Much praise and no objections of any kind. Well, why not try it on 20? Isn't that the ultimate test for low power and modest antennas? So, I did . . . and results were the same. "Your audio is smooth," "Broadcast quality," "unusual for a sideband rig," etc. I got the same kind of reports on 160: "Mellow . . . nice, easy listening."

What more can be said? I like the Corsair and, for once, I felt completely comfortable (well . . . almost) on SSB; for me, that's quite an admission. Naturally, I expected to be happy with CW, and I was. The reports have been uniformly complimentary, and just this evening I worked a Colorado station on 15 meters who told me (in an *unsolicited* report, mind you) that he had looked at the keying waveform on his scope and it was *perfect!*

Here's another thing, too, that may be of importance to you: The Corsair is roomy inside. Things are well laid out and spaced for service. You don't feel crowded, and you have the confidence in your own ability to remove and replace a PC board, for example, if it is ever needed. Here is another Ten-Tec plus: SERVICE. That is intentionally capitalized, too. I had a problem with a Century 21 a few years ago and called Ten-Tec's service department. They helped me troubleshoot the cause over the phone, asked me to mail the board with its defective component back to them, and put a new board in the mail on the day of my call! You can't beat that—anywhere. With Ten-Tec you have a feeling that you would *like* to do your own servicing, and that's a new feeling for most of us with other rigs. Sure, they could have made it smaller, but why should they? This way, it's very neat and open and still of a reasonable size for desk or den. The rig is fully warrantied for one year, and the transistor finals are warrantied for five years on a *pro rata* basis!

Okay, you've heard the favorable impressions. What about the *bad* things, you ask? Well, there are a couple of things that aren't bad, but could be improved upon . . . and probably will be. They aren't serious, and might not even bother someone else—you, for example. But for the record, here they are.

There is no frequency memory. That is, there is no extra on-board selectable frequency that can be stored until needed. Frankly, I admit being lazy and have become used to some of the newer rigs with their keypad memory entry and recovery. I also missed the dual on-board vfo's provided by some of the rigs. This is convenient, and although not a requirement, sure is handy. Ten-Tec provides an optional external vfo for connection to the Corsair, and up until a few years ago, that would have been the epitome of luxury. Today, it's okay, but not state-of-the-art. Nevertheless, the DX operator will want his external vfo for split-band operation.

Next, I do a fair amount of shortwave listening and really appreciate general coverage in a receiver. It's true that this is a communications transceiver and is not intended to have all the bells and whistles, but when you have a basic rig this good, you'd like to have it cover some of the SWL bands, too. I also missed having an AM reception position on the mode switch. Frankly, I don't give a hoot for transmitting AM anymore, but I do like to listen to BBC or Deutsche Welle occasionally without having to zero-beat their carriers to recover audio. Nit-picking, sure; I know.

Finally and most bothersome to me was an essential feature that did not meet my expectations: the tuning vernier. It felt rubbery and I think it has a teeny bit of backlash. It left me with the impression that it might creep after being set on a frequency. It turns a tad easier clockwise than it does counterclockwise, so I checked with the boys at Ten-Tec and they tell me this is easily corrected by a dial adjustment . . . it's purely mechanical and the function of alignment during assembly. Great! I'm happy to hear that this isn't the way all Corsairs behave. Yours will probably be perfect in this respect. The only reason I noticed it is that some of the comtemporary rigs have such silky-smooth tuning that one quickly comes to expect it in *all* rigs. In possible defense of dial friction is the undeniable fact that it isn't as easily knocked off frequency or inadvertently shifted. However, a dial lock is the solution to that problem.

In summary, while the Corsair lacks a few bells and whistles, it sure has *performance* aplenty.

The suggested retail price at $1169 is ballpark for a rig that has all these good points; the external power supply is available at $199 for the deluxe model with a front-radiating speaker and $169 for the utility supply without speaker. If you want more than the nominal 2.4-kHz selectivity, you will have to specify extra crystal filters when ordering your Corsair. These are available for 1.8 kHz (SSB) and 500 and 250 Hz (CW and RTTY). They all fit into the rig and can be selected when needed. This is an improvement over some of the newer rigs where you have to choose only one of the three for use in addition to the standard one supplied. Many hams don't need and wouldn't want the narrow filters anyway, so it's logical to offer them as options.

All in all, I like the Corsair and would probably be happy with it in my shack as an only transceiver. When it comes to sheer operating ability, the Corsair will probably hold its own against anything available today. It's rugged, honest, easy to use, and nice to look at . . . besides which it sounds great on the air. Its sensitivity, selectivity, dynamic range, and resistance to front-end overload are superior . . . and it stays put on the frequency of your choice.

Whether or not the Corsair is your cup of tea depends on what you rate as desirable features and what you like in a rig . . . but after all, that's what makes horse races and amateur radio fascinating.

DOVETRON'S WIDGET

In this era of expensive, state-of-the-art rigs and microprocessor-controlled transceivers, there is still room for useful gadgets. Dovetron has recognized this largely unsatisfied need with the introduction of a new, simple gadget, appropriately named the Widget.

The Widget is designed to alleviate one problem which has accompanied the increasing miniaturization of 2-meter transceivers—that of low-quality audio reproduction. When so much is compressed into a small space, there is little room left for the speaker, and it is usually placed in a position better suited for the heater fan to hear than the driver. However, with the Widget, you can listen to your 2-meter radio through the in-dash AM radio and benefit from the higher fidelity as well as the larger speaker size and better placement.

The Widget takes the receive audio output of your transceiver and retransmits it at the low end of the broadcast band. You then tune your radio to the appropriate frequency and capture the low-power signal.

Connection of the Widget is simple—you just plug it into the external speaker jack of your mobile rig and unwind the enclosed wire antenna to ensure good pickup. The cable included with the Widget has a subminiature plug on one end, which is standard for most mobile radios. The antenna is not always necessary, and it can be unplugged from the back of the device. I found that with my mobile installation, the transceiver and the radio were close enough that I did not need the antenna. No power connection is necessary; the Widget rectifies part of the incoming audio to power the circuit.

The circuit is housed in a small (about 2 by 1 by ½ inches) sturdy black box with an LED on one end. The LED signifies that the Widget is receiving a signal and indicates the relative signal level. The box is made of high-temperature plastic designed for year-round exposure in an automobile, and the PC board is made of epoxy-glass FR4. It includes an audio high-pass filter to limit the bass characteristics; the tone may also be controlled by the AM radio.

But why let the uses of the Widget stop with that? The circuitry can be powered by miniscule audio output, so use with a handie-talkie is feasible. If your handie-talkie also doubles as a mobile rig, the Widget will make marginal contacts much easier.

With the antenna fully extended, I found that the Widget has a range of 40 or 50 feet, which gives it some usefulness around the home. You could hook it up to the HF rig and use a cheap portable radio to monitor the frequency, or connect it to the television set for remote listening. By hooking up the Widget to a high-fidelity AM receiver, it could also be used to improve the audio quality of small tape recorders or other portable radios.

Unfortunately, the Widget is crystal-controlled, which gives it good stability but prevents the transmitter frequency from being moved to avoid interference from the commercial broadcast stations. I encountered this problem in the Boston area, where there is a station located near 530 kHz. This is the Widget's transmit frequency. Although the station was not directly on 530 kHz, my radio, like many other car radios, lacked the selectivity to reject the nearby station. Thus, the relatively low signal of the Widget was overrun by the station, making it unusable on that frequency.

However, the second and third harmonics, at 1060 and 1590 kHz, respectively, are also available at a slightly lower power level. In my case, the signal was strong enough to use one of the harmonics.

According to the specifications, the unit has a life expectancy of about 10 years. In addition, the nature of the Widget prevents it from becoming outdated—unlike a transceiver, small gadgets do not have to be state of the art. It comes with a 30-day warranty and may be repaired for a nominal fee within 90 days.

RTTY CALLBOOKS

For anyone interested in RTTY, here are two books which are indispensable—*The World Wide Radioteletype Call Sign List* and *World Wide Radioteletype Stations in Frequency Order.* These books provide a vast amount of RTTY information in a minimum of space, and they have been designed for easy access and cross-referencing.

The RTTY station frequency list has 2,198 listings, a number which is continuously growing, according to the book's publisher Thomas Harrington W8OMV. Harrington collects his information from a variety of sources, including the ITU, the RTTY services themselves, and two dozen listeners he has stationed worldwide.

The book lists stations from 3 to 30 MHz in ascending frequency order. In addition to the frequency and callsign of the station, Harrington has included the station's location, the service it represents (if known), and any other information he has been able to collect. If the baud rate differs from the standard 50 baud, the different rate is noted.

The type of traffic each station handles is also noted. This will range from test slips such as "ry" or "the quick brown fox jumps over the lazy dog" to military traffic and weather bulletins.

Harmonic emissions of identified stations are listed as such, and their fundamental frequencies are also given. Harrington has included unofficial stations, those with callsigns not approved by the ITU, and other apparently underground transmissions. With each of these listings, the date a transmission from the station was last heard is given, as well as any other information obtained.

The language each station is transmitting is also identified, including Serbo-Croation. Similarly, stations transmitting in the Cyrillic alphabet or third-shift Cyrillic alphabet are also identified.

The back of the book contains a list of press service frequencies by country, service, and frequency. Another appendix lists stations transmitting meteorological data, and a third gives utility stations abbreviations and mnemonics.

The callsign list, although smaller than the frequency list, contains about 4,000 entries. In addition to the callsign, each entry includes the location and service of the station. Appendices offer further information, from a partial reproduction of ITU rules relating to station identification to a list of service and country abbreviations.

Not only does this book cover RTTY stations, but also it includes CW, weather, and satellite stations as well.

The callsign book provides a useful conjunct to the frequency list, in addition to carrying information not contained in the other book. It is especially useful because stations do not always remain on their posted frequencies, and the call letter book provides a rapid means of identifying them.

To facilitate merging these lists with additional information garnered by the user, neither book has been bound. Both lists are held together with staples, so the pages may be easily separated and placed into a loose-leaf binder or other notebook.

The amount of information contained in these books, as well as the amount of information transfer which they represent, is nothing short of fantastic. I did not realize until I began to peruse the lists how much information is accessible to the ham or SWL equipped with RTTY and a general-coverage receiver.

Imagine listening to weather bulletins from Kuwait, or military messages from El Salvadoran forces. Although the transmissions may be encoded or otherwise untranslatable, the material is available for your study.

The press frequencies listed would also appear to be an extremely valuable tool. A vast amount of filtering occurs in the world's newsgathering forces as the day's events are distilled into a half-hour newscast or a few columns of print. By tuning in the press frequencies, you can catch much of the news before it has become victim to the filtering process.

You need not worry about the information becoming very far out of date, either. Harrington updates his material three times a year in supplements to the main list. All of the entries have been positively verified before they can be listed in the books. Harrington's stringent requirements include verification of the station's existence by the station itself, by the ITU, or by three reports of the station from different sources or at different times.

My surprise upon seeing these lists may be likened to the feeling I had when I turned on a ham-band radio for the first time. There's a whole new world out there waiting to be explored, and these books are the key to it.

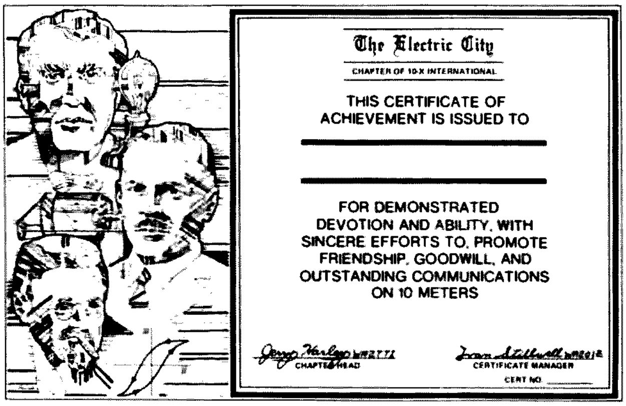
Micro-80, Inc.
2665 North Busby Road
Oak Harbor WA 98277

THE ELECTRIC CITY CHAPTER OF 10-X INTERNATIONAL

Electric City is the nickname given to Schenectady, New York, because of the numerous electrical developments generated by the Edison General Electric Company, now the General Electric Company (GE). GE was founded in 1982 by the merger of the Edison General Electric Company and the Thomas Houston Company.

The design of this award certificate is based on three of the most famous people associated with the Electric City. As you have probably already recognized, Thomas A. Edison is the top picture and Charles P. Steinmetz is the bottom picture. The center picture is of Ernst F. W. Alexanderson, who is responsible for the design of the Fessenden alternator used at Brant Rock, Massachusetts.

To go back a little, Reginald Fessenden (physicist, inventor, and radio pioneer) of the National Electric Signaling Company believed in the possibility of developing smooth and continuous flow of high-frequency vibrations, which, at the time, was impossible with the intermittent spark-gap system then in use. He envisioned the idea of superimposing the human voice on the continuous flow of high-frequency vibrations in much the same manner as



Alexander G. Bell had done on the direct current with the telephone. How to produce the high-frequency-vibration flow was the great problem. Believing that a generator might be built with this capability and being familiar with the high-frequency dynamo built by Elihu Thomson of GE, he contacted GE. In 1903 Steinmetz built a 10,000-Hertz alternator for Fessenden. The output of this alternator was a whopping 1000 Watts.

In 1904 Fessenden ordered an alternator capable of 100,000 Hertz. The order was assigned to a brilliant young engineer at GE—Ernst Alexanderson. The machine was completed and tested at 50,000 Hertz in the summer of 1906 and was delivered to Fessenden at Brant Rock. Its first demonstration deserves to go down in history as one of the great events in scientific annals. The demonstration, performed on Christmas Eve, 1906, is described as follows: Early in the evening, wireless operators on ships within a radius of several hundred miles sprang to attention as they caught the call "CQ CQ" in Morse code. Was it a ship in distress? They listened eagerly and, to their amazement, heard a human voice coming from their equipment—someone was speaking! Then, they heard a woman's voice in song. It was uncanny! Many of the operators called their officers to come and listen. Soon, the wireless rooms were crowded. Next, someone was heard reading a poem, then there was a violin solo. Then, a man made a speech, and they could understand most of the words. Finally, everyone who had heard the broadcast was asked to write to R. A. Fessenden at Brant Rock. This was how the first voice radio broadcast in history was transmitted.

Now you can understand why the Electric City chapter of 10-X International chose for their center picture a man whose picture is probably not recognized, but whose achievements in voice communications made possible the hobby and the way of life we now all enjoy.

To obtain the distinguished Electric City award, stations must accumulate a total of 50 points as well as work a minimum of three 10-X International chapters. Five points are scored for CH plus CM. C equals four points, HC plus L is three points, FS plus DX is two points, and all others are one point.

Forward a list of your contacts and be sure to include the 10-10 number for each station worked. Enclose $1.00 plus two US first-class stamps; DX stations enclose $2.00 in US funds.

For further information about this awards program or to submit an award application, address your correspondence to: Ivan Stillwell WA2OIZ, 18 Englehart Drive, Scotia NY 12302

TWO-LETTER CALL WAS

Representing the Heart of America Radio Club, Inc., out of Kansas City, Missouri, comes this Worked All States award announcement from our good friend, A. Hoogenraad WB0RAF.

To qualify for the Two-Letter Call Worked All States award, the applicant must work one two-letter callsign in each of the fifty US states. Two-letter calls would be, for example, W0RR, AK0A, KB0VL, etc. In short, any call with two or less characters in the suffix qualifies as a good contact.

To apply for this award, prepare a list of contacts in alphabetical order by state, giving the callsign, date worked, band, mode, and state. Have your list of contacts verified by two amateurs or any club secretary. Send a $2.00 (US funds only) award fee to: Adrianus Hoogenraad, 7204 E 28th Street, Kansas MO 64129.

WORKED LAEN P AWARD

The Boras Amateur Radio Society of Sweden is proud to announce the Worked All Laen P award. This award is available to licensed amateurs and SWL stations worldwide.

To be valid, all contacts must be made

on or after January 1, 1980. Applicants may utilize any band or mode; however, repeater contacts such as those made on 10-meter FM are invalid.

Scandinavian countries must work and confirm 25 different stations in Laen P Sweden. Other Europeans must work 15 different stations, while stations outside the European continent must work a minimum of five different stations in Laen P Sweden.

GCR applies. Forward your verified list of contacts to: Lars Lind SM6NT, Ekesund S-520 11, Vegby, Sweden. Enclose $2.00 (US) or ten IRCs.

THE DX LONG CHAT HAM

This award is sponsored by the Long Chat Ham Club in celebration of its sensational start. All the club members prefer a long QSO with DX stations rather than a short contact. The DX-LCHA is issued for confirming contacts with five foreign ham stations for more than fifteen minutes each.

For the award, send your application, GCR, or log, certified by a local radio club or two other amateurs, with four IRCs to: Award Manager Aki Kogure JG1UNE, Charme #303, 5-37-5 Denenchofu, Ohtaku, Tokyo 145, Japan. Be sure your application clearly indicates the beginning and ending time of each contact made.

ISLE OF EIGHT FLAGS AWARD

Representing the only location in the United States governed under eight flags, Vance LePierre W5IJU writes to share with us the Isle of Eight Flags award. As they appear on the certificate, they include France (1562-1597), Spain (1597-1735, 1748-1763, and 1783-1821), Great Britain (1736-1748 and 1763-1783), the Patriot's Flag of 1812, the Green Cross of Florida (1817), Mexico (1817), the Confederate Flag (1861-1862), and the US Flag (1821).

To qualify, the applicant must work any two stations on Amelea Island Florida on or after January 1, 1975. You may use any band or mode. Submit log data and $2.00 or eight IRCs to: Vance LePierre, 2618 McGregor Blvd., Fernandina Beach FL 32034.

JUMBUNNA AWARD

Chris Levingston VK3AOR, from Kilsyth, Australia, writes to tell us about an award dedicated to the Australian Novice.

The award requires the applicant to work and confirm a minimum of 15 VK3 Novice stations. Prepare a list of qualifying contacts in order by their callsign, giving the date, time, band, and mode of communications. Have this list verified by at least two amateurs or a radio club official. The cost of this award is $3.00 or 12 IRCs. Send your application to: Chris Levingston VK3AOR, 2 Acacia Avenue, Kilsyth, Victoria, Australia 3137.

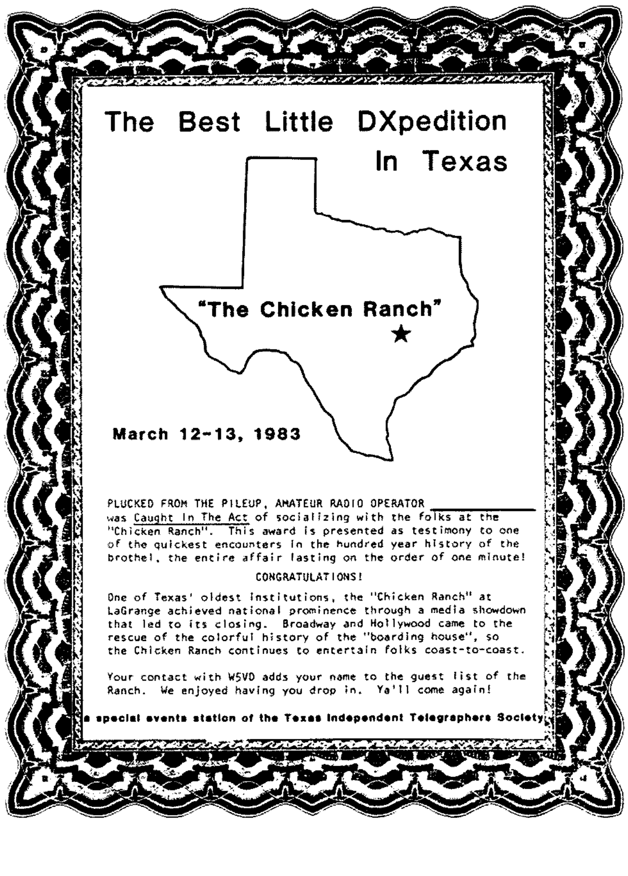
By the way, VK Novice stations are identified by the suffix N, V, P, or K. The K suffix denotes a combined Novice and limited license holder. These stations are permitted CW on 3.525-3.625 MHz, 21.125-21.200 MHz, and 28.100-28.600 MHz. They are limited to ten Watts dc of power. On SSB, Australian Novices may operate thirty Watts PEP on 3.500-3.625 MHz, 21.150-21.100 MHz, and 28.300-28.600 MHz.

THE BEST LITTLE DXPEDITION IN TEXAS

Chartered under the laws of amateur radio camaraderie and brotherhood, the Texas Independent Telegraphers Society is proud to announce the Best Little DXpedition in Texas on the weekend of March 12-13, 1983. Members and friends of the society will be operating from LaGrange, Texas, the location of the famous Chicken Ranch.

For those hams who need a peck of Texas history, the Chicken Ranch represents the oldest institution in Texas. It became a part of Texas folklore when it was exploited by a Houston newscaster who projected it into the living rooms and political backrooms of Texas. It became nationally famous when used as the setting for a Broadway musical and a Hollywood movie.

Now, radio amateurs of the world will have an opportunity to work the home of the Chicken Ranch. Using the callsign, W5VD (very distinctive), the station will operate from 1200Z March 12th until 1800Z March 13th. Depending on the band conditions and the time of day, prime frequencies will be 7.280, 14.280, and 21.380 MHz. CW frequencies will be 7.100, 14.050, and 21.100 MHz with period excursions into the Novice band. Special certificates and QSL cards will be available to those who work the Chicken Ranch special-event station. QSL to W5VD, PO Box 3225, Bryan TX 77801. Hope to pluck you from the pileup.



The Best Little DXpedition In Texas

"The Chicken Ranch"

March 12-13, 1983

PLUCKED FROM THE PILEUP, AMATEUR RADIO OPERATOR ____________
was Caught In The Act of socializing with the folks at the "Chicken Ranch". This award is presented as testimony to one of the quickest encounters in the hundred year history of the brothel, the entire affair lasting on the order of one minute!

CONGRATULATIONS!

One of Texas' oldest institutions, the "Chicken Ranch" at LaGrange achieved national prominence through a media showdown that led to its closing. Broadway and Hollywood came to the rescue of the colorful history of the "boarding house", so the Chicken Ranch continues to entertain folks coast-to-coast.

Your contact with W5VD adds your name to the guest list of the Ranch. We enjoyed having you drop in. Ya'll come again!

a special events station of the Texas Independent Telegraphers Society

SOUTHWIRE COMPANY

The Southwire Employees Amateur Radio Society (SWEARS), based in Carrollton, Georgia, announces that the second annual SWEARS anniversary special-event station will be activated on March 26, 1983, to honor the 33rd anniversary of the parent company's (Southwire Co.) first production of wire. Specially-designed QSL cards will be awarded.

Plans call for operation on 14.270 (± 10 kHz), 21.345 MHz (± 10 kHz), and 28.600 (± 10 kHz). Novices should check the first 10 kHz of the 15- and 10-meter bands. Operation will likely not be continuous on all bands, so check all frequencies. For further information, contact: Terry Martin WD4AON at (404)-832-5375.

ELMER OF THE YEAR

Francis C. Leonard W2NPT was chosen as QCWA's Northern New Jersey Chapter's "Elmer of the Year" by a committee which included such prominent local amateurs as George Diehl W2IHA, newly elected director of the Hudson Division of the ARRL, Curtis Williams W5DTR/2, section communications manager of the Northern New Jersey Section, and Joseph Painter W2BHM, head of the W2 QSL Bureau.

W2NPT, a founder and past president of the Fairlawn, New Jersey, Radio Club, has devoted most of his time for the past 20 years to helping new and would-be hams—old and young, boys and girls—obtain their tickets and get on the air. His basement ham shack continues to be a haven for hatching new ham ops.

HAM HELP

I need the service manual and schematic for a Hammarlund HQ-145 and a Galaxy V transceiver. I would prefer the original, but a copy is OK.

Henry Galbraith W9RDJ
1214 S. Alvord Blvd.
Evansville IN 47714

I am looking for RTTY software to use in conjunction with my TRS-80 model I and the Micro Modem, which I built from plans which appeared in the September, 1982, issue of *73*. Any assistance would be greatly appreciated.

William Eyter, Jr.
454 Kent Ave.
Catonsville MD 21228

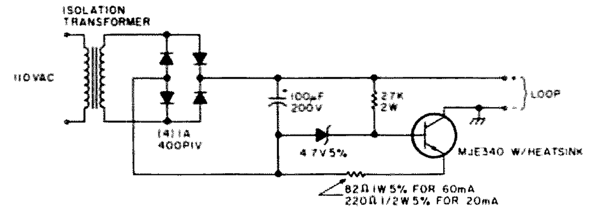
I would like to purchase a copy of the *CQ Surplus Conversion Manual* and the manual for a Hammarlund HQ-110A receiver.

Richard McCubbin WD8RQH
Box 65
Mulliken MI 48861-0065

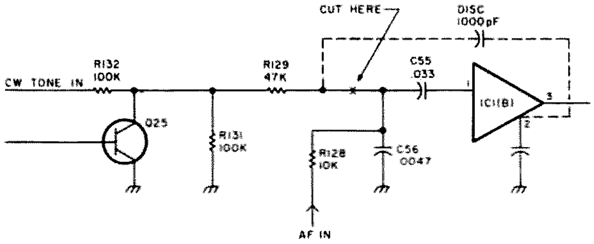
CIRCUITS

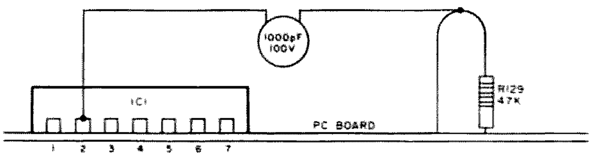
Do you have a technique, modification, or easy-to-duplicate circuit that your fellow readers might be interested in? If so, send us a concise description of it (under two pages, double-spaced) and include a clear diagram or schematic if needed.

In exchange for these technical gems, 73 offers you the choice of a book from the Radio Bookshop, *to be sent upon publication. Submit your idea (and book choice) to: Circuits, Editorial Offices, 73 Magazine, Peterborough NH 03458. Submissions not selected for publication will be returned if an SASE is enclosed.*



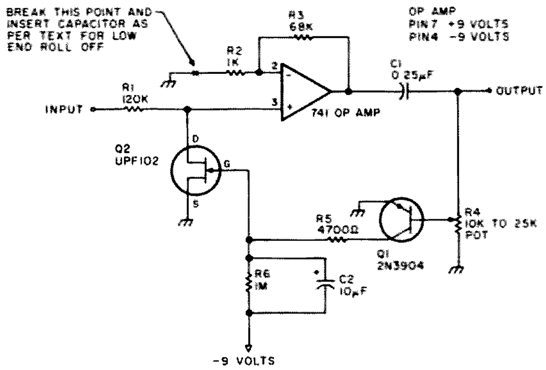
RTTY CONSTANT-CURRENT LOOP SUPPLY: This supply provides a constant 60 mA or 20 mA, regardless of the resistance in the loop. The supply's current is determined by the value of the resistor coming out of the MJE340 transistor.—Al McKenna WB6BSP, Healdsburg CA.



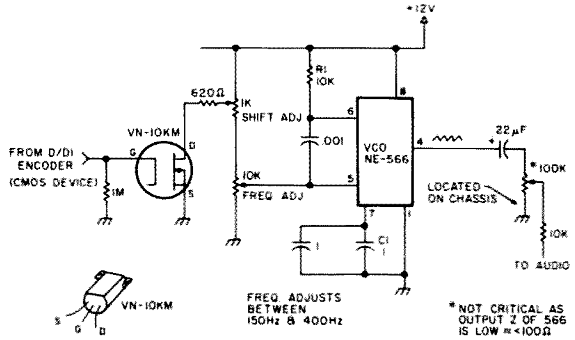


ICOM 720A CONVERSION: This simple change makes the CW sidetone volume independent of the af gain control. All you have to do is cut the top loop on R129 and solder a 1000-pF disc capacitor from R129 to pin 2 of IC1. You can reach the parts through the access cover.—Peter Wiggin ZS6ARW, Alberton, South Africa.

LOW-POWER AND RETRIGGERABLE TIMERS FROM NAND GATES: Fig. 1 shows a simple one-shot timer which is not retriggerable and, unlike some timers, is not affected by a steady signal on the trigger. This timer costs less than those using a 555, and it also has complementary inputs and outputs. The quiescent current drain is less than 100 nanoamperes, and the circuit can sink or source about 0.5 mA while operating from 3 to 15 volts. Although this circuit cannot directly drive a relay, it is useful for driving more logic. The upper limit on the time period is limited by the quality of capacitor used, with about 10 minutes being the limit for most junk-box electrolytics. Fig. 2 shows a simple retriggerable timer. The output of this one is normally a low, going high upon a low trigger. The output time will be extended each time the input is triggered low. Don't forget to tie the inputs of all unused gates to + Vcc. The values of R1 and C1 will determine the timing on both circuits. The formula 0.8RC will give an approximation of the time in seconds.—Craig Crichton K7UKW, The Dalles OR.



GENERAL-PURPOSE LIMITER: The FET is used as a variable resistor forming part of a voltage divider across the input of the 741 op amp. Q1, which is fed through the pot hanging on the output of the 741, does not begin to conduct until the negative cycles of the output reach about .6 V. The rectified voltage is applied to the FET, causing its resistance to vary with the voltage. When the circuit reaches its limit, the gain is greatly reduced. To set the circuit up, apply 20 mV of tone to the input while measuring the output. Adjust R4 until the gain just starts to drop. And to roll off the low end, put a .25-mF capacitor between R2 and ground.—Allan Joffe W3KBM, Dresher PA.



VCO-DECODER INTERFACE: This circuit matches a garage-door-opener encoder/decoder chip to an NE566 vco. It provides proper matching between the CMOS device and the vco as well as a shift adjustment. The 10k pot adjusts the frequency between 15 and 400 Hz.—William Desnoes W2HBC, Oneida NY.

AMATEUR SATELLITE NEWS

Soviet Telemetry Update

Russia's RS (Radio Sputnik) amateur satellites continue to transmit a steady stream of telemetry data. Since I last discussed RS telemetry in this column (*73*, Sept., 1982, p. 140), new interpretations of some data items have come to light. Table 1 is a revised list of the 35 RS telemetry items and the equations for decoding the raw numbers into interesting information about the spacecraft.

All RS telemetry is transmitted in Morse code at speeds from 15 to 25 words per minute. When the satellites are in range, virtually any 10-meter receiving installation should be capable of hearing the transmissions. Table 2 gives the telemetry beacon frequencies for all six of the RS satellites. It's easy—give it a try!

Thanks to *Amateur Satellite Report* for the updates.

The Home Stretch

The second half of April—probably the 21st—is now the scheduled date for the launch of the AMSAT Phase IIIB amateur satellite. If the launch takes place as planned, it will occur a little less than three years after the ill-fated attempt that sent the Phase IIIA satellite to the bottom of the Atlantic.—Jeff DeTray WB8BTH, Assistant Publisher, *73*.

Prefix	Interpretation
K	0.2 × N = output power of transponder in mW
D	N × 0.2 = voltage of main power source
O	20 × (100 − N) = charge current in mA
G	Service parameter; usually = zero (00)
U	Gas pressure of sealed system; equation unknown
S	N = temp. of voltage regulator (Celsius)
W	N = temp. of transmitter cooling fins (Celsius)
IK or SK	Same as K
ID or SD	Telemetry baseline; usually = zero (00)
IO or SO	0.2 × N = output power of beacon in mW
IG or SG	When N = 10 ± 1, a 10-dB attenuator is in line with main receiver front end
IU or SU	0.1 × (N − 10) = relative S-units, main receiver
IS or SS	0.1 × (N − 10) = relative S-units, robot receiver
IW or SW	0.1 × (N − 10) = relative S-units, command receiver
NK or RK	Same as K
ND or RD	50 × N = solar panel current in mA
NO or RO	2.7 × (N − 26) = temp. of 1st solar panel (Celsius)
NG or RG	2.7 × (N − 26) = temp. of 2nd solar panel (Celsius)
NU or RU	2.7 × (N − 26) = temp. of 3rd solar panel (Celsius)
NS or RS	0.8 × (N − 5) = temp. of structure (Celsius)
NW or RW	0.8 × (N − 5) = temp. of hermetically-sealed casing
AK or UK	Same as K
AD or UD	0.1 × N = voltage of transponder 9-volt line
AO or UO	0.1 × N = voltage of transponder 7.5-volt line
AG or UG	0.1 × N = voltage at first 9-volt stabilizer
AU or UU	0.1 × N = voltage at first 7.5-volt stabilizer
AS or US	0.1 × N = voltage at second 9-volt stabilizer
AW or UW	0.1 × N = voltage at second 7.5-volt stabilizer
MK or WK	Same as K
MD or WD	N = # of QSOs made by robot (occasionally reset to zero by ground controllers)
MO or WO	N × 0.1 = power consumption of heating system in Watts
MG or WG	N × 20 = input power of robot transmitter in mW
MU or WU	N × 20 = input power of service channel in mW
MS or WS	When N = 10 ± 1, a 10-dB attenuator is in line with the robot receiver front end
MW or WW	When N = 10 ± 1, a 10-dB attenuator is in line with the service receiver front end

Table 1. RS telemetry channel prefixes and their meanings. N is the two-digit number sent after the prefix. Where two prefixes are given, the first is used when the service (or command) channel aboard the satellite is not active. The second is used when the service channel is active, indicating the satellite is under command by ground controllers.

Satellite	Frequencies (MHz)	Satellite	Frequencies (MHz)
RS3	29.321, 29.401	RS6	29.411, 29.435
RS4	29.360, 29.403	RS7	29.341, 29.501
RS5	29.331, 29.452	RS8	29.461, 29.502

Table 2. RS beacon frequencies.

POTPOURRI

Potpourri! As our readers in F-, VY-, HH-, FS-, FR-, FM-, and FG-lands undoubtedly know, the word signifies a medley of various items. And that's what this month's Fun! is, a grab bag of questions on topics spanning the entire spectrum of amateur-radio activity. Think you're an amateur-radio renaissance man? Give this month's puzzlers a try.

ELEMENT 1—MULTIPLE CHOICE

1) From 1978 to 1979, a person claiming to be a lawyer threatened to take away all of our bands and give them to CB. Can you remember this generous chap's name and the organization he purported to represent?
  1) Richard Cooper and the Communications Attorney Service
  2) Harry Dannals and the American Radio Relay League
  3) Jon Ingram and the Citizen's Radio Coalition
  4) David Simpson and the Committee for Fair Communication

2) Remember that Jack Anderson column a few years back? You know, the one that claimed hams were controlling just about everything in Washington from the FCC to the Pentagon. Well, can you name the US Representative who gave Scoop Anderson his story?
  1) Claude Pepper of Florida
  2) Tip O'Neill of Massachusetts
  3) Elliott Levitas of Georgia
  4) Fred Richmond of New York

3) Roy Neal K6DUE hosted the films "The World of Amateur Radio" and "Moving Up to Amateur Radio." Can you name the narrator of "Ham's Wide World"?
  1) Walter Cronkite K2IBE
  2) Arthur Godfrey K4LIB
  3) Dick Van Dyke WJ6L
  4) Phil Donahue KE9UF

4) Which of the following amateurs is not a Westlink anchorman?
  1) Jim Davis KU8R
  2) Alan Kaul W6RCL
  3) Burt Hicks WB6MQV
  4) Stan Martin WA2DCS

5) A number of years ago, there was an amateur-radio column written in broken English supposedly by an oriental writer. Name the "author" and the magazine.
  1) Scratchi, in *CQ*
  2) Itchy, in *QST*
  4) Ching Chow in *Ham Radio Horizons*
  5) Hong Wouff in *73*

ELEMENT 2—TRUE-FALSE

	True	False
1) A ham was involved in the production of the movie "E.T.—The Extra Terrestrial."TM	___	___
2) The first ham to operate from orbit was Neil Armstrong aboard *Gemini 6*.	___	___
3) In 1982, the Soviet Union launched two amateur Iskra satellites from the Solyut 7 space station. The word Iskra means "peace."	___	___
4) Ken Sessions K6MVH wrote the very first book dealing with ham repeaters.	___	___
5) A famous DXer is known by the name of Dr. DX.	___	___
6) At the relatively tender age of 22, James Hendershot WA6VQP was the youngest person ever to serve as the head of a repeater coordination council.	___	___
7) Joseph Merdler N6AHU is the current president of the Personal Communications Foundation.	___	___
8) A few years back, a novel that included ham radio as an integral part of its plot not only hit the best sellers list, but also was turned into a TV movie.	___	___
9) King Juan Carlos of Spain is a ham.	___	___
10) Queen Elizabeth of England is a ham.	___	___

ELEMENT 3—SCRAMBLED WORDS

Unscramble these terms and slangs relating to ham radio.

BUST	ETADOMLU	RETME
NCTOLREEA	EKY	DNAB
KIME	CORK	GLSU
RETHE

THE ANSWERS

Element 1:
1—1 He's now believed to be living south of the border.
2—3 Still in Congress, but probably has found other ways to fish for votes.
3—2 Seems like old times just thinking about that film.
4—4 Stan's probably the missing "link."
5—5 Think ol' Scratchi ever got paid?

Element 2:
1—True Indirectly, anyway. Henry Feinberg K2SSQ designed the little alien's space communicator.
2—False As of yet, no ham has ever operated "spaceship mobile." That may change later this year, though, when Dr. Owen Garriott W5LFL is scheduled to take an HT aboard the shuttle.
3—False Spark.
4—True Not an easy question.
5—True A name given to him by Westlink's Alan Kaul.
6—True You read it here first.
7—True A much-needed and under-appreciated organization.
8—True "The French Atlantic Affair," by Ernest Lehman K6DXK.
9—True I've yet to work him, though.
10—False Not yet.

Element 3:
Stub, tolerance, mike, ether, modulate, key, rock, meter, band, slug.

Element 4:
1—DIODE, 2—POTENTIOMETER, 3—JOULE, 4—WAVEGUIDE, 5—YOKE, 8—DUPLEX, 7—STUB, 6—CARRIER, 9—FREQUENCY, 10—HAM.

SCORING

Element 1:
Five points for each correct answer.

Element 2:
Two and one-half points for each correct answer.

Element 3:
Two and one-half points for each word unscrambled.

Element 4:
Two and one-half points for each word completed.

Potpourri literally translates to "rotten pot." How rotten are you?

1-20 points—Rancid
21-40 points—Green around the gills
41-80 points—Slightly sour
61-80 points—Fresh as a daisy
81-100 points—Prime condition

Special thanks for this month's column go to Bill Pasternak WA6ITF (of *73*'s "Looking West" fame), who provided many of the trickier questions.

CORRECTIONS

Builders of the "Keyer on a Shoestring" (*73*, November, 1982, page 104) should note that the Radio Shack 276-2008 transistor specified for Q1 is no longer available. An appropriate substitute is the Radio Shack 276-2061 or Motorola MPSA42. When using these transistors, the resistor connected to the base of Q1 should be changed from 2.2k to 1k.

Jeff DeTray WB8BTH
***73* Staff**

Radio Shack recently introduced a new style of 10-uH choke which affects all of the coils in *73*'s series of Fun-Gear articles. Those articles were "The Fun-Mitter—A Goof-Proof Rf Project," Feb., 1981; "The Fun-Ceiver," July, 1981; "The Fun-Oscillator," Feb., 1982; "The Fun-Amp," May, 1982; and "Fun-Equipment Revisited," Jan., 1983.

The new Radio Shack choke can be identified by a smaller body, fewer turns (a total of 22), and the part number 273-101A. These new chokes will operate fine, provided the correct number of turns are removed. Table 1 shows the number of turns that must be removed from the full choke.

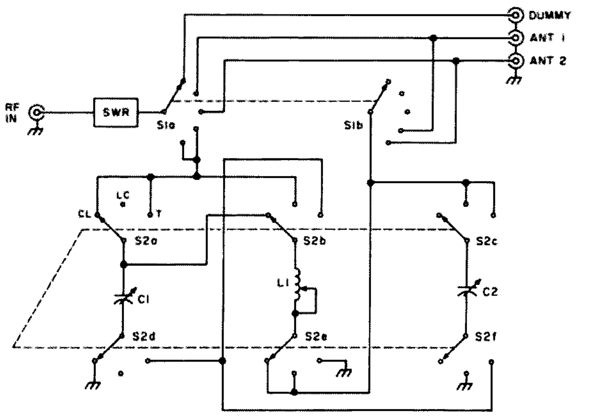
"A Tuner for Antenna Fanatics," which appeared in the November, 1982, issue, contained an incorrectly-drawn schematic. The switching system in Fig. 1 on page 42 should be wired as shown here. The only component change necessary is the substitution of a 6-pole switch for the 5-pole switch suggested in the article. Thanks to Jeff Steinkamp KA5MYF for pointing out the error.



Revised Fig. 1, "A Tuner for Antenna Fanatics."

A diagram error appeared in Fig. 3 (page 33) and Fig. 5 (page 36) of "What? Another Audio Filter Project?" in the November, 1982, issue. Both diagrams show the cathode of diode D7 connected to a 100k resistor and pin 6 of U3. However, the cathode of D7 should be connected to the junction of D6 and the 1-uF capacitor. The 100k resistor should go directly to pin 6 of U3.

4006 Winlee Road
Randallstown MD 21133

Random ruminations at the end of winter. "What do I need to do to get an article published describing my new LSI circuit that not only multiplies Q, but divides, adds, and subtracts it as well?" Boy, how many times I get that one! First of all, look critically at what you want to write about. Is it interesting to others? Bounce the idea off a few close friends; if they are friends, they won't (shouldn't) pirate your idea. If it's not technical, ask your wife (husband/mother/father/significant other) for an opinion.

If all is still okay, write up an outline for the article. Now, I don't necessarily mean the formal (I-A-1-a, etc.) outline that you learned back in the fifth grade, but rather an informal sketch of the points you want to cover. Try to organize the article with, as radical as it sounds, a beginning, a middle, and an end.

For technical articles, the first segment normally introduces what the device is, perhaps why it is needed, and general specifications. The central part of the article deals with the nuts and bolts (design and construction) phase. At the end, alignment and testing, applications, and potential other uses or pathways may be explored.

Non-technical articles follow the same train of thought, but on a parallel track. Open your idea, develop it, and close, trying to keep some sense of order. Diagrams, drawings, or photographs might occur to you as being appropriate at certain places. Note these now for later development and inclusion.

Now it's time to, as they say, flesh it out; write the words that make the whole world read, or whatever. If you have not written before or are unsure of your ability to set down words that make sense, I have a tip for you. Get a tape recorder and say what you want to write. Describe the gizmo, investigate the concept, or expand the theme *vocally*, then listen to it and write down what you said. Alternatively, type it into a word processor (my favorite technique) or write it down in longhand on a yellow pad (my second favorite technique); just get those first ideas down onto paper. You will need it in this rough form so that it can be polished into a finished gem.

Once you get the first draft down, read it. Yes, look for misspelled words and the like, but also *read it* (out loud is a good idea). Does it make sense? Are there areas which could be explained better or places where the explanation is so long-winded that it chokes the meaning to death? Clean it up, revise it (this is where a word processor makes life easy!), and when you are happy, go back to the friend you approached before and see what he or she thinks. Does your opening try to "grab" the reader? Is your last sentence a conclusion or close, or does it just end in space?

Finished? Now type up a good copy. I know we aren't all typists, but there are some standards which should be followed. Your submission copy should be typed, not handwritten, on standard 8.5" by 11" white bond paper. It should be in upper- and lowercase, be double spaced, and have generous margins on all four sides. It should *not* be uppercase-only printer output (this is a human readable article, not a program) on newsprint-weight roll paper or pasted-up sheets from a narrow thermal printer. If you have a dot-matrix printer which produces good quality upper- and lowercase print, check with the publisher before you use it; most editors would still prefer typewriter-style characters for their weary eyes.

Diagrams should be neatly drawn, with black ink on 8.5" by 11" paper. They don't have to be super-artsy; most magazines will have them redrawn by a draftsman if your article is published. Just make sure they are clear and correct. Photographs should be sharp and clear, with 8" by 10" black and whites preferred. Little Instamatic™ or Polaroid™ snaps just won't reproduce well. Color should not be used unless it is essential to the picture; most magazines cannot or will not print color photos, anyway.

Now that you've worked on this labor of love to a state of perfection, where do you send it? Here are some items to help you make up your mind. For amateur radio articles, the ARRL's journal *QST*, pays you nothing for your contribution, allowing you to bask in the glory given to those few authors whose work is published each month. On the other hand, *73* pays its authors upon acceptance of the article, with the average being perhaps $100 or more. I need not go into the number of articles published here every month.

For computer-related articles, the choice is more difficult. With the great number of specialty and general-interest magazines being published, you may well choose to direct your work to a specific audience. Payment practices vary widely, though, from reasonable amounts of cash to extending your subscription for a couple of months to a letter of thanks. To the best of my knowledge, unlike *73*, those computer magazines that pay for articles pay on *publication*, not when they accept your article. Therefore, they can, and do, hold your article for many months or years on the promise of payment. Check it out before you submit your masterpiece.

When you have decided where to send your article, wrap it in a sturdy envelope, enclose a cover letter introducing both you and your work, and mail it off first class to the magazine. You should enclose sufficient first class postage for the article's return if it is (sob) rejected; otherwise it might find its way into the editor's circular file. Then sit back and wait a couple of weeks and, who knows, your article might lead the next issue of 73!

Membrane keyboards—feh! I mentioned here a few months back that I purchased an Atari 400 computer for both the kids and some looks into the more "popular" (as opposed to my 6800) side of computers. After poking around a bit, I have reached my First Conclusion of Home Computers: Membranes may be good for a lot of things, but keyboards ain't one of them. I shall elaborate. Many of the "new breed" computers sport flat membrane keyboards rather than the more traditional typewriter-style keys. These flat panels are kidproof and less expensive to produce; they are also practically impossible to type on. Not much better are the little calculator-style button keys found on another raft of personal computers. Others' widespread frustration with this trend is evidenced by magazine articles and independent manufacturers' production of full-sized keyboards for the Atari 400, Sinclair ZX-81, Pet, and others. But if you add a $100 keyboard to an Atari 400, do you know what you get? An Atari 400 with an external keyboard. It reminds me of the time in high school when I tried to put expensive speakers on a cheap hi-fi compact. Couldn't understand why it sounded only marginally better. For the ham contemplating using a computer on RTTY or to write with, anything short of a standard (also called full-sized) keyboard is asking for trouble. No, membrane pads are fine for DTMF entry buttons, control switches on microwave ovens, or other occasional use terminals. But as keyboards designed for data entry? Feh!

Around the world with RTTY Loop brings a note here from Steve Pepler VE3KHU in Ottawa, Ontario. Steve is using a Mite teleprinter for computer output and is in need of a part. Steve, the sources I had for Mite parts dried up several years ago, and I have had no new leads since. If anyone knows of a source, drop me a line and I will let Steve and other Mite owners know about it.

Hans Granberg SM2DHG, a RTTY/computer buff from Sweden, relates his interest in the 6800 and its use on RTTY. I am sending Hans copies of old issues of RTTY Loop which may be of help in his endeavors.

This and many other letters raise another question for you all out there. Would you like to see a compilation of old RTTY Loops in book form? If so, are there any sections you would specifically like to see expanded or condensed? Please drop me a line (a postcard or QSL would be fine) with some sense of what you, the readers of this column, would like. I have been trying to work on such a tome, but I keep getting bogged down in the material. Let me know what you would like to see.

Next month, a tip of the hat to Al Jolson. Don't follow? You'll just have to wait for next month's RTTY Loop!

AMATEUR RADIO IN SOUTHERN AFRICA

What's the only country in the world which is completely surrounded by one other country and has no land below 1500 meters high? If you're up on your geographic trivia, you might be able to identify this mystery country as Lesotho, in southern Africa.

Not many people know where Lesotho is; fewer still know much about the tiny "mountain kingdom." Even the official Lesotho tourist brochures seem to be talking about a different place. These brochures are filled with photographs of the country's railroad and hotels; they mention the local TV station, the happy Basotho natives, and the rain-free climate.

What the tourist brochures do *not* mention is that Lesotho is one of the 20 least developed nations in the world. It is totally surrounded by South Africa, on which it depends for electricity, employment of the Basotho people, money from gambling at the Holiday Inn in Maseru, and food. That highly touted national railroad is less than a mile long, and half the hotels in the brochures don't really exist. It rains so seldom in Lesotho that the country must import almost all of its foodstuffs. In fact, the motto of the tiny kingdom is "Peace, Rain, Prosperity." And just because it has little rain doesn't mean the climate is perfect; Lesotho boasts the highest incidence of lightning in the world, and frequent high winds sweep dust storms across the treeless country. And that prized television broadcast with a power of only 400 mW! Can you imagine how easy it must be to cause television interference?

What the kingdom *does* have includes one of the longest reigning monarchs in the world, King Moshoeshoe II. It has majestic mountains, lots of them. The country is all mountains; even the "lowlands" are more than a mile high. And it has foreign aid. As a "non-aligned" nation, Lesotho enjoys frequent donations from other countries, including the US, France, Germany, and England. Lesotho recently received a grant of nearly 40 million dollars to fix up the nation's telephone system. There are only 4,000 phones in all of Lesotho; that's 10,000 dollars per phone!

With the highest incidence of lightning in the world, no trees to hang antennas from, a milliwatt TV station, and frequent high winds, you wouldn't think Lesotho would be an amateur-radio paradise, would you? But Rich Kingston 7P8BX (see photo) consistently receives signal reports 2 S-units louder than he gives out.

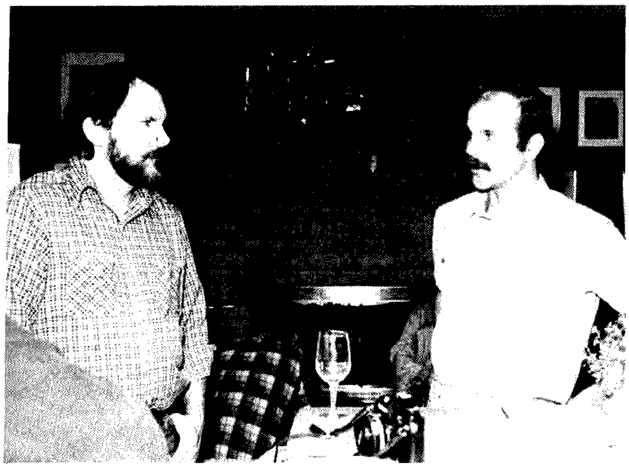
About half way along his round-the-world tour, Rich spent a few days in northern California with your DX editor. Rich offered to share his experiences as an amateur in southern Africa with *73* readers.

Rich finds amateur radio in Lesotho very successful. Using only a mobile whip, Rich and fellow Lesotho amateur Ed 7P8CG have worked stations around the world from a four-wheel-drive truck. And Rich finds no problems with his modest antenna farm of dipoles. "The other day I got on 40 SSB and worked VS6, VK, and a bunch of JAs. They couldn't believe I was barefoot into a dipole," Rich said. Rich claims the good signal reports he receives are due to strange propagation in Lesotho, but I think the 7P8 callsign is worth at least 2 S-units.

While Lesotho is not exactly rare on the amateur bands, there are many DXers still looking for their first 7P8 contact. Perhaps this information will help.

Among the more active Lesotho amateurs are 7P8s BX, CG, CL, CM, and CR. Ed 7P8CG is Vice Consul at the American Embassy in Maseru, the capital of Lesotho. Ed hopes to work DXCC on CW while in Lesotho and also can be caught working mobile. Martin 7P8CM uses a 40-meter dipole on 40 and 15 meters. A new Lesotho amateur, 7P8CR, hails from Italy and often can be heard on phone speaking Italian and Spanish. Rich himself puts his TR-44C and Swan radios on the air from his home station (7P8BX) and mobile (7P8CG). Rich hopes to supplement his existing dipole antennas with some new aerials soon, including a 15-meter beam.

Rich suggests the best time to look for 7P8 stations is early evening, Lesotho time. 1730 UTC is 7:30 pm, local time. Beginning



Rich Kingston 7P8BX, president of the Lesotho Amateur Radio Society (right), discusses schedules with Paul Hansen AE6H, president of the Redwood Empire DX Association.

about 1700 UTC, 10 meters is often open to the States. You can listen for ZS stations or the ZS 10-meter beacon to check propagation to Lesotho. 10 meters tends to fade away completely during the stateside summer, Rich explains, so try lower-frequency bands between June and August. 15 meters often opens to the States about an hour later, around 1800 UTC.

Rich says 2 IRCs or a green stamp will provide return airmail postage for your 7P8 QSL card. Rich's own QSL card (see photo) features a map of the continent, with Lesotho marked, and a colorful one-cent stamp. Lesotho, like many small countries, produces beautiful postage stamps; they add a nice touch to Rich's custom card. Rich has included on his QSL the logos from two international organizations to which he belongs: the Radio Society of Great Britain and Mensa, the high-IQ society.

Rich is also president of the newly formed Lesotho Amateur Radio Society (LARS). LARS recently held its first meeting at the home of the German ambassador to Lesotho, 7P8CI. Of the approximately 18 amateurs in Lesotho, 12 joined LARS. Only about 6 of these amateurs are active on HF, however.

At the first meeting, Rich presented the International Amateur Radio Union (IARU) films on amateur radio. Several Basotho (lifelong residents of the tiny mountain kingdom of Lesotho) attended the first meeting, but none has an amateur radio license to date.

Rich has helped bring some formal structure to amateur radio in Lesotho and has patterned the license examinations after the British model. The theory portion of the amateur examination is taken directly from the British test. The code requirement of 12 wpm is also similar to the British system. Unlike the US test, Lesotho amateurs must copy the 12-wpm code without error! No multiple choice to make it easier!

The Lesotho Amateur Radio Society has exciting plans for encouraging amateur radio activity within the country and with hams in other countries. A club station, 7P8RS, is under construction and looking for donated or loaned gear. LARS plans a Field-Day-type operation, perhaps in connection with the king's birthday. And an award for working 7P8 amateurs is in the works. About the latter, Rich says, "It won't be an easy award. Perhaps work 7P8RS and 7P8 stations on 4 bands. You'll have to try hard to earn this one."

One of the duties of a young national amateur radio society such as LARS is to set up an incoming QSL bureau for its members. The Lesotho Amateur Radio Society has started such a QSL bureau for local 7P8 amateurs. You can send your cards direct, to individual QSL managers, or to the bureau at Box 949, Maseru, Lesotho, Africa.

Any cards for 7P8 amateurs sent to the Lesotho Amateur Radio Society will arrive at LARS's PO box. The secretary or QSL manager of LARS will sort the incoming cards by callsign and hand them to appropriate LARS members at the next club meeting.

The incoming QSL bureau in the States works in much the same way, but on a much larger scale. Let's follow a card back from Rich 7P8BX to a stateside ham, KK6X.

At a club meeting, the members of LARS bundle up their stateside QSL cards without SASEs and mail them to the USA's official IARU incoming QSL bureau at ARRL headquarters. The cards are then sorted by call areas and mailed to the QSL bureaus in each amateur radio call district. The card we are following is sent to the sixth district QSL bureau in Sun Valley, California.

Here, local volunteer amateurs enter the picture, donating hundreds of hours of time to sort the many thousands of QSLs by the first letter of the suffix. KY6A, K6ANP, KB6AG, and WB6ANT would all go to the "A" letter sorter. At the next radio club meeting, the individual letter sorters pick up their shopping bags full of QSLs. Our card is sent to the "X" sorter in northern California.

Every month, the individual letter sorter gets 10-100 lbs. of QSLs to sort by individual callsign. The "X" sorter gets a break because there are no three letter suffixes beginning with X, as these callsigns are reserved for experimental licenses. With only one- and two-letter suffixes, the "X" sorter gets only a fifth of the cards the sorters of other letters receive.

At the same time as he gets our card, the "X" sorter gets any return envelopes for stations with X as the first letter of their suffix. He puts these into callsign order and adds them to the file of envelopes on hand. After he sorts the incoming QSLs, he puts each amateur's QSLs into the SASE provided by that ham. If there are enough cards in the envelope, our sorter will seal and mail the envelope, and a few days later a happy KK6X will pull his 7P8BX card out of the envelope from the bureau.

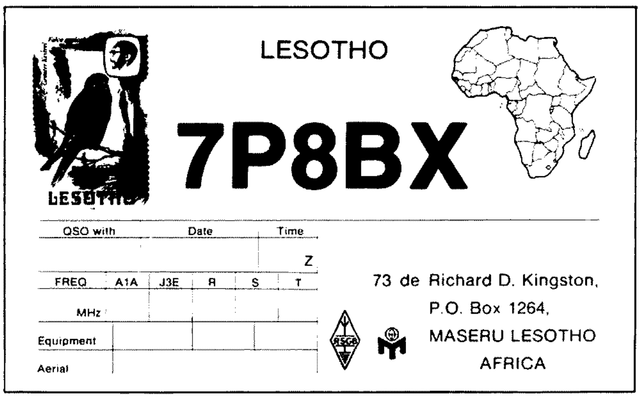
There are many potential pitfalls for the QSL card along this extended journey from Lesotho to a mailbox in California, any of which can delay delivery. The card might sit around for a while before being shipped to the sixth district bureau. It might just miss a sorting session there and not be sent off to the letter sorter for another month. That letter sorter might be forced to skip a month for various reasons. So the card could easily take six months to get across the country. If you think that's slow, think about how much you are paying for this service.

Jay W6GO (left) and Jan K6HHD O'Brien are in charge of the program at the International DX Convention at the Holiday Inn, Visalia, California, April 22-24, 1983.

The cards move through the QSL bureaus entirely by volunteer hands. The sixth district QSL bureau handled more than 600,000 cards last year! That's almost 2,000 a day, 365 days a year! The QSL bureau volunteers contribute thousands of hours of rather tedious work to make a lot of DXers happy. And you'll never guess their biggest problem: unclaimed QSLs!

Thousands of cards pile up each year for amateurs who do not have an envelope on file at the correct QSL bureau. Sometimes there are thousands for a big contest station; sometimes only one or two for a ham who "doesn't work DX." One Technician who was helping sort cards came across three for himself! One was a callsign error, but two were from South American stations worked on 6 meters, years before.

What can *you* do to speed the process and get your QSLs back as fast as you can? I suggest three things: 1) get the proper



Rich Kingston's QSL card features logos, a map of Africa, and a postage stamp for color.

envelopes or money to the bureau, 2) be patient, and 3) be patient.

You will seldom get your QSLs if you don't have an envelope or postage credits on file at your district QSL bureau. Your bureau is based on the number in your callsign, not where you live. WB2CHO/6 keeps postage credits on file at the 2nd district bureau.

Most district bureaus sell postage credits, a route often preferred by both bureau and DXer. You can find out the details of your own bureau's envelope credit system by sending an SASE to the bureau address, listed in the front pages of the *Callbook* or in *QST*. Generally, you send some money and your address, and they'll deduct postage as needed to mail your cards. When you run low, they'll note it on your return envelope.

Many bureaus prefer this method to receiving prepared envelopes, as they can buy standard envelopes in quantity, simplifying storage and reducing costs. Also, postage credits aren't outdated by a postage rate increase, and the QSL bureau finds it easier to keep the addresses and callsigns up to date with postage credits.

If you choose the envelope route, be sure to follow the bureau's suggestions for preparation of your return envelope. Get some 5" × 7½" envelopes and print your callsign *neatly* in the upper left corner. Put a single $0.20 stamp in the upper right corner and print your name and address neatly in the center of the envelope. Send a few envelopes prepared this way to your correct bureau, and wait.

Don't hold your breath. Cards can take many months or a year just to work their way through the bureau system to you. And this doesn't include the time it took *your* card to get to the DX amateur or the time it took the DX station to get around to answering your card.

In the case of the Russian stations, through Box 88, Moscow, a delay of several years is commonplace. It is not unusual to find Russian QSLs for contacts made 3-7 years ago in the bureau.

After you work a station who promises to QSL "via the bureau," you might wait six months or a year for the card. While a new DXer eagerly awaits his first bureau shipment, he can reflect on why most Honor Roll DXers are old: It takes *years* to finally get some cards. Longevity is one of the most important DX skills.

What if you have sent off envelopes or money to the bureau, worked a bunch of DX, waited a very long time, and still have nothing? Don't be afraid to drop a note to the bureau asking if you have any cards or asking them to mail any cards for you, no matter how few. Be sure to include an SASE for any reply, and be prepared to wait a few months while your envelope works its way through the system. And be nice; these are volunteers handling your cards, remember, and screaming that you have worked hundreds of DX stations and must have cards waiting won't help.

Ask politely if you have any cards waiting, and if so, would the sorter please mail them? On rare occasions, the sorter or bureau has a temporary problem, and your query might point it out. But more likely, the reason you haven't gotten anything back from the bureau is that the bureau has not received any cards for you!

Sorting the cards, putting them into the correct envelope, and mailing them takes even the "X" letter sorter a full day every month. Improper postage on envelopes costs the sorter about $4.00 of his own money every month. Why does someone contribute so much time and effort to this nearly thankless task? Well, one reason is that the letter sorter gets first peek at the incoming cards and gets to pull his own out. "That's why I volunteered to sort the 'X' cards," our sorter says. "I get mine first!"

But this is not the *only* motivation of these hard-working volunteers. Some amateurs in the Washington DC area sort cards from a different call district. They'll never see one of their own cards first. These amateurs are more motivated by the thrill they help provide. The thrill when the ham eagerly rips open the envelope from the bureau to see what treasures might lie inside.

Receiving an envelope from your QSL bureau is like receiving an invitation to a treasure hunt. For the active DXer, each envelope from the bureau will contain at least one prize, and sometimes a whole handful of new ones arrives at once. Inside that little envelope could be those long-awaited Asiatic Russians, or that South American who *swore* he would QSL via the bureau. Or it might be returns of one's own OSLs, marked "callsign unknown," or SWL cards from countries most DXers would love to work.

So some volunteers work in the QSL bureaus because they know just how eager you are for your cards and just how happy you are going to be when you open that envelope. So think of the hard-working volunteers at the QSL bureau the next time you wait for your 7P8 QSL "via buro."

NEW PRODUCTS

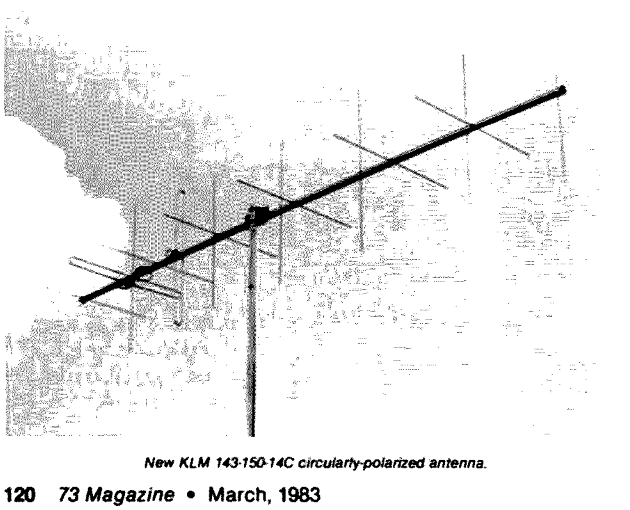
CIRCULAR SATELLITE TECHNOLOGY FROM KLM

The new KLM 143-150-14C circularly-polarized antenna not only provides optimum reception of OSCAR satellite signals, but also can dramatically improve 2-meter terrestrial communication. Linearly polarized signals (any mode, fixed or mobile) are frequently affected by buildings, mountains, and movement and, as a result, circular wavefronts develop. Reception with the 14C reduces flutter fading and multipath distortion and often improves S/N ratios. Benefits of circular polarity on transmit are similar, regardless of the polarization of the receiving antenna.

Since circularity may have a right-hand or left-hand "twist," the 14C antenna kit includes a feedpoint-mounted switcher keyed by +9 to +15 V dc right from the shack. For single feedline convenience, a special matching harness is included. If desired, the 14C can also function as two separately fed antennas, one vertical and one horizontal. Each set of feedpoints is equipped with a 2-kW balun ready for direct coax feed.

The 143-150-14C is built to provide years of reliable service. All aluminum is 6061-T6 and 6063-T832 alloys. All hardware is stainless steel except the U-bolts. The matching harness and balun coax features weather-impervious Teflon™ insulation and silver-plated conductors.

With seven elements in each plane, the 14C produces 11-dB-dc gain at better than 1.5:1 vswr. Circularity is maintained within 3 dB. Virtually unbreakable 3/16"-rod parastic elements, anchored through the 1½" boom, help reduce weight to 7½ pounds, windload to 1.2 square feet. For more information, contact *KLM Electronics, Inc., PO Box 816, Morgan Hill CA 95037; (408)-779-7363.*



New KLM 143-150-14C circularly-polarized antenna.

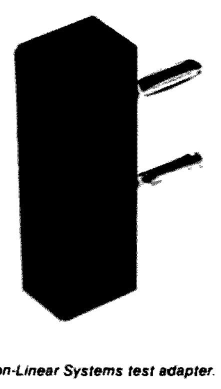
TEST ADAPTER

The new NLS Touch Test 20 test adapter for axial- and wire-lead electronic components has found a home with test engineers in test labs across the United States. Its popularity has caused Non-Linear Systems, Inc., to add this last test product to its accessory line of digital panel meter and digital test equipment line.

Measuring 1/2" by 2" by 5/8", the adapter has two slots on the side opposite the banana plus terminals, into which the leads of individual components may be inserted for component testing. The adapter eliminates the tedious task of applying prods and/or using test lead clips to make contact with the terminals of small components. Once the component leads are inserted, the testing becomes a hands-free operation, allowing for easier adjustment and control of the testing instrument. This method also eliminates the ambiguity introduced by lead or cable resistance. With banana-plug terminals 3/4" on center, the adapter can be used with any measuring instrument utilizing standard banana-plug receptacles with like separation.

This product is now available nationwide from local electronics distributors handling the NLS digital panel meter and digital equipments line of products.

For additional information, write *Non-Linear Systems, Inc., PO Box N, Del Mar CA 92014.* Reader Service number 483.



Non-Linear Systems test adapter.

NEW HAMTRONICS® CATALOG

Hamtronics, Inc., announces publication of their new 1983 catalog crammed full of goodies for the VHF/UHF/OSCAR enthusiast and two-way shops. The 36-page two-color catalog features many new products, including FM repeaters, new VHF and UHF FM receivers, helical resonator preamps and filters, low-noise receiver preamps, and a UHF receiver to listen to the space shuttle. Also included are the popular FM transmitters and power amplifiers, VHF and UHF receiving and transmitting converters, VHF transceivers, and other products Hamtronics has long been noted for.

For your free copy of this attractive new catalog (for overseas mailing, please send $2.00 or 4 IRCs), call (716)-392-9430 or write to *Hamtronics, Inc., 65F Moul Rd., Hilton NY 14468.* Reader Service number 476.

THE NEW MFJ-1440 VIDEO CONTROL CENTER

The new MFJ-1440 video control center combines enhancer, stabilizer, fader, switcher, distribution amplifier, and rf modulator to make professional-quality dubs and to give improved viewing quality of videotapes. You can make copies as good as the original, stop copyguard, improve sharpness, separate scenes, select from 4 inputs, and make 4 copies simultaneously. An rf modulator lets you monitor what you are taping or playing back on your TV set.

An Enhance control dramatically improves picture clarity, detail, sharpness, and increases contrast. You can actually see individual strands of hair and blades of grass.

An exclusive Logarithmic mode enhances light areas only for improving dark scenes.

A Noise Cancel control reduces picture noise exaggerated by enhancement.

Enhance before recording to cancel VCR and tape loss. Enhance during viewing to bring out detail and sharpness and to improve viewing of older tapes.

Enhancement can make viewing quality of 6-hour mode recordings comparable to 2-hour mode.

A bypass switch compares the enhanced with the unenhanced picture.

A Stabilizer control removes copyguard and stops picture roll and jitter. Play copy-

guarded tapes on any TV set. Duplicate any prerecorded tapes. Has stabilizer bypass switch.

The new Fader Design separates scenes, dubs out commercials, and cleans up edits and glitches for professional results. It has automatic and manual modes, simultaneous video and audio fade, continuously adjustable fade-out times, and audio dub jack for bypassing audio fade. The picture is in sync during fade.

The Video/Audio switcher adds convenience and eliminates messy cables. Select from 4 sources. (Connect VCRs, video disk, computers, games, video camera, etc.)

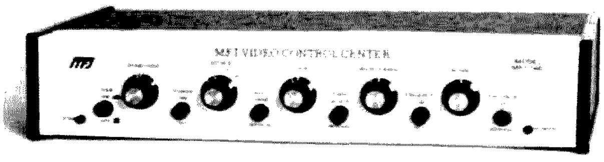
The Distribution Amplifier gives 4 video and 4 audio outputs for multiple recordings or monitoring.

The FCC-approved rf modulator converts video and audio signals to channel 3 or 4 for monitoring on your TV set.

The cabinet is eggshell white with walnut grain sides and measures 12 × 2 × 6 inches. The MFJ-1440 operates on 110 V ac or 12 V dc for portable use.

MFJ provides a 30-day money-back trial period. If you are not satisfied, you may return it for a full refund (less shipping). MFJ also provides a one-year unconditional guarantee.

For further information, contact *MFJ Enterprises, Inc., 921A Louisville Road, Starkville MS 39759.* Reader Service number 480.



The MFJ-1440 video control center.

DTMF RECEIVER KITS FROM TELTONE

Teltone announces the addition of two new DTMF receiver kits. These receivers will allow you to turn your telephone into a control device.

The TRK-927 contains the Teltone M-927 DTMF receiver and rotary dial pulse counter, a 3.58-MHz crystal, and a 40-pin DIP socket. The TRK-947 contains the M-947 DTMF receiver, a 3.58 crystal, and a 22-pin DIP socket. These units are packaged to simplify breadboarding by engineers, scientists, and hobbyists alike. Typical applications of these receivers include computer data entry, equipment monitoring and remote control, and central-office-quality DTMF-to-rotary conversion. Both kits are currently available.

For additional information, contact *Teltone Corp., PO Box 657, 10801 120th Avenue Northeast, Kirkland WA 98033; (206)-827-9626.* Reader Service number 478.

R-2000 COMMUNICATIONS RECEIVER

Trio-Kenwood has just announced the new R-2000, a highly sophisticated, all-mode communication receiver that covers 150 kHz-30 MHz in 30 bands. Designed to answer the needs of the shortwave listener as well as the radio amateur, this new radio is capable of receiving signals on AM, USB, LSB, CW, and FM. Among the more interesting features to be found on this model are digital vfo's, 10 memories that store frequency, band, and mode data, memory scan, programmable band scan, and dual 24-hour quartz clocks, with a timer that can be programmed to turn the radio on and off on a pre-selected schedule. Additional features include a built-in lithium battery memory backup (estimated 5-year life), flourescent tube digital display, 3 built-in i-f filters with switch, manual "UP/DOWN" band scan, squelch, S-meter, noise blanker, and rf step attenuator. The R-2000 operates on 100/120/220/240 V ac or may be operated on 13.8 V dc using an optional DCK-1 cable kit.

For additional information, contact your local Kenwood amateur radio dealer or write *Trio-Kenwood Communications, 1111 West Walnut Street, Compton CA 90220.*

R-2000 communications receiver from Kenwood.

CONTACT-80/MARK II SYSTEM FROM ROYAL

Royal has announced the release of the Contact-80/Mark II RTTY and Morse system for the TRS-80. The system consists of an interface unit which will link the computer to the station equipment and the necessary software on either disk or cassette.

The interface will mate with any standalone terminal unit for use as a RTTY terminal, and the interface contains its own decoder and keying circuits when used on CW. The program will send and receive RTTY at 60, 66, 75, and 100 wpm, ASCII at 110 baud, and Morse at any speed. The Morse receive mode will automatically synchronize its speed with that of the received code. The user may also change the decoding parameters to compensate for closely-spaced characters and machine-gun dots.

Contact-80 features a tri-split screen which shows received data, stored message numbers and text, and the transmitted message. The screen format may be easily changed for different uses.

The system also has MSO capability, a line printing spooler, automatic frequency monitoring, and a special mode to send and receive Basic programs.

For additional information, contact *Royal, 407 Conkle Rd., Hampton GA 30228; (404)-946-9314.* Reader Service number 477.

SOFTWARE POLLUTION CONTROL

Electrical pollution drives micro programs bananas! Power-line electrical noise, hash, and spikes often cause erratic computer operation. In addition, severe spikes from lightning or heavy machinery may damage expensive hardware.

Many systems create their own pollution! Disks and printers often create enough electrical interface to disrupt an entire program. Nearby electronic equipment is affected as well.

Electronic Specialists' recently announced Magnum Isolator is designed to control severe electrical pollution. Incorporating heavy-duty spike/surge suppression, the Magnum Isolator features four individually quad-pi filtered ac sockets. Equipment interactions are eliminated and disruptive/damaging power-line pollution is controlled. The Magnum Isolator will control pollution for an 1875-Watt load. Each socket can handle a 1000-Watt load.

The model ISO-17 Magnum Isolator eliminates severe ac power-line pollution for smooth program operation.

For additional information, contact *Electronic Specialists, Inc., 171 South Main Street, PO Box 389, Natick MA 01760; (617)-655-1532.* Reader Service number 481.

HAL'S MPT3100 SOFTWARE EXPANSION FOR THE DS3100 ASR VIDEO TERMINAL

Hal Communications Corporation has announced the MPT3100 software expansion of the popular DS3100 ASR video terminal. The MPT3100 expands the features of the mailbox option and adds a separate mode for collection, editing, and relay of multiple message texts.

The MPT3100 package will store any length of message up to 32,000 characters in any format. Each file receives a sequential serial number ID, and a directory of stored files may be accessed. The messages may be edited after they have been stored by using the MPT3100's edit mode, which includes custom identifier codes for user designs.

The relay mode allows repetitive transmission of text, and transmission order is user-set, rather than in the order the text was received. Different texts may also be grouped for retransmisson to specific geographic areas or stations.

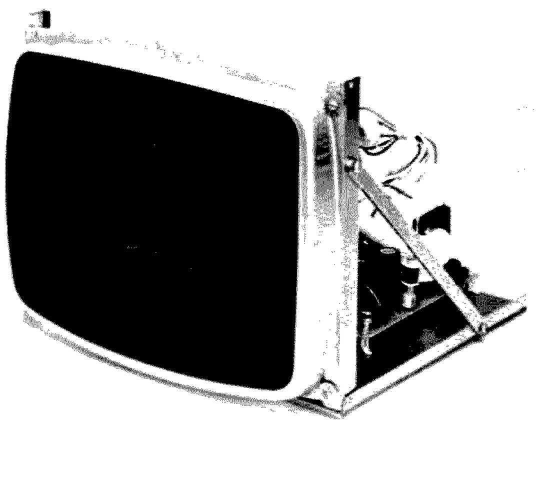
The mailbox enhancements allow the user to edit while receiving or transmitting or during a mailbox access by an outside station. Added comments have also made the directory search and SDIR listing more useful tools for the mailbox user.

For more information, contact *Hal Communications Corporation, Box 365, Urbana IL 61801; (217)-367-7373.* Reader Service number 485.

DTU-12 AMATEUR DATA DISPLAY FROM DOTRONIX

Dotronix, Inc., manufacturer of CRT displays, offers commercial-grade US-manufactured CRT displays for Morse-code translators, SSTV, ATV, or personal computer applications.

Get a clean, crisp computer-quality data display for your next ham project with a DTU-12 from Dotronix, available in kit, chassis, or chassis/ac power versions, and either P4 (white) or P31 (green) phosphor. The DTU-12 requires only 12 V at 1.5 Amps, standard TTL horizontal and vertical con-



DTU-12 display from Dotronix, Inc.

trol signals, and 2.5-V video drive. Scan rate is 15,750 Hz. Interface is through a 10-pin edge card connector.

These are brand new commercial-grade displays, factory adjusted for proper geometry and supplied with written specifications.

Dotronix, Inc., produces a complete line of compact and economical CRT displays, including 5-, 7-, 9-, 12-, 13-, 15-, and 17-inch sizes, in both chassis and kit configurations. Dotronix displays are used in the computer terminal industry, medical instrumentation, automated phototypesetting, airline flight information, and closed-circuit television applications. The company maintains sales and service operations in Minnesota, Texas, and Illinois.

For additional information, contact *Dotronix, Inc., 160 First Street SE, New Brighton MN 55112; (612)-633-1742 or (612)-633-8236.* Reader Service number 479.

CES MD22 chip.

NEW LOW-POWER DTMF MEMORY DIALER CHIP FROM CES

Communications Electronics Specialties, Inc., introduces the MD22 memory dialer chip, the only memory dialer in a single chip.

"We foresee a very broad range of applications for the MD22," CES President Ron Hankins remarks. "Its low power requirements and impressive capabilities lend it to quite a few types of communications systems." Component sales are available on the copyrighted chip, Hankins says.

No external RAM or tone generator is required with the MD22's unique design. This new proprietary chip actually operates off telephone line power due to its CMOS technology. The MD22 features a ten-year memory backup with a single lithium cell.

Other features of the MD22 include: 10- or 22-number capacity, programmable pause, manual or automatic dialing, automatic redial of the last manually dialed number, and program inhibit input to avoid memory loss.

The MD22 is programmed and operated from a standard twelve-button keypad.

CES is offering qualified users a complete dialer for installation in any standard telephone for product evaluation. For complete information, contact Ron Hankins, *CES, Inc., PO Box 507, Winter Park FL 32790; (305)-645-0474.* Reader Service number 482.

LETTERS

DISTORTED NEWS

We are Americans who have made our home in Latin America for seven years. Lately, we are seeing much distorted news about the Americas coming out of the US and would like to set the record straight for *73* readers.

When we first moved to Costa Rica—bag, baggage, grandmother, teenagers, and pets—we spoke no Spanish and knew little about the country. But, soon, our rural neighbors accepted us and graciously taught us their language, their culture, and how a city-bred family could enjoy ranch life in a foreign land. Truly, our delightful adventures there merit a book, at least!

My husband's love for the sea (Pearl Harbor survivor, retired Navy) prompted a further move, two years ago, to Colombia's Caribbean coast. We found a lovely old coconut plantation on the Pan American Highway near Santa Marta, the oldest (457 years), most fascinating city in all of the Americas.

Imagine, green palms waving in gentle ocean breezes, blue sea and sky, pounding surf and golden sand, and, towering 19,000 feet over all and snow-capped the year 'round, majestic Mount Columbus. We feel we have much . . . incomparable beauty, fine neighbors, perfect climate, a stable democratic government, and a satisfyingly-low cost of living.

Like Columbus, we have discovered a new frontier with a vast potential and, being human, are driven to tell others about our dream-come-true. If you are interested in the future of the Americas . . . and the Birds . . . write us by international airmail (35¢ a half-ounce) at PO Box 5222, Santa Marta, Colombia. It may take a while, but we promise to answer.

Now, from beautiful Santa Marta, we wish you salud (health), pesetas (wealth), amor (love), and the time to enjoy them all!

Juanita Bird
Santa Marta, Colombia

ICOM FOLLOW-UP

You may possibly recall that last June 19th I wrote to *73* to tell of my problem in trying to get some kind of response from Icom regarding a part I needed to repair a pair of Icom headphones that I have. You were kind enough to forward my letter to Icom's customer service manager, Tom Snellings. He, in turn, promised to get the part to me even if it was necessary to go to the factory for it.

As it turned out, this particular part was not available separately and Icom offered to exchange my set of phones for a new one. I naturally accepted their offer, which was more than I expected. If Icom had told me that the part was not available, I would have "jury rigged" something and would have settled for that.

What disturbed me was the complete lack of response. What I suspect happened was that some employee discarded my letters when they found that the item was not available. Of course, this is conjecture on my part, but I have that feeling.

The main purpose of this letter is to thank you and to let you know the way Icom followed up. Once again, thanks very much for your help.

Sam Zolick KB2UH
Howard Beach NY

FIST OR PHONE

Before all the stuffed shirts bury amateur radio and drive off all the young talent, how about developing a license that has either code or phone privileges or both? In other words, one can work CW on that portion of the band if one has the necessary license endorsement. You may work someone on the phone portion of the band if you have the phone endorsement. An amateur may work both modes if he or she has passed the tests for both endorsements. This is a simple solution which should satisfy everyone.

I foresee that if the "code establishment" continues to thwart some type of compromise like the one I have mentioned, then you can say "good-bye" to the recruitment of many bright young men and women into amateur radio.

Robert Baker KA1JDD
S. Yarmouth MA

THANKS TO BASH

I feel I must take exception to the editorial regarding Dick Bash and *The Final Exam* in your November, 1982, issue.

About four years ago I decided to get my General license after dutifully working my fingers to the bone for two years in the Novice bands. On advice from our local electronics store, I selected the Ameco Amateur Radio Theory Course and proceeded to study like hell for the next three months while working with the ARRL code tapes to bring my speed up to a solid 13 wpm.

In the Ameco book I took and passed every single test and when I went down to the dear old FCC, I got the surprise of my life. Although I passed the code with ease, the whole damn written test was on UHF; ergo, three months wasted. To hell with it—I quit ham radio!

I packed my TS-820 away and found another hobby (this *is* a hobby).

Per chance, about two months ago, I wandered into our local electronics store and there on the shelf was Bash—B.S., I figured, but what the hell—I bought it anyway. I dug up the ARRL code tape (why don't you pick on them?) and got my code back up and passed both with ease. I am now working on the Advanced, thanks to Dick Bash.

Since you chose to come down hard on Dick and *CQ*, I feel it is only fair for me to advise that this is the first and last *73* I will purchase. By the way, you may be interested in knowing that my former call from the 1950s was K6DDC (General class) so I am not exactly unfamiliar with amateur theory.

Scott Smith KH6JKX/HL
Kaneohe HI

P. S. Print this in your rag sheet if you want to.

Scott, lacking much in the way of letters protesting the Bash approach to licensing . . . which you endorse . . . perhaps that is the way to go. But I honestly think it is stupid to even ask anyone to bother with a written test at all under these conditions. There seems to be strong sentiment for letting in any dummy who can copy the code. So, how about it, shall we go this route and

just do away with anything but the ability to sign a name and copy code? Or is that signing the name too much to ask? Oh, about your ability to cope with the theory... the 50s?... have you opened a radio recently?—Wayne.

CW IS FUN

You keep insisting that SSB can get through every bit as well as CW. Well, this summer during a sked with AA9P, conditions deteriorated on 20m SSB, due to QRM and QSB, until I could not copy AA9P anymore. However, when we resorted to CW... Q5 copy! CW has a place.

Yes, RTTY is faster and more efficient. Yes, CW is slow. Yes, ASCII is the way to go. But I don't operate CW because I think CW is efficient or easy to receive or because of the "tradition." I like CW because it's fun. Isn't that why a lot of us got into this?

Bob Reynolds KB9MU
McHenry IL

P. S. I'm not an old-time CW op either. I'm 29 and I also enjoy SSTV and RTTY.

Yep, Bob, there are times when CW can get through... and there are times when SSB can't be beat. No emission is best all the time... as yet. I suspect that when we put our minds to it, we will be able to come up with some sort of machine-readable transmissions which will be virtually jam-proof and which will go right on through interference, static, fading, and so on. That's a good challenge. Meanwhile, I agree that CW can be fun and should be accepted because it is fun—not because there are people who want to force it on you.—Wayne.

RICH HERITAGE

Come on now, Wayne. Let's be realistic about this second language thing (*73*, November, 1982). You and I are savvy enough folks to know that the language of the ruling tribe is the language of the common little folks who live outside the castle gates. And the last thing the little guy wants is trouble with the rulers.

The language you and I speak would be a lot closer to Frisian or Dutch, were it not for the victory of some francophone Vikings at Hastings in 1066. And those same francophone Vikings might have ended up speaking a form of Gaelic, had not the Romans overrun Gaul some centuries earlier. (And had not the Gauls been chased into western Europe by the Slavs and Germanic tribes, our language would be closer to Basque—well, maybe.)

The fact remains that languages change, as do politics and economics. America is not so much a melting pot as it is a mulligan stew. By and large, we are the cultural descendants of herds of people, from Athabascan and Algonquin, through Spaniard and Anglosaxon, to Oriental and African. We are the cultural descendants of any group which has dragged or been dragged up on these shores.

These people—our cultural and linguistic forebears—deserve their rich heritage. Keeping this heritage alive in non-English-language press and media is not some heinous crime against "us." Rather, it would be far more heinous to ban these non-English media forces. The thought of banning such publications and media forces conjures up visions of some multimedia Kristallnacht. It won't hurt us at all to reach out to our fellow man, even if he doesn't speak our language as nicely as we think he should.

But this of course is a two-way street. We should indeed have a populace which speaks one language. To do that, we need to give the non-English speakers a reason to join the rest of us "anglos."

I can think of no better reason for the rest of us, who presumably speak English, to exorcise our prejudices, whether racial, sexual, religious, political, or linguistic.

Nils R. B. Young WB8IJN
New Carlisle OH

CB OR HAM?

A letter to you has been in limbo for some time now, but I just came across something which is really disgusting and an absolute insult to amateur radio.

While sitting here working on my antenna tuner and listening to the last few fading signals of 15 meters, I had an idea to drop my R4C down on 11 meters to hear what was going on. Brother, was that a mistake. Man, did I get hot!

On 27.395, at least the frequency was legal. I found a couple of CBers discussing their rigs. Let me see, Woody, in Trenton, has a Tempo transceiver, a ground-mounted vertical, and a set of "moon rakers." Harold has a ham rig that has great ears and a keyer that does great at 25 wpm! Wow, a CBer who can send and copy 25 wpm... a prime candidate for a ham ticket, right? Wrong. Come to find out, these turkeys were amateurs, I think, down on 11 with their ham rigs. Oh, yes, they did ID, naturally with their "callsigns" Mercury 5119 and Mercury 927, I believe. Come to think about it, these guys may have been doing this for a couple of years; I believe I have heard them before.

It is really sickening to hear these guys. Man, are they doing a great job of public relations for all of us amateurs in this area. To them, all we are is glorified CBers. That's the pits!

As you can probably tell, I am a new amateur. My ticket is just 6 months old and my pride has really gone to my head. It really gets my goat when I hear some of the stuff so-called amateurs are putting out on the air. They seemingly have no remorse for their behavior.

Turkeys or not, I am proud of amateur radio and of being an amateur radio operator. I will defend its principles and ideals until I am blue in the face. Just believe me though, this enthusiasm will be turned loose on these two if they keep it up!

On a lighter note, I have worked all states and 41 countries. Not bad for a mobile antenna on a balcony, is it? Thanks for listening.

Jerry Rogers KA8PTL
Monroe OH

Jerry, it is unlikely that those chaps were actually amateurs. Zillions of CBers bought ham rigs a few years ago and had them converted for 11 meters. As a matter of fact, a couple of our very large ham dealers made quite a business of making those conversions because CBers paid full list price for rigs with no questions asked while hams would do virtually anything to save $10 on the purchase... so they sold CBers first and we got what was left over. With the fading interest in HF operating, as the frequencies above the 40 CB channels were called, hams have been able to buy ham rigs again. There is still activity on the HF band, but it is a shadow of what we were hearing ten years ago. The FCC has never shown any serious interest in trying to shut down this illegal activity, so it has indeed been going for many years relatively unimpeded. There was a time when hams were screaming that these hordes of CBers were going to invade the ten-meter band, but it never really happened. I didn't think it would and said so at the time, but that was not a popular way to think then. Come to think about it, I always seem to be out of step like that.—Wayne.

EDUCATION

Here I go again, penning my second letter. Many of your ideas are echoes of my feelings, and further discussion would be redundant. Some of your ideas go contrary to my feelings, but thank goodness we are all different, and I am sure you get plenty of feedback. One topic which you hit on in your Never Say Die (Never Spend a Dollar?) column that I must respond to is education.

Your September NSD column stated, among other things, that the school system is set up so as to virtually guarantee failure as far as making any real money is concerned. How you reach this conclusion is questionable, but I have a more important querry: What can be done to change this?

My wife and I are both teachers (as well as hams). Karen works with learning-disabled children and I have a sixth-grade classroom. What are your thoughts on how to instill that desire of success with students who do not care? Any ideas would be welcomed.

The Whiteside Amateur Radio Club, which I sponsor, recently purchased your code series cassettes and the kids seem to be learning the code better than when I send it on an oscillator.

Thanks for any suggestions a teacher could use, and keep on plunking away at what you feel is right concerning amateur radio, politics, or whatever.

Carl J. Buehler WB9ZAJ
Belleville IL

Sure, Carl, whenever I discuss a problem I try to offer a solution to it. In the case of education, I noted that our colleges are geared towards training kids to work in the three proven areas for non-wealth... large corporations, government, and teaching. Once we recognize that the easiest way to make money is to be an entrepreneur, we can see the need for schools which teach kids how to be entrepreneurs. My aim is to set up a pilot-program college which will teach the fundamentals of electronics and computers, and then all of the business courses which are needed if one is going to successfully run one's own business or manage a business. In order to keep the cost down and also to provide the best possible teaching in the shortest time, the college will work hand-in-hand with a group of on-campus businesses with which the kids can get practical professional experience in advertising, sales, accounting, marketing, legal problems, production lines, technical developmental work, and so on. Between practical college courses and actually working at business, the students will be ready to go to work and be of value the day they graduate.—Wayne.

DX JUNKIES

I am calling for help as a battered, insulted, and reviled ham who has the misfortune to be "nearby DX" to hundreds of thousands of frantic thoughtless hams. At present, I seem to be the only active ham in the US Virgin Islands on CW.

It's almost impossible to keep a schedule with some old friends with dozens of hams cramming the frequency calling me. For what? The stupid endless waste of time known as 5-band DXCC. These misguided souls are frantic, like a bunch of starving junkies with their fix being my QSL card.

I have been an active ham since 1928 (W2AIS—'28-'51, KH6ARA—'51-'59, and KV4CI—'60 until the present). I am now retired and own my home, 6/10 of an acre, and a big active Labrador retreiver. I have barely enough time to keep up with domestic chores let alone reply to a flood of QSL cards.

When we were young, it took a QSL card to convince people that we really talked to the Far East or Iowa. Now, if you can't work DXCC in a few weeks, your antenna is no good.

For the past few weeks, I have endured insults, jamming, and vicious gossip. One morning, I heard a ham chide another working me by asking, "Why do you QSO that bastard? He doesn't QSL." My God! This is supposed to be a hobby, not a dogfight.

Though I had notices published in RSGB's *Radio Communication*, the JA magazine, and *CQ* telling of my intention to cease QSLing, the cards still pour in. When a ham asks me if I QSL and I tell him I don't, he will send me begging letters and homemade QSLs especially designed for my signature. Add to that dollar bills and countless IRCs. I could make a good side income on the dollar per QSL route, but that is not ham radio. Yesterday, I had to stand in line for a registered letter, and the Christmas lines are long. It was a registered, return letter from a JA ham. I added up the stamps plus the IRCs, and it exceeded $5! The worst aspect of this whole mess is what I call the "bang-bang thank you ma'am" type which is "ur 599 pse ur QSL info."

Wayne, you have clout and your editorials are read widely. Though I detest the whole QSL mess, I would cooperate by answering a "yes/no" printout for QSO claims. Why don't these crazed fanatics get together and have a master computer to handle it? God knows they spend multithousands of dollars on ham gear. Why not set up a "DX info center," hire help, buy software, and charge the applicants a yearly fee for the service? It could be done now.

If they did, the overloaded post office would be thankful and innocent victims would be relieved of the foul filth being spewed out by a deranged minority of DXaholics.

It is a timely topic for a "good Green tirade" to help these misguided souls regain some perspective as to what ham radio is meant to be—fun, not misery.

H. Miller KV4CI
St. Thomas, Virgin Islands

Sorry, OM, there is no escape from DXCC and its 5BDXCC extravaganza... plus the (dis)Honor Roll. This is an ARRL-made nightmare which makes life miserable for all hams in relatively rare DX countries. Of course, being within contact range of the entire US all of the time, you get the very worst of it. One of the reasons so many countries are rare is that the DXers drive any new ham off the bands as quickly as they can with demands that no contacts be over a few seconds long... and that the ham in the rare country devote his life to the unending pile of DXers. Even if a ham in one of these countries could work every single DXer just to get it over with, within two days he would be piled up again with chaps just piling on the heaps to prove they can get through. I'm sure we all really love the guy with the multi-kilowatt and big beam who gets a rare one and thanks him for the instant contact a few days ago... 73, OM, there is no answer to your problem that I know of. The ARRL certainly is not going to cancel DXCC just because it ruins the hobby for ops in 250 countries... and even if they did, there would be a replacement award within seconds to keep the pileups shrieking. Say, have you thought of moving to Florida?—Wayne.

Bay area's newest Amateur Radio store. New & used Amateur Radio sales & service. We feature Kenwood, ICOM, Azden, Yaesu, Ten-Tec, Santee & many more. **Shaver Radio, Inc., 1378 So. Bascom Ave., San Jose CA 95128, 998-1103.**

Smyrna GA

For your Kenwood, Yaesu, ICOM, Drake and other amateur needs, come to see us. **Britt's Two-Way Radio, 2506 N. Atlanta Rd., Smyrna GA 30080, 432-8006.**

Preston ID

Ross WB7BYZ has the Largest Stock of Amateur Gear in the Intermountain West and the Best Prices. Call me for all your ham needs. **Ross Distributing, 78 So. State, Preston ID 83263, 852-0830.**

Bloomington IL

ROHN TOWERS—Large stock plus all UNARCO ROHN items available for fast drop shipments. Wholesale prices to all users. Also wholesale distributor for **Antenna Specialists, Regency, and Wilson. Hill Radio 2503 G.E. Road Box 1405, Bloomington, IL 61701 663-2141**

Terre Haute IN

Your ham headquarters located in the heart of the midwest. **Hoosier Electronics, Inc., #9 Meadows Center, P.O. Box 3300, Terre Haute IN 478003, 238-1456.**

Littleton MA

The Reliable Ham Store Serving N.E. Full line of ICOM & Kenwood. Yaesu HTs, Drake, Daiwa, B&W accessories. Curtis & Trac keyers. Larsen, Hustler, Telex/Hy-Gain products. Mirage amps., Astron P.S., Alpha Delta protectors, ARRL & Kantronics instruction aids. Whistler radar detectors. Full line of coax fittings. **TEL-COM Electronic Communications 675 Great Rd. (Rt. 119), Littleton MA 01460, 617-486-3400/3040.**

Ann Arbor MI

See us for products like Ten-Tec, R. L. Drake, DenTron and many more. Open Monday through Saturday, 0830 to 1730. WB8VGR, WB8UXO, WD8OKN and W8RP behind the counter. **Purchase Radio Supply, 327 E. Hoover Ave., Ann Arbor MI 48104, 668-8696.**

Hudson NH

New England's Distributor and Authorized Service Center for all Major Amateur Lines. **Tufts Radio Electronics, Inc., 61 Lowell Road, Hudson NH 03051, 883-5005.**

Somerset NJ

New Jersey's only factory-authorized ICOM and Yaesu distributor. Large inventory of new and used specials. Most major brands in stock. Complete service and facilities. **Radios Unlimited, 1760 Easton Avenue, P.O. Box 347, Somerset NJ 08873, 469-4599.**

Buffalo NY
WESTERN NEW YORK

Niagara Frontier's only full stocking Amateur dealer. Also Shortwave, CB, Scanners, Marine, Commercial. Operating displays featuring Kenwood and others. Towers, Antennas, Sales and Service. **DX Communications, 3214 Transit Road, West Seneca NY, 668-8873.**

Amsterdam NY
UPSTATE NEW YORK

Kenwood, ICOM, Drake, plus many other lines. Amateur Dealer for over 35 years. **Adirondack Radio Supply, Inc., 185 West Main Street, Amsterdam NY 12010, 842-8350.**

Syracuse-Rome-Utica NY

Featuring: Kenwood; Yaesu, ICOM, Drake, Ten-Tec, Swan, DenTron, Alpha, Robot, MFJ, Tempo, Astron, KLM, Hy-Gain, Mosley, Larsen, Cushcraft, Hustler, Mini Products. You won't be disappointed with equipment/service. **Radio World, Oneida County Airport-Terminal Building, Oriskany NY 13424, 736-0184.**

Columbus OH

The biggest and best Ham Store in the midwest featuring quality Kenwood products with working displays. We sell only the best. Authorized Kenwood Service. **Universal Amateur Radio Inc., 1280 Aida Dr., Reynoldsburg (Columbus) OH 43068, 866-4267.**

Scranton PA

ICOM, Bird, Cushcraft, Beckman, Fluke, Larsen, Hustler, Antenna Specialists, Astron, Avanti, Belden, W2AU/W2VS, CDE, AEA, Vibroplex, Ham-Key, CES, Amphenol, Sony, Fanon/Courier, B&W, Ameco, Shure. **LaRue Electronics, 1112 Grandview St., Scranton PA 18509, 343-2124.**

San Antonio TX

Amateur, Commercial 2-way. Selling Antenna Specialists, Avanti, Azden, Bird, Hy-Gain, Standard, Vibroplex, Midland, Henry, Cushcraft, Dielectric, Hustler, ICOM, MFJ, Nye, Shure, Cubic, Tempo, Ten-Tec and others. **Appliance & Equipment Co., Inc. 2317 Vance Jackson Road, San Antonio TX 78213, 734-7793.**

DEALERS

Your company name and message can contain up to 25 words for as little as $150 yearly (prepaid), or $15 per month (prepaid quarterly). No mention of mail-order business or area code permitted. Directory text and payment must reach us 60 days in advance of publication. For example, advertising for the May '83 issue must be in our hands by March 1st. Mail to 73 Magazine, Peterborough NH 03458. ATTN: Nancy Ciampa.

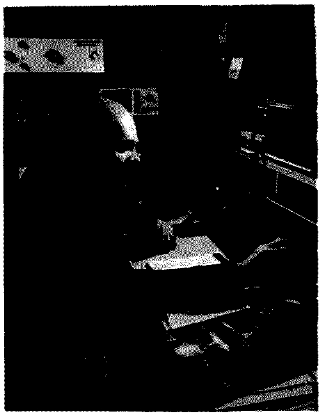
NEVER SAY DIE
editorial by Wayne Green



MY WISH BOOK

Just in case the equipment manufacturers are having any problem in figuring out what developments are needed for future rigs, I'd like to throw a few more ideas into the pot. Not that they have been very responsive to my past suggestions... which are still unfulfilled.

For instance, now that voice synthesizer chips are low in cost, isn't it about time that mobile rigs had them built in so we would know what channel we are tuned to when we change? Drivers should not have to look at the rig to see what channel has been selected. In the daytime, it is dangerous enough to have to look down at the rig as you change channels; at night, few of the rigs can be seen even if you want to.

With the increasingly lower cost of microprocessors, isn't it about time that we had some automatically self-diagnosing rigs? With today's chips, it is simple to have an extra one built in whose job is to check on the others, letting the user know if something goes out of specifications. The LCD readout on the set could then indicate the circuit out of parameter so you would know what has gone wrong.

It might be worthwhile on low-band rigs to have the screen alert the operator every now and then when the speech compressor is on. Many operators turn it on and then forget it, putting out a crummy broad signal which isn't any help on short-haul contacts. Something like that might help to clean up the DX bands noticeably.

Now that memory chips are getting so much less expensive, perhaps it's time to put in a log function which would keep track of stations contacted, times, handles, etc., and have them cross-indexed automatically. If any manufacturer is really interested in this concept, I have a surprisingly simple way for the data to be entered that would cost a good deal less than the usual alphanumeric keyboard ...and take up little space. Wouldn't you like to have a rig which would give you instantly the name of the station you are calling and when you last contacted it.

This would also be great for two-meter rigs, including HTs, so that you'd have a cross-index of calls vs. names at hand. It wouldn't take a lot of memory to keep track of a couple hundred repeater users and call their names up on demand.

That ought to keep technicians busy for awhile.

If the manufacturers are slow on the uptake on this, perhaps some readers can design the needed circuits and send 'em in for us to publish, thus doing the work for the manufacturers.

IMPORTING MILITARY TECHNOLOGY

When I wrote about a year ago suggesting that the loss of high technology to Japan could eventually result in America having new weapons designed and built for us in Japan, I got some har-de-har-har letters informing me that I was crazy. It is now revealed that US officials are interested in advanced electronics, fiber optics, laser techniques, and so on, and are looking to Japan for these.

It seems to me that until the US mounts a major program to get kids interested in science and scientific hobbies such as amateur radio, computers, and so on, we are going to continue to fall further and further behind

NO-CODE LICENSE ARRIVES

The no-code license, long a subject of hot debate in amateur circles, took a step closer to reality recently when the FCC proposed two changes in the amateur regulations. One of the Commission's proposals would allow volunteer examiners to conduct amateur tests, a change that was made possible by last fall's legislation.

The Commission suggested two possible alternatives for the no-code license. One would establish a new class of license similar to that of the Canadian Digital class, and the other would eliminate the code requirement from the Technician license.

Neither alternative would allow operation below 30 MHz, and the FCC has requested comments on which frequencies above 30 MHz the new licensees could work. It suggested conferring all amateur privileges above 144 MHz to the Experimenter class or, if the Technician class change is implemented, leaving all privileges above 50 MHz intact.

The Experimenter class test may require more extensive technical knowledge than Technicians need at present; the FCC proposed adding a fifth element to the written test which could be drawn from present test material or written specifically for the new test.

In its proposal, the Commission noted that code is seldom used in the VHF and higher bands, adding that the codeless license might serve as a springboard to higher licenses.

The FCC's proposal for volunteer examiners followed the outline of the ARRL's petition to the Commission, which calls for a three-member team to give the Technician, General, and Advanced tests. The team would be composed of a chief examiner who holds an Extra-class license and two members holding either Advanced- or Extra-class licenses.

Amateurs employed by a publisher or distributor of license study guides, as well as amateurs working for manufacturers or distributors of ham gear, would be prohibited from administering the exams.

The FCC also suggested that "umbrella" agencies be formed to coordinate the volunteer examiner program.

The deadline for comment on the volunteer examiner program falls on April 8, and those wishing to submit comments on the no-code license must do so by April 29.—Avery L. Jenkins WB8JLG.

FCC NEWS

The FCC has paved the way for increased use of experimental digital codes on VHF and relaxed restrictions on ASCII and Baudot transmissions.

In the recent decision, the Commission authorized ASCII up to 56 kilobaud with a bandwidth to 100 kHz on all frequencies above 220 MHz. Between 50 and 220 MHz, the maximum speed is 19.6 kilobaud, and there is no bandwidth restriction.

In addition, experimental codes with a bandwidth of up to 20 kHz are now permitted on the frequencies between 50 and 220 MHz. Previous to this decision, the only permissible codes were ASCII and Baudot. Although the FCC originally wanted to limit the use of experimental codes to domestic transmissions, the final ruling permits their use across the borders of consenting countries such as Canada.

The decision also permits amateurs to use the method of their choosing in determining whether their transmissions fall within the bandwidth limits, and the new regulations do not require continuous monitoring.

Other amendments to Part 97 allow Baudot transmission speed to vary more than 5 words per minute from the standard speeds. The Commission cited the common use of microcomputers rather than electromechanical equipment as the basis of this decision. Frequencies previously limited to F1 have also been opened up to A1 ASCII-coded signals.

The final decision contains several changes from the original proposal. The FCC previously wanted to give its Engineers-in-Charge the power to require amateurs using experimental codes to maintain a record of their communications. However, several public comments noted that the vast amount of material which may be sent by digital methods could be "prohibitively costly to file" and the FFC agreed.

However, hams will still be expected to keep on hand a description of the code which they are using if it is other than ASCII or Baudot.

The Commission also noted that its ability to enforce these new regulations will be hampered by the regulations themselves. "Our ability to verify that the content of messages complies with our rule requirements will be hindered by the broad relaxation of regulatory constraints that we are ordering in these proceedings." However, the FCC added that the "special provisions we are including in the final rules, as well as existing provisions that identification be made in plain English or the international Morse code, should ...provide adequate protection."—Avery L. Jenkins WB8JLG.

Japan in technology. Sure, we're outproducing them in lawyers by about the same numbers as they are outdoing us in engineers and technicians. Perhaps we're going to sue for technology.

CRAPPY AMERICAN PRODUCTS?

I received a letter from a major ham dealer in New Zealand in response to my editorial suggesting that there is need for more engineers and technicians if we are ever going to regain our amateur radio equipment (and other consumer electronic equipment) sales. Of course I didn't suggest this is the *only* problem slowing the sales of American equipment. No, there are several factors which need fixing, such as a tax situation which will allow American firms to spend more on R&D and on growth (which means more jobs).

The letter from New Zealand makes some very pertinent points. There are some exceptions, but in general the quality of products from Japan puts American products to shame. Compare the American equipment side by side with the Japa-

Continued on page 126

QSL OF THE MONTH

This month's QSL contest winner is Dave Shiplett WL7ACY in the frozen north country of Alaska. His card depicts a grizzled 49er panning for gold while listening to an HT propped against a nearby rock. The scene may not be exactly typical of modern Alaskan life, but it quickly identifies the location of David's station. The callsign is made from birch logs, which is a common wood in the Fairbanks area, and the card is drawn by a local artist.

If you would like to enter *73*'s QSL of the Month Contest, put your card in an envelope with your choice of books from *73*'s Radio Bookshop and mail it to *73*, Pine Street, Peterborough NH 03458, Attn: QSL of the Month. Entries not sent in an envelope or without a book choice will not be considered.

Pedal Power: A Perfect Field-Day Generator

This bicycle-driven power source is easy to build and guaranteed to get you in shape. No heavy breathing into the mike, please.

Five QSOs by "natural power." That's all you need for 100 Field-Day bonus points. Did you or your club lose out on those "give-away" points last year? Probably figured it was way beyond your means, right? I mean, how many clubs can sport solar panels, wind generators, Pelton water wheels, or some other exotic power scheme?

Well, phooey. You missed a real giveaway if you skimmed that lightly over this one. You can easily scrounge enough stuff for a real fun-powered machine, even run a contest-within-a-contest if you wish. Let's take a closer look.

Rules

Field-Day rules state that the 100 natural-power bonus points can be earned by completing a minimum of five QSOs without using power from commercial mains or petroleum derivatives. This intuitively means alternate energy sources such as solar, wind, methane, grain alcohol, etc.

How about muscles? Don't they qualify? Especially grain-alcohol-powered muscles. There are usually plenty of 'em around a typical Field-Day site, most standing around getting flabby while their owners fuel themselves with some of those non-petroleum derivatives. Think you're *too* flabby? Heck, it's only five QSOs, and surely there's enough activity on 2 meters or 220 in your area for that. Besides, with a little imagination you can set up a simple contest within your group for the highest number of muscle-powered QSOs (with a suitable handicap for those more heavily fueled).

Muscle Power

In your club or group someone undoubtedly has a small, mobile VHF rig or converted CB. (Single-sideband QRP rigs are ideal, since power demands come in bursts and average power is quite low.) In our club, there are about 40 Midland 13-509s available thanks to a group buy a couple of years ago. On low power (one Watt output), this 220-MHz

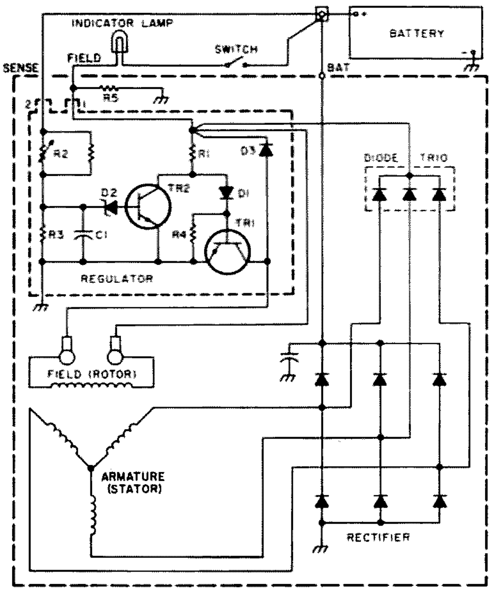

Fig. 1. Alternator schematic diagram.

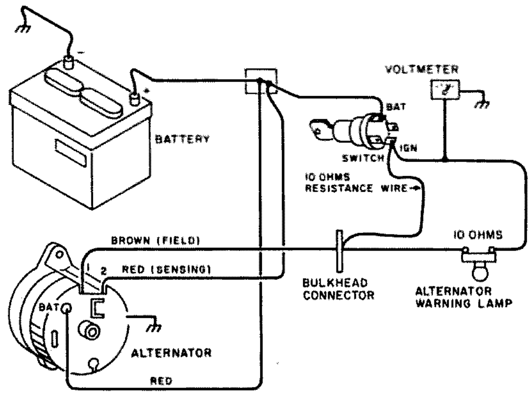

Fig. 2. Typical automobile charging circuit.

rig requires only 1.1 Amps at 13.8 V dc, panel lamps and all. That's 15.2 Watts, or about 0.02 horsepower. On high power (ten Watts), the current zooms to 3.1 Amps, about 0.06 horsepower. Unfortunately, FM means a continuous carrier, but gad, even the flabbiest beer stomach can produce 0.02 horsepower in just one hefty belch! For five QSOs, however, it may take a bit more. Besides, you ought to be listening more than you're transmitting. So how do we turn beer-power into five QSOs? All it takes is a little imagination and some scrounging.

Design

At lunch one day a bunch of club members began to kick around a few ideas, and soon the ingredients for a beer-powered machine began to evolve. An old Delco-Remy alternator was volunteered from one junk box, a little-used exercise bike came from another, and a spare V-belt materialized from the trunk of a car right there in the parking lot. Even a loaner 13-509 was arm-twisted away from its owner in the enthusiasm of the moment.

The pieces began to fall into place. It was decided that it should be rigged so the guy pedaling also had to make the QSOs, all by himself. That way we could run a contest for the greatest number of self-powered contacts. But more about that later. Let's get on with building this contraption.

The Bike

The bike selected should have some means of solidly driving a V-belt. The key word here is "solidly." You'll want to cut all the power losses you can between legs and rig, so no slippage. A multi-speed bike with the rear rim used as a pulley would be ideal, since the gear ratio can be adjusted for the load. The hardest part will be improvising a stand to hold the rear wheel clear of the ground while providing a solid and stationary support for a pedaling rider.

An exercise cycle neatly solves the stationary stand problem, but usually does not provide a gearing adjustment for comfortable pedaling. Nonetheless, since it was free, we opted for the exercycle. The pedaling speed needed to be largely constant to hold the alternator at a constant rpm and could therefore be adjusted by selecting a proper drive-sprocket diameter. A local bike shop proved very happy to help—at no cost—when they understood what we were doing.

If you plan to use an exercise bike, the first step is to disable the friction, weight, or loading mechanism used to increase pedal load. It's going to be hard enough keeping the alternator going. The next step is to decide how best to drive the V-belt. The easiest method is probably to remove the tire and use the rim as a drive pulley. Belt slippage should be no problem even without side contact if the belt is kept reasonably taut. The area of bottom surface contact is large enough to provide sufficient friction.

In our case, however, the semi-pneumatic tire of the exercise bike proved impossible to remove without destroying it. The belt could be driven by grooving the tire, but again that meant destruction. The solution was found in another scrounging trip to the bike shop junk box. A 12" spokeless rim from a kid's bike was unearthed, a rim slightly smaller than the 15" wheel on the exercycle. All that had to be devised was a method of clamping it to the side of the exercise bike wheel. This was done by carefully centering the 12" rim on the 15" wheel and marking points where holes should be drilled for screws, washers, and nuts to be installed as

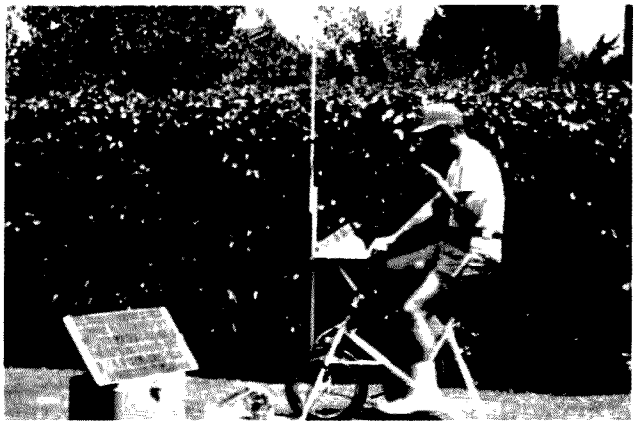

Photo A. The author piling up natural-power QSOs. Note the fuel supply located beneath the solar panel.

clamps to the 15" spokes. Ten such points were marked and drilled and the rim mounted with #8 screws, flat washers, and nuts.

Exact centering of this side-mounted rim is not too important since the speed will be low (about 400 rpm) and some wobble can be tolerated. Be sure, however, that (a) there is clearance for the add-on rim inside the fork, and (b) the V-belt can subsequently be brought forward clear of the tire. Locate the clamping screws alongside the spokes such that the pull on the belt will tend to pull the screws into the spokes, not away from them, or the whole works may slip off the first time the belt is loaded.

Old-timers may recall the popular "Whizzer" bicycle motor of the late 40s and early 50s. The Whizzer motor was mounted on the frame and drove the rear wheel through a V-belt pulley clamped to the spokes. Award yourself a "Scrounge First Class" medal if you can locate one of these old Whizzer pulleys. The enormous V-belt from the Whizzer would be great, too.

The Alternator

Deciphering the innards of an alternator takes just a bit of head-scratching. Our scrounged Delco-Remy was a type with an internal voltage regulator. A schematic diagram and circuit description located in a GM truck maintenance manual proved to be a valuable reference for devising external circuitry for this alternator. The discussion below should apply to whatever type you can scrounge. If you must buy, look for a rebuilt alternator with internal regulator frequently on sale at automobile parts houses in the \$20–\$25 price range.

Our Delco-Remy produced 3-phase ac in the stator that is rectified by six diodes to produce clean, low-ripple, no-whine dc. Regulation is accomplished by sensing the output dc and adjusting the field (rotor) current to hold the output constant over a wide range of speeds and loads. By fixing the high-current stator and spinning the low-current field winding, brushes and slip rings can be kept small, lasting almost indefinitely. Fig. 1 shows the internal alternator schematic, and Fig. 2 its normal hookup in an automobile.

There are three external terminals, a post labeled "BAT," the positive high-current stator output, and two push-on spade lugs labeled "1" and "2", the field and regulator sense inputs, respectively. All US-made alternators are designed for clockwise rotation, looking in at the pulley end of the shaft.

After studying the automobile hookup of Fig. 2, a

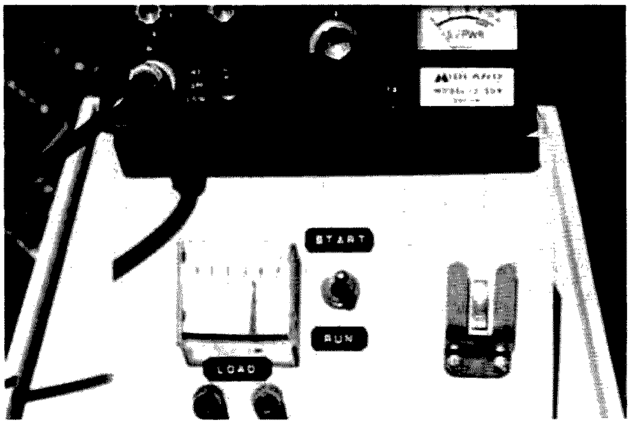

Photo B. The operator's control panel. The transceiver is running directly off the solar panel (see text).

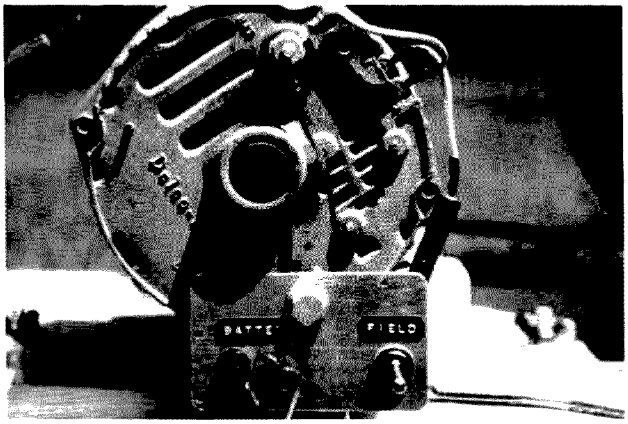

Photo C. The alternator control panel. The field-current source is connected to the BATTERY terminals. The FIELD switch opens the field circuit (see text).

circuit was devised for the bike-powered version as shown in Fig. 3. Start-up field current proved to be the biggest problem, since this is normally supplied from the automobile battery. A close examination of Fig. 1, however, indicates that three internal diodes (labeled "Diode Trio") provided field current when running. These will only work, however, once the alternator stator is producing an output. From a dead stop, no field current is available, so a source of 12 volts must be temporarily connected to terminal 1, then removed after the alternator is up to speed. A switch was therefore included with a START position to initially connect the 12-volt source to the field and a RUN position to open the field line once up to speed. (The extra load on the legs was very noticeable if left in the START position.) To limit field current during start, a 10-Ohm, 10-Watt resistor was included in the place of the automobile alternator warning lamp normally used for the purpose.

The necessity for this external 12-volt source of field current took us back to a careful reading of the Field-Day rules. If we used a battery here, even if only momentarily, would we no longer be natural power? And what if the battery was connected permanently? Happily, the problem disappeared when a small solar panel built of scrap spacecraft solar cells was scrounged from another trip to the junk box. This panel provided more than ample field current, and in fact worked so well that an alternate circuit was improvised to allow running the 13-509 directly off the panel without the alternator. For this mode, another series switch labeled FIELD was added to open the field circuit with the START switch closed, so the alternator field winding would not load down the solar panel. See Fig. 3 and Photo C. (Incidentally, the 15" by 30" solar panel proved adequate to run a 13-509 on high power most of the day, continuing on low power through dusk.)

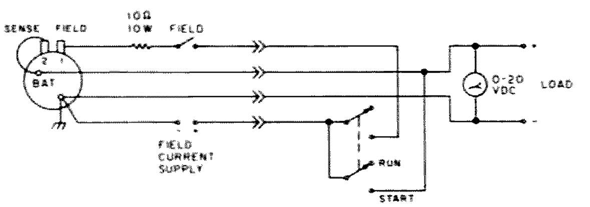

Fig. 3. Schematic/pictorial diagram (the 4-pin connector provides for disassembly).

Mechanical Design

Once the electrical design had been completed, attention turned toward mounting and assembly. A small 10" by 12" tray was fabricated and secured between the handlebars, as shown in Photos A and B. A 7" by 8" stand, angled upward at 40°, was placed on the tray to provide a more convenient viewing angle for the 13-509 front panel and a surface to mount the START-RUN switch, a 0-20-V-dc voltmeter, and the microphone bracket (see Photo B).

The alternator was bolted to a 14" by 20" piece of ¾" plywood which, in turn, was attached with U-bolts to the front foot of the exercise bike (Photo A). By leaving some slack in the U-bolts, the weight of the alternator provided sufficient tension on the V-belt to maintain positive drive, even with some wobble in the bike drive pulley.

Final Adjustments

A final tweaking was required, as mentioned earlier, in pedal speed. The original 7" exercycle pedal sprocket required an uncomfortably high pedal speed for satisfactory operation. Simple proportions between sprocket and pulley diameters can be used to determine the relation between pedal rpm and alternator rpm. (You can also count sprocket teeth and ratio them, if you wish, but diameters are easier.)

Example: Pedal sprocket diameter = 7"; wheel sprocket diameter = 2¾"; wheel pulley diameter = 12"; alternator pulley diameter = 2".

For an alternator speed of 2500 rpm, the wheel pulley speed would be 2500 × (2"/12") = 417 rpm. Since the wheel sprocket and wheel pulley must rotate at the same speed (they are on the same hub), the pedal sprocket speed would be 417 × (2¾"/7") = 164 rpm, about 3 revolutions per second.

Three rps proved to be uncomfortably fast and riders were hard pressed to keep it up very long even with no load. The bike shop once again supplied the answer from its junk box. An enormous 10½" pedal sprocket, installed in place of the original 7" one, brought the pedal speed down to a very comfortable 109 rpm, or less than 2 revolutions per second. This proved so comfortable, in fact, that there was virtually no noticeable increase in load on the legs when the 13-509 was switched on at low power and a barely perceptible leg load on high power. One flabby beer-drinker, microphone in one hand and 807 in the other, completed the required five QSOs before half finishing his 807!

Antenna

The antenna can be almost anything suitable for your Field-Day location. Since we were at a 1500-foot elevation overlooking the Los Angeles basin, a simple home-brew quarter-wave spike with ground plane proved more than adequate to reach all corners of the basin, full quieting. Number 12 solid copper house wire was used for the spike and radials on an upside-down SO-239 connector, as shown in Photo D. A simple angle-bracket and wood pole completed the installation as shown in Photos A and D. For the 220-MHz band, the lengths chosen were about 13" for all elements. At 144 MHz, try 19½", or consult the *Handbook* for something more exotic.

Fuel

Adequate fuel for any Field-Day endeavor must be provided, and Photo A shows the solar panel mounted on an ice chest containing the necessary supply.

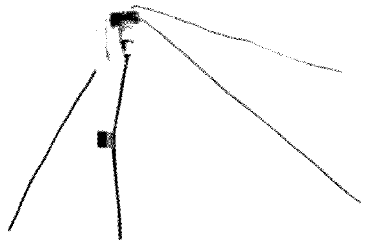

Photo D. The home-brew ground-plane antenna. Radials are #12 house wire.

For a fun competition, set up something such as the greatest number of QSOs per rider before exhaustion. Each 807 consumed might also be counted as a QSO if the flabbier pedalers are to be competing with the athletes. Warning: On VHF, the first few riders will grab off the easiest simplex contacts, so serious competitors should be allowed first crack at these. If you're on ten meters with a converted CB, how about an award for the longest-distance DX, most states per rider, or some such.

As an exercise in computing how much leg power is involved in a horsepower, consider this. The 13-509 on high power transmit consumes 13.8 V × 3.1 Amps = 43 Watts, about 0.06 horsepower. This is about the point where leg pressure becomes noticeable. At 5 Amps (about 0.1 horsepower), it's very noticeable, and at 10 Amps, it's almost impossible to maintain for an average middle-aged ham for even a minute. The pilot (and engine) who pedaled the Gossamer Albatross across the English Channel, Mr. Bryan Allen, developed 0.9 hp for over two hours, an equivalent of 49 Amps! That'll give you something to chat about during your five bike-powered QSOs. (I hope Bryan doesn't show up for our contest. Is he a ham?)

Good luck, and may your club have as much fun as we did with this rig. Who knows, we may score a first with a two-way 807-fueled bike-to-bike contact! Or with good 10-meter openings, perhaps bike-powered WAC or WAS! ■

No-Crash Autopatch

Dialing and driving don't mix. Build this autodialer and let its fingers do the walking—not yours.

Have you ever wanted to make an autopatch call through your local repeater and were afraid to take your hands off the wheel or your eyes from the road and didn't want to stop? Well, I have. And after one particularly foolish and scary experience, I decided to do something about it.

In analyzing my needs, I realized that the only number that I would call via autopatch would be my home phone number. This greatly simplified my thinking. The circuit had to be automatic, easily activated, and small enough to fit inside my rig. My usual mobile station is a Heath 2036A with touchtone™ capabilities that works fine. I have used it several times to call home very successfully. But with my family of drivers, sometimes my mobile station is visiting the hairdresser or the shopping mall and I am left with the cantankerous clunker. I know I should remove the rig whenever I leave the car, but that grows tiresome. When I must use the clunker, I take along my "kitchen rig," a single-channel, homebrewed, plain-vanilla, no-frills thing. In these days of fully-synthesized, scanning, computerized transceivers, my kitchen rig is nothing to brag about. But it was my first experience on FM, and it was built to see if two-meter FM was my bag before investing lots of bucks in a better rig. I probably will always have it so I decided to add the automatically-dialed autopatch feature inside.

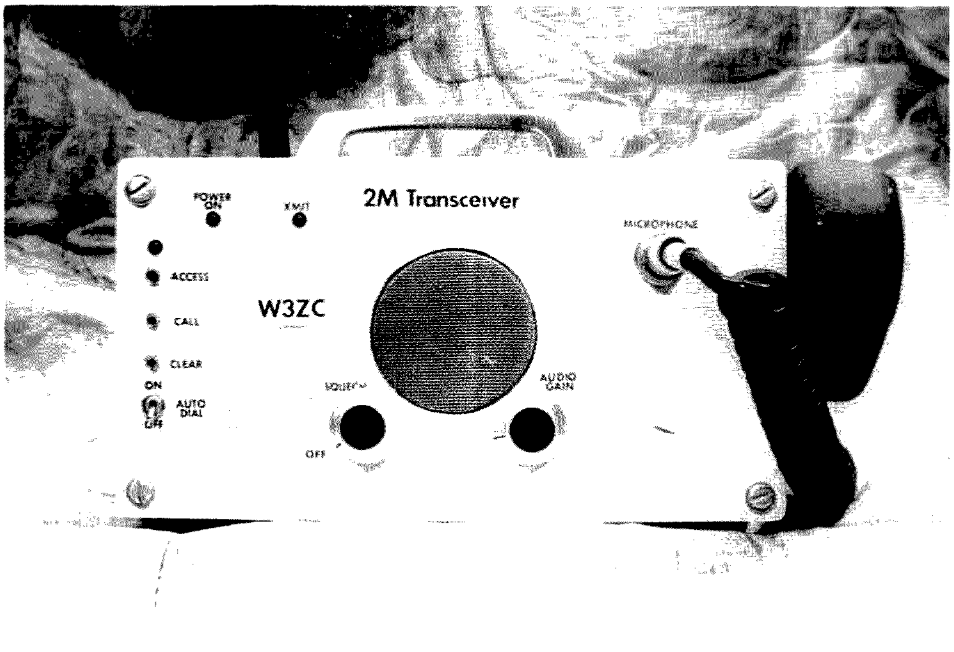

Photo A. Front-panel mounting of switches and LED.

The kitchen rig is not what you would call miniature, but there isn't an awful lot of room inside. Ten C-sized nicad batteries take up a lot of space. Therefore, the addition of autopatch had to be small enough to fit into a corner and had to be easily operated. The circuit of Fig. 1 evolved.

Circuit Description

The heart of the circuit is the 8223, U5, a 32 × 8 programmable read only memory, or PROM. This IC, in effect, replaces the touchtone pad used in normal autopatch applications. The memory inside the PROM must be programmed before being used in any circuit. This circuit is no exception. A detailed description of the PROM programming that I used in the dialer will be discussed later in the article.

Basically, the PROM is separated into three memory segments. One is used for access, one for the phone number, and one for clearing. If programmed and addressed properly, the PROM sequentially drives the 14410 encoder chip, U6, to automatically produce the tones for accessing the patch, dialing the number, and clearing the patch. The PROM is addressed by U4, a 74393 dual four-bit binary

counter. The counters are cascaded because five binary bits are required to address all 32 words in the PROM. A sixth bit drives the end-of-message gate and the remaining two bits are unused. U3 is configured as a free running clock and controls the system timing by stepping the counter through the clock gate, U2A. A pot is used to set the timing.

U1A and U1B are connected as a set-reset flip-flop. This flop is used as the start/stop element by opening or closing the clock gate, U2A. Power-on reset is achieved via the RC network connected to pin 5 of U1B. The flip-flop is set by the ACCESS push-button which starts the operation and is reset by the CLEAR push-button or by the end-of-message gate, U2B. U2B becomes active at count 32 of the counter. I have found that this memory size is more than adequate for the dialer. If you decide to shorten the dialing cycle to less than 32 words, you can use the two inputs tied to Vcc on U2B to perform the logic. The reset, or abort circuitry, consists of gates U1D, U2C, the three germanium diodes, and the CLEAR push-button. Germanium diodes are used because of their low forward voltage drop.

A three-terminal regulator provides the five volts required for IC operation from the 12-volt line in the transceiver. Liberal use of bypass capacitors on the five-volt line is an absolute must. Digital logic and rf are like oil and water—they don't mix too well.

Because my rig is battery powered, I have included a separate switch to remove power when it is not in use. Also, Q1 is used in the Vcc line of the PROM to save about 20 mA of battery current when the circuit is in standby. External connections are made to the transceiver 12-volt line, ground, and the microphone input line. An output pot adjusts the signal level to the transceiver mike amplifier stage.

The PROM

A PROM has the ability to internally store information in the form of ones and zeros as defined by the user. The 8223, U5, is organized as 32 words by eight bits per word. This simply means that there are 32 combinations of the eight outputs. A PROM differs from a random access memory, or RAM, in that a user can write differing combinations of ones and zeros into a RAM and can change them at will. Of course, this means that you will need additional circuitry to perform the write cycle. If the desired program is fixed and will not change, then a PROM is a better choice. You will not need the additional circuitry, but you had better make sure your program is right the first time or you have lost a PROM. You can change PROMs but you can't change what's inside. You must decide at the onset what program will be "fused," or "burned."

A problem that the builder may encounter is how to go about getting his PROM

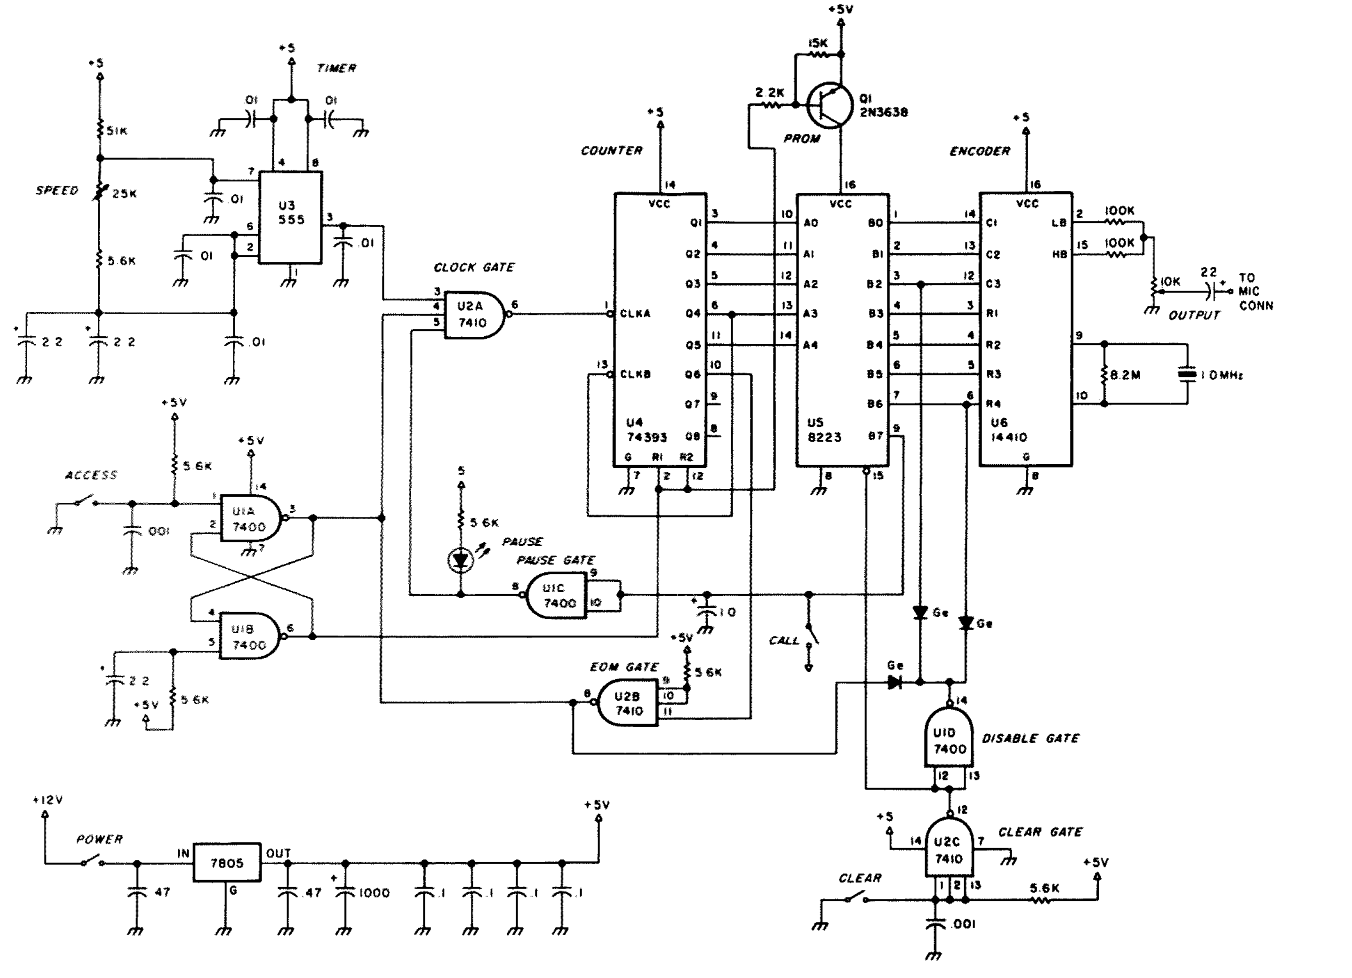

Fig. 1. Schematic of automatic dialer. All resistors ¼ W. All capacitors in µF. All pots screwdriver adjustable.

burned. Since I am employed in electronics, I never had this problem. There was always a PROM burner available. But all too often a writer makes the wrong assumption that everything is available to everyone. However, all is not lost. There are many hams who work in electronics and perhaps one of these fellows could help you out. Ask around. It doesn't take very long to burn a PROM with modern industrial equipment, so your obligation won't be that far-reaching. If all else fails, then you can always take the rough road and breadboard yourself a programmer. I refer you to the article by WB2CZL entitled "An 82S23 PROM Programmer" (*73 Magazine*, June, 1977).

Once a programming source has been located, you must decide what to program. The PROM output lines feed a standard encoder chip, U6. The 14410 requires only seven inputs, so that leaves one PROM line

Desired Tone	PROM Outputs Required to be Low
1	B0 and B3
2	B1 and B3
3	B2 and B3
4	B0 and B4
5	B1 and B4
6	B2 and B4
7	B0 and B5
8	B1 and B5
9	B2 and B5
*	B0 and B6
0	B1 and B6
#	B2 and B6

Fig. 2. PROM programming necessary to produce the desired tones. Create a chart as I did in Fig. 3. Word 00 must be as I have defined it. Select the tones you want and refer to the above figure to determine where the zeros must go. Everything else is ones except for B7. Insert a one at B7 where you want a pause. Start at word 01 and fill in the ones and zeros. The tones will be sent in the sequence that you have defined them on the chart.

free. This line is used as a control bit to perform the pause function between access and call, and call and disable. Refer to Fig. 2 for the programming required to produce the desired tones. I recommend that you write out the entire program map as I have done in Fig. 3. PROMs of this type come supplied with zeros in every location and you need only be concerned about which bits of which word should be burned to ones. However, seeing the entire bit pattern will make it easier to ensure that your bit pattern is burned correctly the first time.

Notice in Fig. 3 that B7 is at a high twice in the sequence. This causes two pauses in the dialing program. Thus, the program is divided into three segments. The first segment is used to access the patch. Our local repeater requires three tones for access and, in my program, six words of memory. Word 00 causes no tones to be produced and is used as the rest state. Inactive states are also placed between the desired tones to separate similar consecutive dial tones. If your access code on your repeater requires two tones instead of three, program words 01 and 02 for the first tone and 04 and 05 for the second. Circuit capacitance and speed are such that each tone spread over two words will sound as one continuous tone at the output. Should a single tone access be required, program words 01 through 05 for that tone. On the air it will come through uninterrupted. Word 06 contains a high on B7. This stops the sequence and causes the LED to light. A lighted LED indicates that the access tones have been sent.

The second segment of the program contains the information necessary to produce the tones for the telephone number. Notice again the inactive words between the desired tones. Should your phone number require a 1 in front of the seven digits, you will need a larger second segment. Instead of programming B7 for a one at word 21, leave it at zero. Make B7 a one at word 23 and you will have enough room to incorporate the eight digits. A pause should always be followed by an inactive state to allow things to settle before the program continues.

The third segment of the program is used to disable the patch. In my case it required a single tone. As many as three tones can be inserted in the disabling segment. Do not plan to use any words beyond word 31 because you will be out of memory and the sequence will loop back to the beginning until a high at B7 is encountered. As stated earlier, you can use the entire 32 words of memory.

A comment about word numbering: Word 00 counts as a word in memory-logic descriptions. Therefore, word 31 is in reality the 32nd word in the sequence. The same is true of bit numbering. Bit 0, or B0, is the first bit in the output scheme. B7 therefore is the eighth bit. Don't blame me. It's what is known as convention.

The circuit consisting of U1D, U2C, the CLEAR pushbutton, and the three germanium diodes is designed for a single-tone disable. If your repeater requires more than one tone to disable the patch, this circuit is of no

PROM Address	PROM Output Lines B0	B1	B2	B3	B4	B5	B6	B7	Tone Sent

*Fig. 3. PROM programming used at W3ZC to access patch, dial number, and disable the patch. Access code is * 5 6, my home phone number is 8 2 2 8 8 4 8, and a # series is used to disable. A high at B7 produces a pause at the end of the access tones and at the end of the phone number. The CALL or CLEAR push-buttons override the pause.*

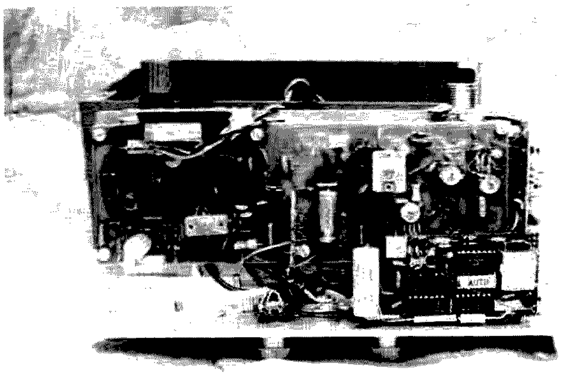

Photo B. The position of the automatic-dialer board inside the transceiver. The board is at the lower right.

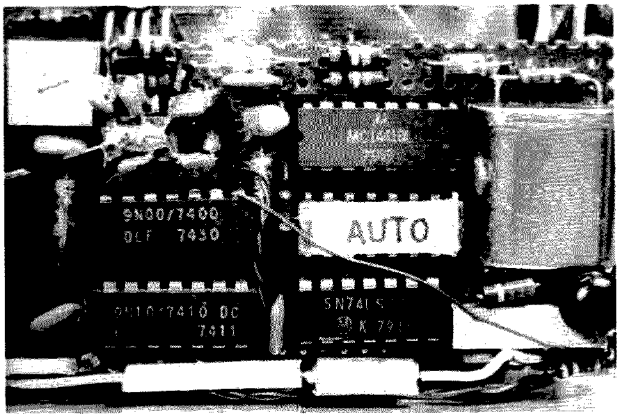

Photo C. ICs are mounted in sockets and pots are PC type. The crystal is at the right and Q1 is mounted between the crystal and the output pot. The speed pot is at the upper left. The 555 assembly is next to the speed pot and is described in the text. The PROM is under the AUTO stick-on label.

use to you. Eliminate it and ground pin 15 of U5 directly. The program must then be used to perform the disabling function. This CLEAR circuitry was incorporated to abort everything should a malfunction occur anywhere in the entire sequence.

Construction

The six ICs and associated components are mounted on a 1½″×2½″ piece of perforated circuit board. Point-to-point wiring is used throughout. Shielded cable should be used at the output. Keep in mind that there may be a lot of rf floating around inside the cabinet, a situation that I encountered during checkout. I instinctively tried a shield over the top of the board. It didn't cure the problem, but it looked like a good idea to retain it. You might want to try yours without it at first.

Notice in the photo the unusual arrangement around the 555 timer. Rf made this chip go wild. The solution was to strip some copper foil from a piece of printed circuit board material, cut it to the size of the 555, place it on top of the chip, and wire it to pin 1 of the chip itself. Bypass every pin on the 555 with a .01-uF capacitor. Don't leave your iron on the IC pins too long. You don't want to ruin the chip. I used sockets for my ICs and if you do, you'll have to wait until you are ready to insert the ICs before shielding the 555. Don't try it on the bench. Solder may run down the leads and you'll never get the chip into the socket. Your installation may not require these extremes, but if your timer is also affected by rf, the solution presented here should work.

An appropriate spot must be found to mount the 7805 three-terminal five-volt regulator. A single hole is required somewhere on the chassis. I used heat-sink compound on the regulator but, in retrospect, it's probably not required. The circuit draws a little over 60 mA and the 7805 should take it without the compound. Just make sure that the mounting surface is flat.

I mounted the three form A push-buttons, the LED, and the toggle switch on the front panel. Bypass the switch contacts right at the switch.

The whole circuit could be built into an external box if you don't mind carrying around another piece. Interconnections would be Vcc, ground, and a shielded audio cable. This arrangement also might alleviate the rf pickup problems.

Operation

The operation of the automatic dialer is described in the following steps:

1. Turn on the toggle switch to power the unit.
2. Depress the mike button and announce your intentions.
3. Still holding the mike button down, push the ACCESS push-button. This produces the tones required to raise the patch.
4. When the LED comes on, release the mike button to determine if you were successful in accessing the patch. If you were, you should hear the dial tone. If you don't hear a dial tone, push the mike button and abort the procedure by depressing the CLEAR push-button and try again.
5. When you hear the dial tone, push the mike button and depress the CALL push-button. When the number has been automatically dialed, the LED will come on again. Release the mike push-button.
6. If you hear nothing but empty air, or if Ma Bell blisters you with one of the taped messages, abort and give it another try. If the ringing is heard, then abide by the customs and procedures appropriate with your repeater. On mine, you announce your callsign and the telephone exchange.
7. When the phone is answered, indicate that the conversation is going out on the air. Complete the call.
8. To knock the patch down, depress the mike button and the CALL or the CLEAR push-button.
9. Turn the toggle switch off.

The CLEAR push-button can be used at any time in the procedure to cancel the whole cycle.

Adjustment

Adjustment of the circuit is easiest if an oscilloscope is available. Double check your wiring before turning on the power. Remember that ICs are totally unforgiving if you have made a mistake.

Turn on the power-on toggle switch and depress the CLEAR push-button. Check pin 3 of U3 for oscillation. Do not turn on the transmitter at this time. You should see pulses of several hundred milliseconds in duration. You should be able to see a speed change when varying the speed pot. Usually in the whole autopatch cycle, the limiting factor as far as speed is concerned is the response time required by the repeater to access. The telephone lines will accept tone durations as short as 70 milliseconds. Rarely will you find a repeater that will respond to

autopatch access commands in a period that short. You'd best start out at a period no faster than 300 milliseconds.

Move your scope probe to pin 6 of U2 and depress the ACCESS push-button. You should see the clock pulses as they pass through the clock gate. Keep your probe on pin 6, U2. At the end of the access count, the pulses should stop and the LED should come on. Reset the circuit and trace the pulses (after restarting) through the counter and the PROM. Check the top of the output pot with the scope. When the circuit is running, you should see two superimposed sine waves representing the required tones for a dialed digit.

If you don't have a scope, you can use your 20,000-Ohms-per-volt voltmeter. Read the voltage at the output of the 555. The reading should be greater than zero and less than five volts. Move the positive lead of your voltmeter to pin 6 of U2 and press the ACCESS push-button. You should read essentially the same voltage as you did at the clock output until the LED comes on. At that time the reading should be zero. Put your voltmeter on ac and move it to the top of the output pot. Push the CALL push-button and you should notice a reading on your meter. This is a high impedance point so the reading will most likely be small. If you don't get a reading, move your voltmeter to pin 2 of U6 and try again. This point is lower impedance. If you still don't get a reading, you will have to trace the pulses through the counter and PROM. Pin 3 of U4 will change states with every pulse, so you should notice something there. As far as the PROM is concerned, pick the output from your PROM map that changes most frequently and look at that particular pin. Checkout of the gates should be straightforward. A high should be read at the output of U1C when tones are being produced, and a low when the sequence is completed. At the output of U2B you should see a high after you depress the ACCESS push-button. It should go low at the end of the entire cycle or when the CLEAR push-button is pressed. By this time, you should be fairly confident that the circuit operates, and you are ready for an on-the-air test.

Enlist the aid of another ham and, if you can, go to a simplex frequency or to a repeater without a patch. Run through your sequence and adjust the output pot as required to produce clear tones. Make sure your companion is as objective as possible. Once the output is adjusted properly, you can give it the acid test on the repeater. If you can't go to a simplex frequency, you'll have to do your testing on the autopatch repeater. Pick a time when it is not busy and give it a try. You may have to adjust the timing to be compatible with the repeater access response. The repeater control op should be able to help you if the tone timing needs lengthening.

Conclusion

If you follow the circuit diagram carefully and play by the rules, your automatic dialer will be a useful addition to your amateur gear. I am also sure that there is room for improvement. Ask yourself what you really want out of the unit and sit down with an IC spec book, pencil, and paper. You will find that your understanding of digital circuitry will improve, and the mistakes and successes of your changes will help you to debug other circuits that you may encounter in the future. ■

80M IN 24 FT!

Put a broad bandwidth 80M dipole in 24 ft with the SLINKY DIPOLE® antenna. Comparable low SWR, space savings and performance on ALL HF bands, including SWL and WARC. Complete kit: 2 special 4" coils, 50' RG-58/U coax, balun kit, mounting hardware and instructions. Great for apartments, condominiums, motels and vacation use. Easy set up and adjustment.

Turn Mobile-Rig Whine into a Whimper

From brute-force filtering to solid-state regulation, K4AJQ has the answers to mobile noise.

If you've spent some time monitoring your local repeater, you should have noticed that some of the signals being relayed could stand some cleaning up. Many of these signals have hum or noise mixed with the audio. Often these are due to a malfunction in the transmitter or transceiver. Many times, however, the source can be traced to the power supply for the rig. Audio hum is fairly common for base stations. It often is caused by a lack of sufficient filter capacitance in the ac power supply or a defective regulator. The noise is usually not a hum in mobile rigs, but it has almost identical causes.

The noise present on mobile signals usually sounds like a whine and can easily be traced to the car's alternator. I have found that alternator whine is a commonly-encountered problem, and it is sometimes very difficult to suppress. Over the years, I have discovered several methods of dealing with this problem. One of them should work for you.

The Problem

The automobile alternator generates alternating current. Because the alternator is driven by the car's engine, the frequency of this alternating current depends upon engine speed. The pitch of alternator whine depends upon the frequency of the ac current. It is this ac that causes problems in most mobile rigs because they are designed to operate from pure direct current.

Before the alternator output can be used to power car systems, it first is converted to dc. This conversion, called rectification, is done by silicon diodes which usually are mounted right in the case of the alternator. The dc then is used to charge the car battery and to power the automotive systems.

Unfortunately, the output of the rectifiers is not pure dc. Because it is composed of rectified sine waves, it still possesses a characteristic frequency which can be related to engine speed. It is this frequency component which must be removed from the power line to the rig to prevent it from being transmitted along with the desired audio signal. The two methods I have used to do this are filtering and regulation.

Filtering

A brute-force method of removing alternator whine is low-pass filtering of the power line. This can be done by using an inductor or an inductor-capacitor combination.

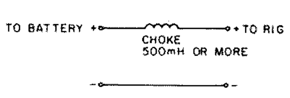

Fig. 1. Inductor used to suppress alternator whine.

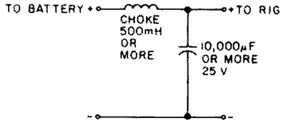

Fig. 2. Inductor-capacitor alternator-whine filter.

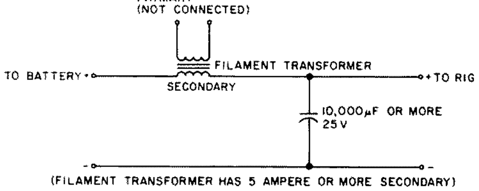

Fig. 3. Alternator-whine filter using filament transformer for inductor.

Fig. 1 shows the simplest whine-filtering circuit. You should use the largest value of inductance available. However, the resistance of the inductor must be low enough so that the voltage drop across it is not excessive. To find the maximum allowable voltage drop, you can connect your rig to a variable-voltage power supply and lower the voltage while transmitting until the power output into a

dummy load starts to fall off noticeably. Next, measure the car's battery voltage with the engine off. From these two measurements, you can calculate the maximum permissible inductor resistance.

With my rig, the power output started to fall off when the voltage was reduced to 12.2 volts. At this voltage, the current drawn was 5.4 Amperes. The car's battery voltage with the engine off was 13.6 volts. Therefore, the maximum permissible inductor resistance was $R=(13.6-12.2)/5.4$, which is 0.26 Ohms.

In Fig. 2, the filter contains both inductance and capacitance. I have found this circuit superior to the one in Fig. 1 and have used it many times. The added filtering provided by the large value of capacitance allows a smaller value of inductance to be used than would be necessary if only an inductor were used to provide the necessary filtering. When this circuit is used and the same inductor is used that was used in the circuit of Fig. 1, the filtering will be better than is possible with the inductor alone.

I have found that filter chokes (inductors) capable of carrying 3 Amperes or more are hard to find in the average ham's junk box. Over the years I've found them only in military surplus gear. A very good substitute is a filament transformer with a secondary winding capable of 5 Amperes or more. I have used 5-volt, 6.3-volt, and 12.6-volt filament transformers. These are plentiful in the junk boxes of us old-timers, who were around before the solid-state invasion. They are available also from many of the surplus dealers who advertise in *73*. Fig. 3 shows a whine filter using a filament transformer.

Regulation

Transistors are here to stay. I finally convinced myself of that and set out to see how those little devils worked. All of the inductor-capacitor whine filters I have built are big and heavy. This was no problem when gasoline was cheap and cars were large, but when I recently purchased an imported subcompact, I found my alternator filter wouldn't fit. In fact, it was almost as big as my engine. *I immediately set out to solve the alternator-whine problem another way—using electronic regulation instead of brute force.*

The circuit shown in Fig. 4 was developed experimentally. It completely removes alternator whine from the transmitted signal. I have tested this regulator circuit in three cars and found the performance the same in each. I have constructed the circuit using point-to-point wiring and using a PC board with the components mounted on the foil side. I used foil on the board for heat-sinking of the two MJE3055 power transistors in the printed circuit version. This has proven more than adequate for use with my mobile rig, which draws 1.5 Amperes on receive and 5.4 Amperes on transmit.

The components used in the regulator are not critical. Almost any NPN power transistors with adequate current-handling capability can be used instead of the MJE3055s.

Transistor Q2 and diodes D1 and D2 form what is known as an amplified zener diode. Essentially, it is a zener diode with the zener voltage the same as that of D1 and a power rating the same as that of Q2. I claim no originality for this circuit. It is old, and I no longer even remember where I first saw it. Fig. 5 further explains the amplified zener concept.

Conclusion

In this article, I have shared with you some ideas for ridding your signal of alternator whine. Some rigs are much more susceptible to whine than others. If your rig is one of those that could stand some cleaning up, get out the old soldering iron and have at it. Either the filtering method or the regulation method may be used. Both give excellent results. ■

NEW ELECTRONIC KITS

ALL IN ONE RTTY DEMODULATOR KIT

FEATURES -- ON BOARD POWER SUPPLY AFSK GENERATOR, PROVISIONS FOR LOOP SUPPLY, ACTIVE FILTERS OR OPTIONAL TORROID FILTER, AUTOSTART, ANTISPACE PCB KIT NO. 23-1770 SB-60 $169.95

RTTY SPEED CONVERTER

CONVERTS 60, 75 & 100 WPM BAUDOT CODE TO 100 WPM CODE FOR BAUDOT MACHINES REVERSES SAME FOR SENDING. FEATURES SELCAL, BUFFERING AND INTERFACE FOR BAUDOT PTR. PCB KIT 23-1814 $89.95

BAUDOT / ASCII CONVERTER

MICRO BASED RTTY CONVERTER CONVERTS BAUDOT TO ASCII FOR RECEIVE, ASCII TO BAUDOT FOR TRANSMITING. FEATURES SELCAL, BUFFERING AND INTERFACE FOR 110 BAUD PTR. PCB KIT 23-1815 $89.95

AUTO CW-ID KIT

FEATURES ON BOARD TEN MINUTE TIMER WITH TTL, PLUS/MINUS 12 INTERFACE AND UP TO 32 DOTS, DASHES OR SPACES. PCB KIT NO 23-1721 4-1/2X6 $29.95

ONE AMP POWER SUPPLY KITS

BELOW 3 KITS 22 EDGE CON 4-1/2X6

Exploit the Hidden Interfaces of the TRS-80

Sound synthesis, a programmable timed on-off switch, and a CW keyer are all hidden in the TRS-80. You just have to look in the right place.

One day a friend was comparing his Apple II with my TRS-80, pointing out all its special features. Color graphics . . . that's nice. What do you mean, the TV is extra? High resolution graphics needs 16K just to hold the display! I guess I can live without color graphics. Built-in speaker . . . WOW! Now that's something I could use. As limited as the TRS-80 graphics are, sound would sure be a plus to some of the games. It would also come in handy to signal editing errors in programs. And how about a metronome accurate to 1/400 of a second? Too bad there isn't a cheap, easy-to-hook-up interface available. Ah-ha, but there is. And it won't cost you a cent; it's already built in. Didn't know that, did you? How do you think you CSAVE and PRINT#-1 data to the cassette recorder?

The only accessory you will need is an audio amplifier and speaker. What? You don't have an amp! I'll bet you do. What about that pocket radio you junked because the only way you could pick up a station was to stand under the transmitter's antenna. Well, the amplifier's still good. All you have to do is open it up and tap into the volume control. Assuming that most volume controls are generally wired the same, refer to Fig. 1 for hookup details. Note the 3 lugs on the volume control. Ignore the center lug. Remove the plug from the AUX jack on the cassette. Connect a wire from one outside lug of the volume control to the tip (inner conductor) of the plug. Connect another wire from the other outside lug to the ground on the plug. You might have to switch leads to get the loudest output.

If you find you may be using this newfound accessory quite often, you may want to rewire the earphone jack on the radio (no one uses it anyway). Then all you have to do is remove the plug from the AUX jack and insert it into the earphone jack on the radio.

If you really want to get fancy, there is plenty of room inside the video monitor for a home-brew amplifier and speaker.

Now to the meat—how to create the sound!

As you know, sound is made up of sine waves. But the closest thing to a sine wave that a computer can generate is a square wave. OK, so how do I make a square wave? The instruction we use is the OUT instruction to port number 255, using bits 0 and 1. Turning bit 0 on (OUT 255,1) creates the positive half of the cycle. Turning bit 1 on and resetting bit 0 (OUT 255,2) creates the negative half of the cycle (see Fig. 2). Generating 1 cycle won't give you much of a beep. That's where the FOR . . . NEXT loop comes in handy. Try the following:

```
1 DEFINT I-N
10 FOR I = 1 to 200
20 OUT 255,1
30 OUT 255,2
40 NEXT
```

Now we're getting somewhere. Changing the length of the loop will change the length of the beep. BASIC, being much slower than Assembler, will limit the range of tones you can generate. This example is the highest note you will be able to obtain using BASIC.

Any type of delay you might have between the positive and negative cycles will result in a lower frequency.

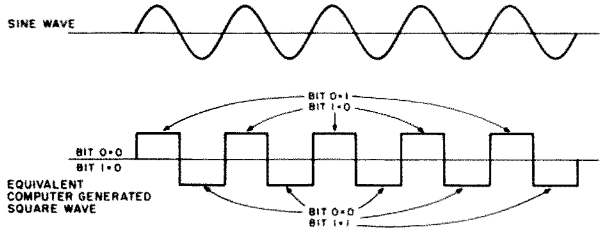

Fig. 2.

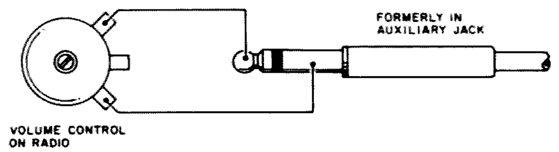

Fig. 1.

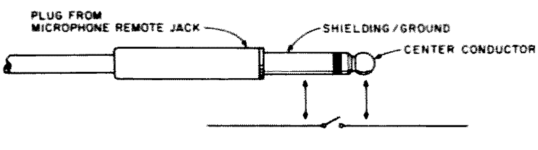

Fig. 3.

Insert the following statements in your program:

25 FOR J=1 TO 5: NEXT
35 FOR J=1 TO 5: NEXT

Experiment with a few examples of your own.

How about a pulsating tone:

```
 1 DEFINT I-N
10 FOR I = 1 TO 30
20 FOR J = 1 TO 10
30 OUT 255,1: OUT 255,2
40 NEXT
50 FOR J=1 TO 10: NEXT
60 NEXT
```

The major loop (lines 10-60) will generate 30 beeps. Lines 20-40 will create each individual beep. Line 50 will create the space between beeps. Line 1 will reserve names starting with I through N for integers. This is a good practice, for it costs only about 10 bytes which you quickly make up by leaving out the "%" to define an integer. Also, your loops will run faster using integer variables. Besides, have you ever tried to keep track of all those %!#$%!#$ variables?

Thought of any other uses for sound yet? If you think you have a good idea, let us in on it.

Now I'll show you another little-known interface which is standard on the Level II.

What use could you find for a programmable on/off switch? Well, just about any type of computerized timer imaginable.

Inside the keyboard there is a small relay used for turning the cassette recorder on and off. Next time you CSAVE or CLOAD, listen for the relay. Remember that this is a small relay designed only to control the cassette. Radio Shack warns of trying to control your air conditioner with it, but if you must, let this relay control another buffer relay which, in turn, could handle the higher power.

How do I make connection between the computer (controller) and the device I wish to turn on and off (controllee)? First disconnect the plug from the remote jack on the cassette. Referring to Fig. 3, identify the two parts of the plug. Consider these two parts as you would the two terminals of an SPST switch. You can use alligator jumper leads for now, but if you're going to be using this feature often, you might want to wire up a jack to the controllee. Then all you would have to do after you CLOAD the program is remove the plug from the remote jack and reinsert it in your newly installed jack.

OK, I got it hooked up. Now what? The instruction we use, to finally make this all work, is the OUT instruction to port 255. What's that, you say? That's the same port we used to make sound? True, but we used bits 0 and 1 to make sound. To control the relay, we use bit 2. To turn on the relay, bit 2 must be set to 1 (OUT 255,4). The relay will remain on until bit 2 is reset to 0 (OUT 255,0) and will remain off until set again.

With the right FOR... NEXT loop(s), you could program a timer to turn *on* or off any device for any amount of time from 1/400 of a second to weeks or months. I won't get into any timer statements here. There are plenty around that you can adapt.

I'm going to let you simmer in this sauce of new knowledge for a while and let you come up with some ideas of your own.

I guess you're wondering what this is all leading up to. What possible use could the ham have for these features?

Well, how about something practical that every ham can use. Have you thought of it yet? Time's up. It's a variable speed, 10-message-memory CW keyer. Told you you'd like it.

Let's go through the program and see just what it will do for you. First of all, we have to come up with some system of encoding our message. We'll use a 59 by 6 array to hold our code table. 59 was chosen to hold all ASCII codes from 32 through 90 (space, special characters, numbers, and the alphabet). 6 was chosen to hold the elements of the larger characters like "." and $\overline{SK}$. A 1 indicates a dot while a 3 indicates a dash. A 2 is used only once for the space code. "0" is used only as a filler or position occupier. Example: "A" will be coded as 1,3,0,0,0,0. Data statements 100-103 define our codes. As you have probably figured out, there are no CW codes for a "#" or a "$". You can still put this space to good use. For example, this program used the "#" as an error, "$" as $\overline{KA}$, "%" as $\overline{BT}$, "&" as $\overline{SN}$, "(" as $\overline{AR}$, and ")" as $\overline{SK}$. Also notice that the comma (3,3,1,1,3,3) is coded twice. The real comma (ASCII 44) will never be used because any comma used in an input string would assume you are asking for two different input variables. To get around this, the semicolon (ASCII 59) is also coded as a comma. You could actually put it in any unused position. A similar problem occurs when using the colon (ASCII 58), so I coded it in the "*" position (shift colon).

At line 500 we set aside enough string space for our message-memory buffers and define our code table.

At line 600 we load up our table from the data statements.

Line 700 gives us the option of using our built-in oscillator (tone) or using our programmable switch (relay). For hookup directions see above. Please keep in mind the small relay. Don't hesitate using a buffer relay.

Program listing.

Line 800 sets the initial speed to 15 wpm. The tone-generating loop takes about 3 times longer than the relay loop, which accounts for the different initial speeds.

Line 1000 asks for the message you want to transmit. At this point you can also enter these key words:

"P" will print the contents of all memory buffers not null or blank.

"MS#", where # is any number from 0 to 9, will permit you to store an often used message (example: CQ CQ CQ DE WB9EGA), up to a length of 256 characters, in the buffer number requested.

"MR#", where # is any number from 0 to 9, will recall a message from the buffer number requested. After a recall, all you have to do to transmit the message is hit ENTER.

"CS" allows you to change the speed of transmission. Increasing the number increases the length of the timing loops, which in turn lowers the wpm.

Lines 1010-1030 take care of the print option.

Lines 2000-2010 control the storing of a message into buffers 0-9.

Lines 3000-3010 recall a message from a buffer.

Lines 4000-4010 display the current speed and ask for the new speed. If you decide not to change the speed, just hit ENTER.

Lines 5000-5500 do the outputting of the message. Here we get a little fancy. We clear the screen and print the entire message. On the next line, we print every character as it is transmitted. This lets you know where you're at. At 5000 we also get the ASCII code of each character and subtract 32 to point us to the right entry in the table. We also check to see if you accidentally entered a lowercase letter (ASCII 97-122). If you did, we convert it back to an uppercase letter so it will fit within the bounds of our table.

At 5100 we scan the 6-digit code of the character we are encoding. If the code is a 1 or a 3, we continue at 5200. If it is a 2, we process a space at 5400. If it is a 0, we do nothing but run out the scan counter.

Line 5200 does the timing for dots and dashes. First we check for relay or tone control:

If relay control—We turn on the relay and delay the right amount of time depending if this is a dot or a dash. A dash being 3 times longer than a dot, you can see why I chose 1 for a dot and 3 for a dash. We can use the same timing loop for each just by using this variable. Anyway, after this time, we turn the relay off and perform another timing loop the length of a dot. This gives us the spacing between the dots and dashes within the character.

If tone control—Basically the same idea as the relay logic except instead of turning on and off a switch, we must generate a square-wave signal.

Line 5400 is a timing loop used for the spacing between words.

At line 5500, the FOR . . . NEXT timing loop is used for the spacing between characters.

And that just about wraps up this exploitation of your TRS-80.

I can't think of any reason why any ham with a TRS-80 would not try this program. Think of the time it would save during contests. This program alone could justify, to your other ham friends, why you bought a TRS-80 instead of that 800-channel, programmable, scanning, remote-controllable, portable, glow-in-the-dark 2-meter rig. Well, here it is. Enjoy.■

We're changing what repeaters can do . . . for YOU!

Whether you're a repeater owner, control op, or user, the RC-850 controller offers you capabilities you've only dreamed of. Like natural sounding speech synthesis . . . easy, remote Touch-Tone programming . . . talking meter readback . . . synthesized remote base operation . . . and an autopatch with features you have to hear to believe.

Most important of all, upgrade through software, prevents obsolescense. Which lets us bring you new features, like our scheduler, for automatic changeover of repeater status by time and day of week . . . And our mailbox, for leaving messages for your friends. Plus much, much more!

The RC-850 Repeater Controller—The New Standard in High Performance!

Ask anyone that owns an RC-850 controller. Or ask us for our demo tape, so you can hear for yourself.

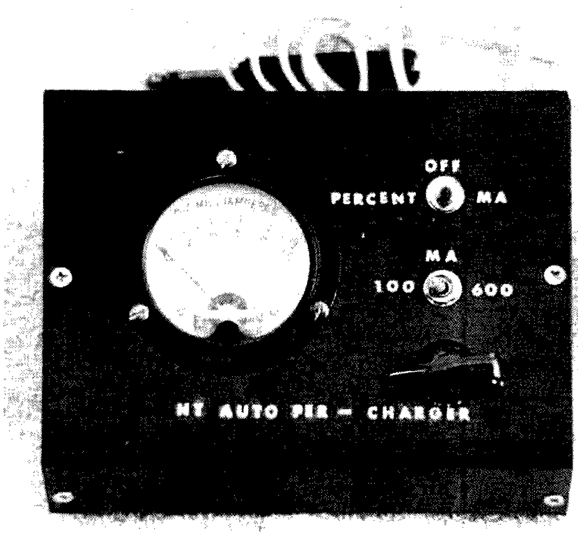
New England's Nicad Per-Charger

Build this and get state-of-charge readout, automatic shutdown, and charge maintenance for your HT. This could be the gift of life for your battery pack.

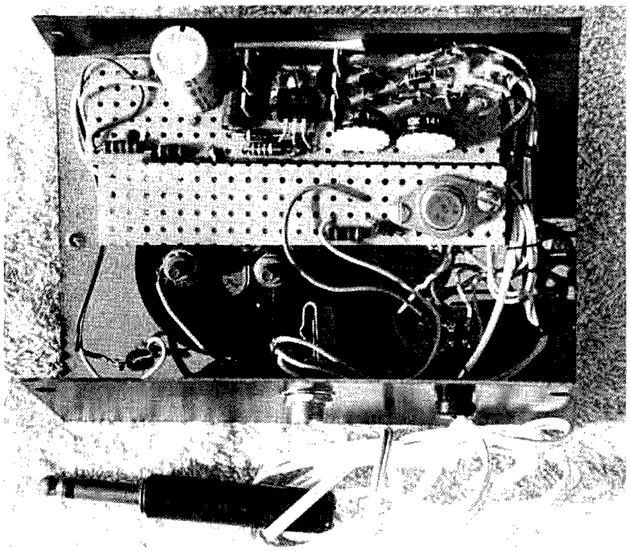
If you use an HT, you will very likely have two battery packs. Proper cycling of charge and discharge is essential for long life for nicad batteries. Carelessness in this regard has recently cost us cells in three nicad packs. One was in a pack for an FT-207; the others were in packs for TR-2400 radios.

Use of the HT auto per-charger will remedy this. It was designed for mobile use, but we have found it invaluable for use in the shack as well. What a pleasure to push a switch and instantly read the state of charge of your battery. It's also great to have automatic shutdown and charge maintenance without time- or record-keeping. The per-charger was designed for the usual 8-cell 9.6-volt pack but is easily modified for another configuration. It incorporates a circuit—Z2-TR1—to protect the HT (which can be used while on charge) from voltage spikes or component failure. It also has a manual override to allow careful charging of the really *dead* battery.

Construction was done on perfboard. The board was insulated from and attached to the chassis with two-sided adhesive tape. A 0-1-mA meter was used and the necessary shunts were made as follows: The 100-mA shunt, with a resistance of about .8 Ohms, was made by winding 57.25 inches (145.4 cm) of #32 AWG enameled copper wire on a 2-Watt 1-meg resistor or other suitable insulating rod about ¼ inch in diameter. The 600-mA shunt, with a resistance of about .13 Ohms, was made by winding 23.4 inches (59.4



HT auto per-charger.



Component layout.

cm) of #28 AWG enameled copper wire on a similar form. The shunts may be checked with a test milliammeter in series with the charger and a battery, in case of slight irregularities in wire size, etc. If the charger meter reads too high, the shunt wire is too long. If the reading is low, the shunt wire should be lengthened slightly.

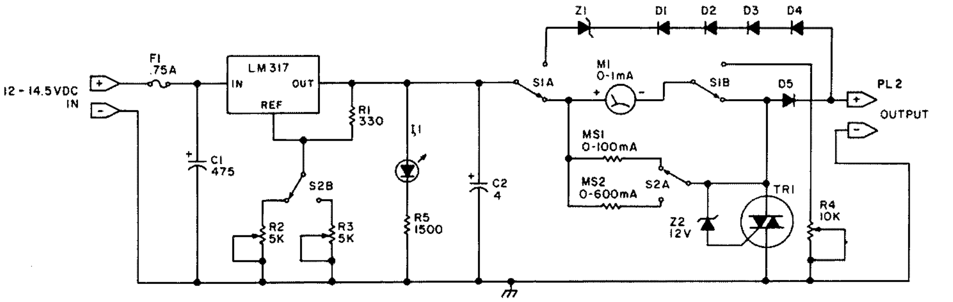


Fig. 1. Circuit schematic.

The percent meter is easily calibrated. With S1 thrown to the percent position and S2 to the high-range (manual) position, attach a voltmeter from PL2 to ground. Temporarily strap J1 to the regulated output at S1a. Adjust R3 for an 11.2-volt reading on the test meter and adjust R4 for a full-scale reading on M1. Then adjust R3 for an 8.4-volt output and check M1 for a zero reading. If necessary, add or subtract diodes in the D1-D5 string to correct this zero reading. Recheck the full-scale reading. Any combination of zener and silicon diodes that will reach 8.2 to 8.4 volts at the M1 meter is acceptable. Throw S1 to the mA position, S2 to the 100-mA position, and set R2 for 11.2 volts at J1.

The TR-2400 has no diode in the battery circuit in the transceiver. If your HT has one, as has the Tempo S1, strap it out and install a diode in the positive cable lead of the wall charger to maintain the input voltage properly. Do not open the wall charger case. Be sure to check your battery specs for the proper charging rate. When starting a charge or when using your auto percharger with a dead battery, always use the high-scale (manual) position of S2 until you are sure that the current has dropped to a safe value, then you may shift to the taper (100-mA) position.

Use the center OFF position of S1 when plugging in or unplugging your HT. The percentage of charge can be checked at any time.

Any 13.8-volt supply can be used, or, if mobile, the cigarette lighter socket is a convenient source of power.

If you have 2 batteries for your rig, extend their life by using one until it is discharged to the zero point on M1, then fully recharge it while using the other. We have found the HT auto percharger to provide the utmost in convenience while using the HT mobile or portable. ■

Immortalize Your IC-2AT Battery Pack

Why waste your nicads when you're in the car? Build this miniature power supply and your batteries will last forever.

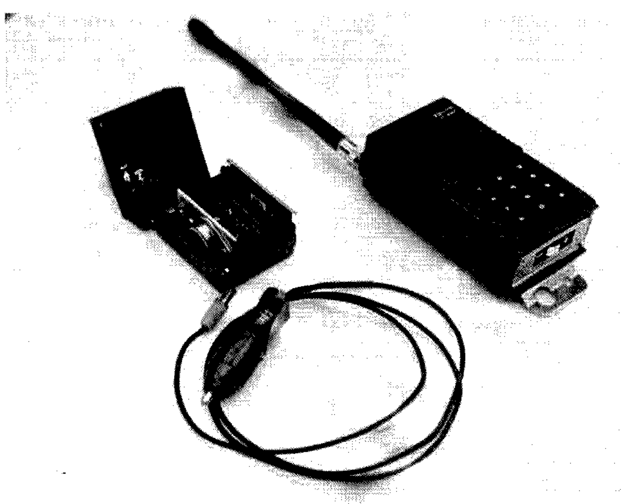
It wasn't long after I received my Icom IC-2AT that I realized the limited battery life of the pack supplied with the unit (BP-3). The pack is rated at 8.4 V @ 250 mAh, which is relatively marginal for the power output of the unit (1.5 W and .15 W). Since most of my transmissions are made while in the car, the idea of saving my batteries for utilization outside the car became extremely attractive. The solution then was either to get an Icom IC-CP1 cigarette lighter recharger for the BP-3 or do something else. The solution of using the lighter charger is simple, though in the long run you pay a penalty; that is, there is no sure way of making the transceiver draw power from the lighter or the battery. It is normally a joint effort since the lighter plug, because of the current-limiting capabilities, can't supply enough power when transmitting. The result is that you reduce the power being drained from the battery pack, but it is not eliminated.

After attending the Hamburg, New York, hamfest, I was able to acquire an IC-BP-4 battery pack for the 2AT. This is nothing more than a case without batteries which is able to accept six AA nicads for a total voltage of 7.5 V at 500 mAh. Icom rates the output of this pack at 1 W or .1 W, which is too little for comfort. So the idea of putting a regulator inside this battery pack and giving the IC-2AT 11.3-V, 1-Amp capability became extremely attractive. By the way, with the above voltage of 11.3 V, the 2AT pumps out a solid 2.8 W or .28 W depending on the power switch on the unit.

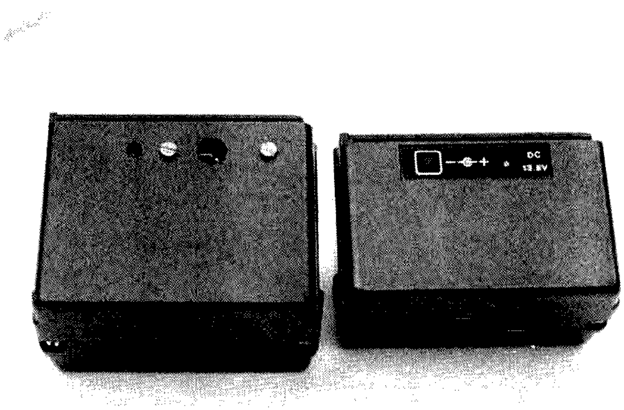
Having my concept reduced to practice was extremely simple. The circuit is shown in Fig. 1. All it is is a simple regulator set at 11.3 volts with a crowbar network just in case the regulator dies (so that it doesn't kill my transceiver). According to the folks at Icom, the unit is capable of sustaining a voltage of 12.5 V; any voltage above that might or might not make your 2AT a piece of history. So why take a chance?

The Circuit

Power is obtained from the lighter plug in my car. The 12 to 15 volts are then



New battery pack and power cord with the IC-2AT.



New pack on left, standard pack on right.

filtered by C1; this is a good practice since ignition noise and generator whine could cause problems later on. The combination of R1 and D4 is just an indicator to tell me when I do have power coming into the unit. Since I drive a car in which all systems are switched off by the ignition, this feature is very convenient. The regulator used is a 5-volt unit that is "lifted" above ground by the zener diode, D1 (a 6.2-V zener), to give us roughly 11.3 volts. The normal sinking current of the regulator is about 4 mA, surely not enough to bias the zener, D1, outside the conduction knee, so another 22 mA of biasing current is provided from the R2 resistor. This gives us a very clean zener voltage of about 6.3 volts. The crowbar circuit is very simple and is made to kick in at 12 volts. When the output voltage reaches 12 volts (it should never do that if your regulator is working properly), it turns on the zener diode, D2, which generates enough voltage across R3 to set the SCR into conduction. This SCR will essentially short the output voltage, thus blowing the 1-A fuse.

Construction

First remove all battery clips from the inside of the BP-4 pack. Cut a piece of aluminum 1-7/8" long by 1" wide. Drill holes to mount the TO-3 regulator. You can then mount this regulator vertically by simply using L-brackets or Super Glue against one side of the plastic battery guide. On the second rail from the bottom, mount the terminal strip (you should cut the two corner lugs from this 5-lug strip). All wiring is done between the lugs and the legs of the regulator. The input capacitor and crowbar circuit are mounted in the first rail with the fuse on the center rail. Do not use a fuse holder; just solder to the fuse ends and route the fuse accordingly. On the lid of the housing and using the belt-clip holes designed to provide power to the BP-3, drill a 1/4" hole and 1/8" hole for the LED indicator. Mount the coax power jack using two screws (if you can find No. 2 screws and nuts, that's ideal; otherwise you must go with No. 4). The lid and the main battery pack are connected with two color-coded wires.

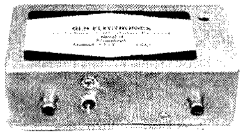
Check-Out

Connect a power supply providing 14 V dc to the input of the unit. The output should read 11.3 V dc. Now increase this voltage to 16 volts and check for the output voltage to be at 11.3. Your unit is now ready for testing on your IC-2AT.

I have used this unit for three months now and it functions beautifully. Since I do operate sometimes from fringe areas, I drive a little amplifier located in the back of my car that takes my 2.8 W and makes them 40 W. Such an arrangement is very desirable, since when leaving the car the radio is put on my belt and the amplifier is in the trunk out of sight. To say the least, there are no worries about something being stolen.■

HIGH PERFORMANCE PRESELECTOR-PREAMP

The solution to most interference, intermod, and desense problems in **AMATEUR** and **COMMERCIAL** systems.

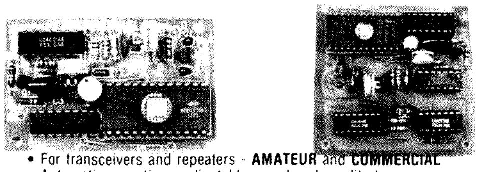


- 40 to 1000 Mhz - tuned to your frequency
- 5 large helical resonators
- Low noise - High overload resistance
- 8 dB gain - ultimate rejection> 80 dB
- 10 to 15 volts DC operation
- Size - 1.6 x 2.6 x 4.75" exc. connectors
- **FANTASTIC REJECTION!**

Typical rejection:
±600 Khz@144 Mhz: −28dB
±1.6 Mhz@220 Mhz: −40dB
±5 Mhz@450 Mhz: −50dB

Price - $69.95 bipolar w/RCA jacks
Connector options: BNC $5, UHF $6, N $10
SUPER HOT! GaAs Fet option $20

AUTOMATIC IDENTIFIERS



ID-1
ID-2

- For transceivers and repeaters - **AMATEUR and COMMERCIAL**
- Automatic operation - adjustable speed and amplitude
- Small size - easy installation - 7 to 15 volts DC
- 8 selectable, reprogrammable messages - each up to 2 min. long
- Wired, tested, and programmed with your message(s)

Model ID-1 - $39.95 Model ID-2 w/2 to 10 minute timer - $59.95

We offer a complete line of transmitter and receiver strips and synthesizers for amateur and commercial use.
Request our free catalog. *Allow $2 for UPS shipping - Mastercard and VISA welcome*

Unlock the New Electronic Mailboxes

MSOs are at the forefront of amateur radio's vast communications revolution. WB7QWG shows you how to tune in, log on, and not drop out.

Robert J. Foster WB7QWG/9
10126 Catalina Drive
Indianapolis IN 46236

As I sit here at my desk with pencil and eraser in hand working on this article, on the other side of the room my computer is happily keeping KB7SF (Gary—Butte, Montana) occupied in a rather active conversation on the teletype® segment of the twenty-meter band.

The computer at the moment is telling KB7SF the tale of how the English mathematician, Charles Babbage (1792-1881), might have ushered in the age of computerization with his invention of the Analytical Engine in 1835, had there not been a lack of government support.

The tantalizing details of Mr. Babbage's pursuits are just one of the information files contained in the trivia section of my Radio Shack Model III computer, acting as a host and responding automatically to user commands.

KB7SF is not the only station that has accessed the computer system this morning. In all, my mailbox contained messages from Connecticut, Florida, and Dee Why, Australia. Not bad operating for someone who has been working on projects other than amateur radio throughout the morning, with a little DX to sweeten the moment!

The MSO Mystery Revealed

The age of computerization has arrived on the amateur radio bands and has found its way into mailbox, or MSO (Message Storage Option), operations. Hundreds of amateurs are discovering the convenience of sending and retrieving message traffic, computer programs, and personal greetings through the computerized systems which are located on the bands.

The questions most often heard on mailbox frequencies are, "Where are the mailboxes?" and "How do I use them?" This article will end the mystery of the command structures used by the majority of the systems and also provide a listing of mailboxes and their locations. But let's not get the cart before the horse. Before you dive into the command structures of the mailbox systems, you need to have knowledge of the equipment in use.

The Hal MSO

There are two major suppliers of mailbox systems, Hal Communications Corporation of Urbana, Illinois, and Macrotronics Incorporated of Turlock, California.

Hal offers a dedicated system (it will operate only as a teletype terminal and message system). Macrotronics offers hardware and software packages for the Radio Shack Models I and III computers as well as for the Apple II or II Plus micros which allow the computers to operate on RTTY while still allowing the computer to be used for projects other than ham radio.

The stations that are using Hal equipment are easily identified when you are listening on the RTTY band, since it is the only machine that is programmed to respond with the key letters MSO in its output. The Hal system sits passively on a frequency waiting to be activated with an access code. Normally this code is a combination of the letters MSO and the last three characters of a station callsign (e.g., the access code for K4KOZ is MSOKOZ). Once the MSO is activated, it comes alive with a distinctive message.

Note: Access code needed to activate MSO operation. Always begin commands after a carriage return/line feed (CR/LF) at far left-hand margin and preceded by a period.

.HELP Provides summary of MSO3100 commands.
.DIR MSO transmits directory of stored messages including Filename, Date, Time Created, Byte Size of messages, and Security Status.
.SDIR Gives short version of directory with name and Security Status of each stored message.
.READ Must be used in conjunction with the filename of the message you wish to read, i.e., .READ MESSAGE#1 will prompt the MSO to transmit the file entitled MESSAGE#1. You must use the exact listing for the file as written in the directory.
.WRITE Used to write a message for future storage in the MSO. Must be used in conjunction with the filename you wish to list in the directory, i.e., .WRITE MESSAGE#2 (CR/LF) THIS IS A TEST MESSAGE. would prompt the MSO to hold a message entitled MESSAGE#2 and its contents for storage.
.ENDFILE Causes message (from .WRITE above) to be stored. MSO responds with confirmation message.
NNNN Alternate End of Message Flag. File previously written will be stored, but confirmation transmission from the MSO will not be issued.
.DELETE Must be used in conjunction with filename to remove file from storage area, i.e., .DELETE MESSAGE#1 (CR/LF) will delete that file.
.FILEHELP Shows examples of command format.
.QBF MSO responds with two lines of QUICK BROWN FOX.
.RYS MSO responds with two lines of RYRY.
.EXIT Used at the end of contact with MSO to disable MSO functions. The next user will then have to open it with the access code.

Security Status of files are classified as either OPEN, READ, or PRIVATE. OPEN messages may be read or deleted by anyone. READ messages can be read by anyone but deleted only with a password. PRIVATE messages may be read or deleted only with a password.

There also are references made to special commands used for control of peripheral equipment (KY1ON, KY2OFF, etc.). These commands shouldn't be used until you know what they control. Contact the SYSOP for details, as the functions are all user defined.

There also is a command to turn the MSO printer on and off (PRINTON, PRINTOFF), which is handy to leave messages to MSO owners...but once again the system may or may not be set to respond to the command, so check with SYSOP first.

Table 1. MSO3100 command structure.

A command sequence is needed to access the Macrotronics systems. (See text and Table 4.) Since many of the computer systems are using "autostart" demodulators, it is suggested that all commands be preceded with a series of RYRY to open the system. A common practice is to send "RYRYRYR DE CALLSIGN (Command) (CR/LF).

TRS-80

Filenames on the TRS-80 mailbox systems are allocated by the system operator. Users can read or write only to existing mailbox filenames.
(Command Sequence)W(CR/LF) Mailbox responds with an ID format.
(Command Sequence)D(CR/LF) Mailbox responds with a listing of all mailbox message filenames.
(Command Sequence)P(Filename)(CR/LF) Transmits the filename specified in the command. Filename must be exactly as it is written on the directory.
(Command Sequence)M(Filename)(CR/LF) Opens the specified filename for insertion of message traffic. To close mailbox at end of message send NNNN.
(Command Sequence)I(CR/LF) Transmits instructions to new users.
(Command Sequence)R(CR/LF) Opens mailbox system for relay mode. Any material transmitted into the mailbox will be replayed. To end input of material for relay transmit NNNN.
(Command Sequence)C(Filename) Clears all messages stored for that filename.

APPLE A6500

There are some distinct differences between the Apple A6500 software and the rest of the Macrotronics line. The A6500 allows user stations to write their own filenames, whereas the TRS-80 systems do not.

The A6500 does not have a Relay Mode. The R command is for recording messages to the disk system, and the format is slightly different (a space between the command letter and filename).

The command letter for a directory listing is Q on the Apple system.

Finally, the A6500 command letter for deleting old message files is D and not C as in the case of the TRS-80-based systems.
(Command Sequence)W(CR/LF) Mailbox responds with ID format.
(Command Sequence)Q(CR/LF) Mailbox lists all filenames of current messages.
(Command Sequence)P(Filename)(CR/LF) Transmits specified filename as listed on directory.
(Command Sequence)R(Filename)(CR/LF) Opens system for input of filename you specified. Continue with message, ending with NNNN.
(Command Sequence)D(Filename)(CR/LF) Deletes the filename specified from the mailbox system.

Table 2. Macrotronics command structure (TRS-80 and A6500).

To identify Hal equipment, watch for a message format that looks like the one in Fig. 1. The identifiers of the Hal system are the MSO and commands that are preceded with periods.

The equipment behind that message is a Hal DS3100 ASR Communications Terminal with the MSO3100 Message Storage Option, a fairly spectacular-looking microprocessor-controlled package that operates just as good as it looks.

The DS3100 ASR was introduced in 1979 and the MSO option followed about one year later. The concept of having the MSO option was gleaned from a lot of two-meter activity around the Hal plant and just "sort of grew into the MSO," according to Bill Henry, director of Hal Communications Corporation. The MSO option has met with more popularity than he originally dreamed of, he said.

Although the DS3100 terminal has been popular in its own right, Hal has sold 400-500 of the MSO options. Some of the units, however, have been placed in commercial or government use. FCC field offices use the Hal MSO system for their internal teletype communication circuit between field offices.

The command structure for the Hal MSO was designed to follow some disk-operating systems, and according to Hal officials makes the chance of accidental triggering almost nonexistent. Learning the various commands needed for using the MSO is fairly straightforward, and a few minutes of study is all that is needed to become an expert.

Macrotronics Mailbox

Macrotronics equipment is varied and widely used, since they have been producing software/hardware packages for home computers since 1978. The earliest success, according to Ron Lodewyck N6EE, president of Macrotronics, was the M-65 interface board and software that was developed for the PET computer. Shortly afterward, units for the TRS-80 Model 1 (M-80) and for the Apple computer (A-650) were produced.

As time progressed, so did sophistication of the programs and the interface units produced by Macro-

Gaining access to the Super-Ratt-operated system is accomplished through a "log in" sequence. Normally the access code to open the system is the callsign of the host station preceded by a colon, i.e., :K1VYQ, and followed by a carriage return. Once the machine is opened, user stations are asked to "log in" with their callsign, once again preceded by the colon and followed by a carriage return which establishes commands versus "chatter."

User commands include the following:

:(TURN ON COMMAND) Normally the station callsign. Activates the bulletin-board function.
:ENTER Turns on receive-copy buffer for incoming message.
:END Sent at end of message into copy buffer. Prepares system to SAVE, CANCEL, or LIST.
:LIST Causes transmission of text stored in copy buffer.
:CANCEL If after LISTING message you wish to cancel it without SAVEing, this will remove text from copy buffer.
:SAVE Causes text in copy buffer to be written to disk, then computer asks for a filename for the directory. Filename must be preceded by a colon and followed by a carriage return (no more than 30 characters).
:READ (number) Causes message (number) from system directory to be transmitted, i.e., :READ9.
:KILL (number) Deletes a message from system.
:HELP System transmits short listing of message commands.
:COMMANDS Causes complete listing of commands to be transmitted.
:WEATHER System transmits weather file as prepared by SYSOP.
:NEWS Transmits news file as prepared by SYSOP.
:TIME Reads current time from system clock and transmits.
:DIR Sends directory of message file numbers and names.
:LOG Transmits log of system users since last log update.
:BYE Exiting code from system. Resets system to normal operating parameters.
:USER Activates special functions programmed by SYSOP. May not be in use.
:SYSOP Causes Apple speaker to "beep," alerting SYSOP of problems.
:EXPERT Bypasses longer system prompts.
:RYS System sends string of RYRYRYRY.
:QBF Causes string of QUICK BROWN FOX to be transmitted.
:ASCII Switches to ASCII mode and sends line of RYRYRY.
:BAUDOT Switches to Baudot code; sends line of RYRYRY.
:45BAUD Changes speed to 45 baud.
:74BAUD Changes speed to 74 baud.
:110BAUD Changes speed to 110 baud.
:110ASCII Places machine in 110 ASCII.
:TAPEON Activates game I/O to turn on audio tape recorder. May not be used on all systems.
:TAPEOFF Turns off tape recorder.
:C/RON Activates 72-character carriage return.
:C/OFF Turns off auto carriage-return function.
:INPUTA, :INPUTB, :INPUTC, :INPUTD If these commands are utilized, special analog data input may be transmitted from instrumentation custom-installed by individual station owners, i.e., current temperature, S-meter reading, etc. It is best to check with system operators on these commands.

Table 3. Super-Ratt command structure (Apple II).

Software	Interface	Computer
M8000	M-80	TRS-80 Model I
M8300	M-83	TRS-80 Model III

Fig. 2. Macrotronics units.

tronics. Their latest entry on the market is the Terminall, which interfaces the TRS-80 Models I and III as well as the Apple computer to the world of amateur RTTY operation. As this article was being written, mailbox software for the Apple version of the Terminall was not available. "Not yet," Ron Lodewyck said, implying that mailbox service for Apple owners who have the Terminall is in the works.

How the original idea developed for computerized on-the-air mailboxes is a little hazy. Macrotronics is quick to admit that the idea was presented to them by an amateur radio operator who desires anonymity, and some of the base ideas for the system came from that unknown individual. (I personally thank that unknown for the concept.) Another ham who was in on the earliest stages of experimentation of mailboxes was Irv Hoff W6FFC. Although Hoff and others weren't using the Macrotronics equipment at the time, many of the operating procedures and even the current command structure for the Macrotronics mailbox systems can be traced to their early twenty-meter activities.

The interface/software packages that do support mailbox operation from Macrotronics are numerous—see Fig. 2. The A650 and A6500 combination has been discontinued by Macrotronics, but some of the units are still on the air and around flea markets. The Terminall for the Apple soon will fill the void left by the discontinuance of the A650.

Macrotronics has sold about 1000 of the mailbox systems, with the models for the TRS-80 computer outselling Apple about 2 to 1. Some of the units have found their way into commercial and government use, with NASA being listed on the Macrotronics-owners list.

Command structures for the Macrotronics systems at first seem to be a little bewildering, but with a few moments at the keyboard accessing some mailbox station, the brilliance behind the structure can be recognized. Macrotronics systems use a combination of a command sequence and letter of the alphabet to tell the computers what function is desired. The command sequence is the variable in each station's operation and is normally the last three letters of a callsign followed by the letter Z. (In my case, my call is WB7QWG and the command sequence for my mailbox is QWGZ.)

Recognizing the Macrotronics system is easy when tuning the bands. The stations invariably end each transmission with a sequence of four Ns—NNNN. This is a standard termination code for the Macrotronics-programmed computer, indicating that no further action is anticipated without another command.

Custom Cuties

In addition to the two major suppliers of mailbox systems, you will find a number of customized stations on the air. Operating systems range from home-brewed computers and CP/M-based software for business machines to Apple Basic.

Some of the stations are fascinating. I have logged a German station operating on 15 meters that called for contacts automatically, logged you in with a QSO number, and gave you an RST report—all without hands-on support from its originator! (And seemingly without the constraints of FCC rulings!)

Another computerized mailbox on 40 meters operates on ASCII, filled with Microsoft Basic programs that can be spooled into your personal computer!

Most of the systems that have been logged here, though, follow command structures that have been in use by Hal and Macrotronics. Learning how to use

Table 4. Mailbox directory.

these two systems will make entry into the custom stations a lot easier.

Speak to Me, Computer!

Tables 1 and 2 list the command structures for the Hal and Macrotronics systems. Studying the information in the tables will ease your entry into the mailbox crowd. But some hints are in order at the same time.

Keep in mind that the mailbox frequencies will have a number of users and that someone far distant from your station that you can't hear could be accessing the mailbox. Always wait a couple of minutes before you start transmitting, since you could interrupt someone's RTTY artwork that he is depositing in a mailbox. (You don't know anger until you have "hit" some temperamental artist halfway through his ten-minute masterpiece!)

Most of the mailbox systems are crystal-controlled and depend on stable frequency for good reception and transmission. Experiment with the tuned frequency on your dial and center exactly on the host station before sending material into it.

Be sure that when you leave a mailbox system you don't leave something active that will cause heartburn for the system operator. It's considered bad form to open a mailbox and then leave it absorbing everything on the frequency and creating a two-zillion-bit message of garbage!

Keep in mind that the regulations regarding proper IDs apply. You and the mailbox must identify according to current rules.

To save time in mailbox operations, go "off line" to compose your message onto tape or disk or memory, and then return to the mailbox to send your traffic. Standing by with some hot traffic waiting for a 10-word-per-minute hunt-and-peck artist to finish with his painful pecking on a 100-word-per-minute machine can be exasperating.

There are some distinct differences that you will find going from one mailbox to another, since so many of the stations have added custom features such as baud-rate changes or switching between ASCII and Baudot. Study the basic instructions contained in the tables and then monitor mailbox operations for awhile to see the differences between one machine and another.

Where to Find Them

Mailbox systems are popping up on all of the active amateur bands, but most of the activity seems to fall on the 20- and 40-meter bands. Table 4 lists some of the stations of which I currently have knowledge. The listing falls far short of being complete, and I would like to hear from system operators whose stations aren't listed. Perhaps an update of a "mailbox directory" will be possible in a few months.

Some of the more active mailbox systems include WA1IUF (Jerry—New Haven, Connecticut) and WA1URA/4 (Frank—Miami, Florida), located on 14.097.5; there are many stations, including KØVKH (Dick—Rapid City, South Dakota), on 14.087.7; and K4CZ operates a station on 7098.5 that seems to be easily the most popular operation on 40 meters.

WA1IUF and WA1URA were among the first computerized systems on the air with the Macrotronics line in 1978. Since that time they have logged in a lot of stations that check in daily, and the frequency "network" has stretched from Europe to Australia. VK2BHF (Horst—Dee Why, Australia) is one of the newest stations to show up on that particular frequency.

The Mailbox Future

Undoubtedly not wishing to let any marketing secrets out of the bag too early, both Macrotronics and Hal were sketchy in their descriptions of future plans in the computerized mailbox area.

Hal responded to "What's in the future?" with the fact that they are concentrating on a new version of the MSO system that will be ideal for traffic handlers and MARS applications. The new system (Hal TRO3100) will collect and store message traffic, allow

easy editing of the messages, allow rearranging of the messages in whatever priority is needed, and then transmit them.

Macrotronics evidently has a number of irons in the fire, but as Ron Lodewyck pointed out, the development time for the software is enormous. Approximately two man-years of time was devoted to the original M8000 program, so future editions of the mailbox and RTTY programs for computers will take awhile.

One interesting note from Macrotronics was a reference to the Atari 800 and 400 computers and the fact that they seem to be the cleanest computers from an RFI standpoint; progress is being made for software for those computers.

The future of RTTY and new modes of error-free communication also were discussed. AMTOR and Packet Radio undoubtedly will find their way into mailbox/MSO systems and general data transmission.

While those companies that have been providing systems in the past continue to upgrade and market their mailbox systems, new entries are being made in the amateur radio market. Universal Software Systems, Inc., of Ridgefield, Connecticut, just released the Super-Ratt program for the Apple computer which is causing some heads to turn on the mailbox frequencies.

Not a package system, Super-Ratt is the software to drive an Apple II with 48K of RAM, Applesoft Basic in RAM, and at least one disk drive. The Radcom RTTY card is supported, or some other type of TTL-compatible terminal unit may be used through the Apple game I/O.

Super-Ratt combines most of the desirable features found in older systems with some new functions found only in the Ratt-Soft program. What kind of features? You name it! How about automatically including the temperature and humidity conditions around the shack location? Analog-input capability of the Super-Ratt leaves your imagination to devise new functions. In all, some 33 commands are available in the Super-Ratt bulletin-board mode, with other routines available to the system user (see Table 3).

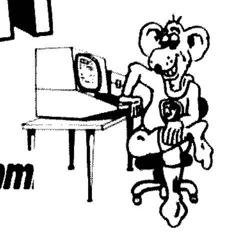
A very unique feature of the program allows error-free file transfers between two Super-Ratt stations. After being placed in the transfer mode, the two station's begin transferring data, with the receiving station's computer verifying line-oriented check sums of each line, acknowledging error-free reception, or requesting a repeat of the material. The two computers "handshake" the file being transmitted until it is finally received error-free.

Although the Super-Ratt is currently available only for the Apple computer, Bill Barrett of Universal Software reports that software for the Commodore 64 and TRS-80 Models I and III will be available in a few months.

I see a trend toward specialized mailbox systems springing up across the country. As with computer bulletin boards accessed through telephone lines, people with specific interests can start exchanging ideas on ham-radio mailbox systems. In fact, I have a healthy interest in the TRS-80 and mailbox systems. As a starter, let's list my mailbox on 14.097.5 as the "Mailbox-Mailbox."

Will be looking for you on twenty meters! ■

SUPER-RATT™



The Complete RTTY Communications Program for the Apple II

ONLY $59.95 POSTPAID!

- Full Radio Bulletin Board System™
- Verified File Transfer™ assures error-free communication
- Works with all conventional tuning units
- 75 pages of documentation
- "Open" Program—easy for you to modify

How E.T. Really Called Home

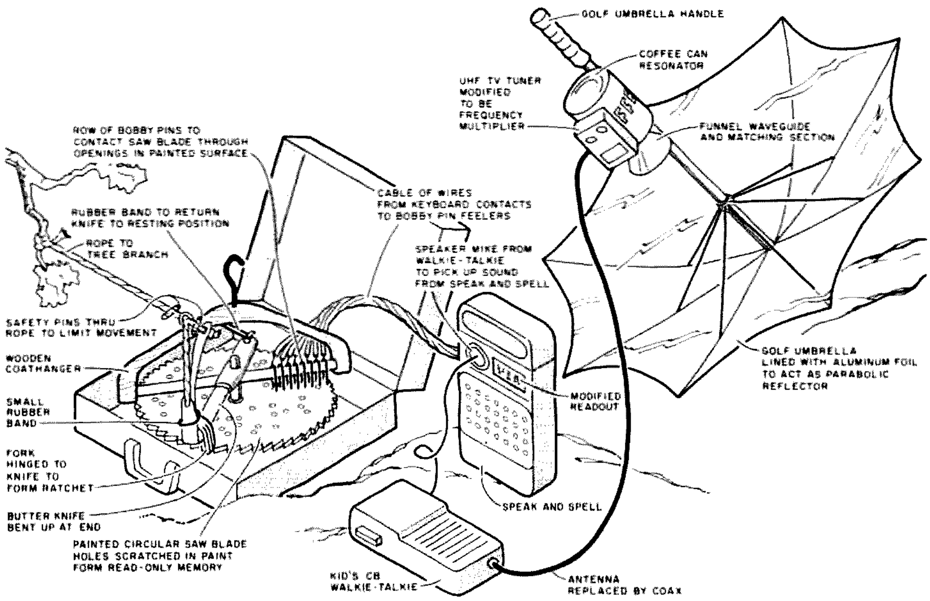
If it were not for an inventive ham, E.T. might still be trying. In this exclusive article, the designer of the little guy's communicator unveils its inner workings.

Henry R. Feinberg K2SSQ
415E 85th Street
New York NY 10028

"TGIF," I thought as I returned from lunch to my office in the exhibit department of Bell Labs. Lying on top of my desk—on top of a pile of exhibit plans—was a telephone message asking me to call Kathleen Kennedy in Hollywood. Now, the public relations department of Bell Labs gets many requests for information, but this one was considerably more unusual than most.

Ms. Kennedy, who produced *E.T.* with Steven Spielberg, had called Bell Labs earlier that day to find someone who would work at home during the weekend, designing a space communicator to be used by a stranded alien to contact his space ship. Few other details were given, as a great deal of secrecy surrounded the film. Even the name of the film was a secret. I was told that the alien was called E.T., short for extra-terrestrial, but the working title given me for the film was deceiving; it was called "A Boy's Life."

I guess the call was referred to me because of my experience in using household objects to explain science. My title at Bell Labs at the time was Exhibits and Science Presentations Coordinator. Before coming to the Bell system, I worked with Don Herbert, TV's "Mr. Wizard," designing experiments using everyday materials to explain scientific principles. At the Labs, I continued my work popularizing science through films, demonstrations, and exhibits. Currently, my work at AT&T involves corporate exhibitions such as the Bell System's Futurecom at Epcot Center in Walt Disney World.



Pictorial drawing of the E.T. communicator.

Kathleen Kennedy asked me to work by phone with Melissa Mathison, who was writing the *E.T.* script and who was also associate producer. I had several long phone calls with Melissa, discussing items found around the house that could be used in a communicator. As an avid ham-radio operator with a limited junk box, I first looked for household objects that could actually transmit a signal. Transmitters of various sorts were too ordinary, of course. I was looking for something more exotic, something like a microwave oven that could be converted to send a signal into space.

Plausibility was a big fac-

tor. While the communicator didn't actually have to work, I wanted it to be plausible enough that my ham friends at Bell Labs wouldn't laugh me away from the "ham table" in the cafeteria. I also wanted to avoid a science-fiction look with a lot of blinking lights, coils, and sparks. It was important to me that people seeing the film would not be scared away from the science, and might even understand how a communicator like this might work.

Using a microwave oven as a transmitter seemed plausible enough, and I expanded on the fanciful design by placing a round hubcap in the oven to focus the microwave energy out the door and into a waveguide made of flexible aluminized air-conditioning duct. The duct could be run out the kitchen window to an antenna made by inverting a metal patio umbrella and using it as a parabolic reflector.

At this point, before I'm accused of gross ignorance for failing to recognize how the oven would be de-tuned or how inefficient the system would be, remember that the objective was plausibility, not practicality. It was the thought that counted, and I was having fun thinking of possibilities such as building a flying spot-scanner using a combination of mechanical and electronic components—like Christmas tree ornaments and loudspeakers with mirrors attached. Melissa Mathison told me that Steven Spielberg liked the microwave oven idea but wanted a portable unit to work from a forest clearing. Back to the drawing board.

During my years with Mr. Wizard, we put together one Rube Goldberg contraption after another to illustrate scientific principles. Invariably, we would use household materials in unorthodox ways. Psychologists call this type of creative brainstorming a release from

The E.T. communicator. (Photo copyright © 1982, Henry R. Feinberg)

"functional fixedness." Briefly stated, it means that you can do more with an old 813 than build a lamp with it. The trick is to analyze the desired result by function, breaking down each section to as simple a scale as possible; then it's easier to build the unit from the ground up in a new way. (Sounds a lot like writing a computer program, doesn't it?)

What Spielberg wanted was a beacon transmitter—something to say "Here I am! Come and get me!" I reasoned that three main parts were needed for a basic beacon: a means of producing a message, a programmer to repeat the message, and a way of transmitting the signal into outer space.

Working backward, I knew that a golf umbrella lined with aluminum foil would make a plausible-looking parabolic reflector. And on my last trip to the Dayton Hamvention, I saw coffee cans being used as resonators for receiving MDS TV signals. In fact, a UHF TV tuner purchased there *could* be extensively modified to act as a multiplier to select the umpteenth harmonic of a CB signal from a toy handie-talkie. The resulting microwave signal *could* then be directed from the coffee-can resonator toward the umbrella reflector through a waveguide/matching section made from a funnel. Ah, the license of plausibility!

To produce the message, I used a Speak and Spell™ learning aid made by Texas Instruments. The unit contains a speech synthesizer, a keyboard, a flourescent readout, and a speaker. E.T. deserved his own alphabet, so I rewired the segments of the alphanumeric readout. It took several tries to make the resulting gibberish look like another language. No changes were made in the speech circuits since I thought the sound-effects people would add their own sound. Actually, they never did, and in the film one doesn't hear any sound at all from the communicator—not even the original "message" I devised with the help of Debbie, my wife. It was our names repeated over and over.

The remaining problem was how to program the Speak and Spell to repeat the same message over and over. To begin with, wires were attached to each keyboard contact. A set of feelers was needed for the other end of the wires. Originally, I used a row of safety pins inserted through the dowel of a wooden coat hanger. But these were a problem to keep straight under pressure. Debbie deserves the credit for suggesting bobby pins. Their flat cross-section prevented them from moving sideways.

The coat hanger was positioned across a child's record player. On the turntable, a circular metal saw blade took the place of a record. The surface of the saw blade was coated with several layers of spray paint which served as insulation, preventing the bobby pins from contacting the metal blade. The message was programmed on the blade by carefully scratching through the paint. This created a pattern of openings similar to those on a punched card through which selected sets of bobby pins could make contact with the blade as it turned.

But how to turn the saw blade? Well, since the com-

municator was to work by itself in the forest and saw blades have teeth, I decided to use wind power to rotate the blade via a ratchet mechanism. A knife and fork were hinged together and made to pivot on the spindle of the turntable. Each back-and-forth motion of the knife and fork pulled another tooth of the saw blade around and created another set of contacts. A rubber band returned the knife between pulls. A string tied between the knife and a nearby tree branch was all that was needed—the rest was a breeze!

How were the electronics powered? As Melissa Mathison rationalized it, E.T. came from an agrarian society that had learned to tap the forest for electrical power. On the set, the day's shooting schedule didn't leave time to wire the trees, so a battery was used. Score one for practicality over plausibility.

The close-ups of the communicator were filmed in a sound stage dressed to look like the forest. To achieve a misty quality, the trees were sprayed with water before each take. Everything was damp, including the boulder on which E.T. placed the Speak and Spell. At one point, the bare circuit board made contact with the wet surface and it stopped working. Panicked thoughts of zapped ICs flashed through my mind as all eyes turned to me for help. I was scared, but I said a silent prayer and asked for a hair dryer to be brought onto the set.

There's a scene in the film where Elliott helps E.T. set up the communicator in the forest. As the wind starts to blow, Elliott shouts, "It's working! It's working!" I remember that scene, because I was standing right next to the camera, wiping my brow and mouthing the same words. ■

Buyer's Guide to Dayton

From securing accommodations to planning your expenses, WA4BPI helps you make the most of your Hamvention buck.

Is this great hobby called ham radio starting to get you down? Maybe you've had your fill of QRM and the woodpecker and you're ready to swap your low-band rig for a set of golf clubs?

Don't worry. It's not the end of the amateur radio world for you. It's something we all go through at one time or another. It's just a time to find a new phase of the hobby to jump-start your interest in ham radio again. And the biggest pulse of charging current in ham radio is just around the corner—on April 29, 30, and May 1, the dates for the 1983 Dayton Hamvention.

First, let me say that I don't have any ulterior motives for writing this article. I don't live in Dayton, Ohio, I'm not a member of the Dayton Chamber of Commerce or of the Dayton Amateur Radio Association, I don't have a vested interest in the Dayton Hamvention, and I don't even have relatives living in Dayton. I just love their hamfest and look forward to it every year. The purpose of this article is simply to pass along some of the things I've learned after attending the Hamvention many times. Hopefully, what I've learned can help you improve your annual trip to Dayton (if you've been before) or, if you've never been, to encourage you to attend and get in on the fun.

Transportation and Accommodations

Most years that I've attended the Dayton Hamvention, I've traveled in private vehicles, but many others fly (it's almost 500 miles from where I live) and still others, I imagine, have taken the train.

The first year we traveled in a Winnebago and, as nice as that was, there were a few drawbacks. The RV route can be troublesome, depending on the size of the group and the people that make up the group. If you've been on trips before with the folks and get along well, the chances are that you'll enjoy a trip to Dayton with them in the RV. But even a husband and wife have arguments, so it's best to make sure you have a congenial group since you'll be sharing some close quarters for a few days and nights.

RVs are also a problem in that unless you have a second vehicle you have to unpack everything when you get to camp and hook up water and electricity, and then repack and unhook everything to drive to the Hamvention. Driving the RV and finding a place for it at the Hamvention parking lot also can be a grueling situation even with the help of the many courteous parking lot attendants. A car is a lot easier to maneuver in tight spaces.

Icom promoted its concept of "The World System" with its exhibit at the '82 Dayton Hamvention. It was one of the largest exhibits among the 180 dealers with displays.

I've also stayed in a pop-up camper, and even though it was economical, the weather at Dayton in April is changeable; the weekend we camped out, the overnight temperatures dipped to the 30s and it was very uncomfortable sleeping in the cold.

With experience as my teacher, I've found that the best way to make the trip is to drive a car, stay at a motel, and share the car and room costs with two or three fellow hams. The Hamvention Housing Bureau can be a big help in locating suitable accommodations, so avail yourself of their services. A total of 38 hotels, motels, and inns work with the bureau to help you find a place to stay, so you have a wide selection of rooms and prices. But the Bureau works on a first-come, first-served basis and it's best to get your reservations in early. If you insist on waiting until the last minute, the deadline for reservation requests is April 1.

Why go the motel route if camping is cheaper? The

Seen at the Icom exhibit was this super-sized version of the company's popular IC-2AT handie-talkie.

One-on-one conversations with dealers and designers are commonplace at the Dayton Hamvention and give potential buyers an insight into new equipment and operating procedures.

answer is convenience. You have a substantial structure surrounding you when you stay in a motel or hotel and therefore are not at the mercy of the Dayton weather. Plus, you'll have clean sheets to sleep on, a clean room to come back to after a hard day of hamfesting, and you'll have your own private bathroom to use instead of having to share a campground latrine with all of the other hams who are trying to get to the Hamvention at the same time you are.

The motel room is also more secure than your typical RV or pop-up camper. It's not very comforting to leave the $500 bargain you bought at the hamfest Friday sitting in a tent or the trunk of a car for two days and nights while you are busy searching the flea market for other prizes. And you certainly can't lug the rig around the flea market with you for two days, can you? You can lock it up in a motel room and feel relatively secure. Even if the maid goes in the room to clean and sees your prize sitting there, chances are she won't know what it's used for and won't have any idea of its value. That makes a motel room a pretty good place of safety for a traveling ham.

Expenses

Now that you're convinced that you want to go and have picked your method of transportation and suitable accommodations, let's get down to the grass roots and talk about money. Using my own trips as an example: To travel approximately 500 miles one way and stay three nights in Dayton and then drive back, I've found you will need at least $100 for basic expenses such as gasoline, accommodations, and food. The gasoline and room allowances are based on splitting the cost with at least two other people (it's not much fun to go alone).

As far as food is concerned, it's probably best to keep that separate. If you do stay in a motel you'll have to eat out, and if the cost is left on an individual basis you can order according to your pocketbook. That way, if you want to save as much money as possible to buy that dream rig, you can live on coffee and crackers and save the cash for the really important stuff like a new handie-talkie. Plus, buying your own food will avoid an argument between you and your companions when the waiter brings the check and you try to figure out who ordered the watercress sandwich and who should pay for the extra cheese dip. Food prices are reasonable in Dayton and at the Hamvention, so don't worry. If you have the cash, you won't starve.

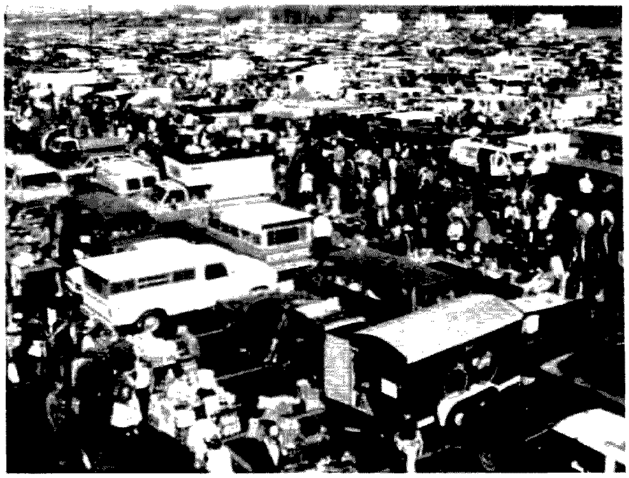
How to get the needed cash to pay for the trip is another problem. The best way I've found to raise the necessary capital is to sell some unused equipment. You could try to save up out of the regular budget, but in my case, extra money there is scarce. I know of some hams who sell equipment at their local hamfest and use the proceeds to pay for their trip to Dayton where they buy more gear to resell at their next local hamfest. It's a vicious but very successful circle.

Another way of making money is to rent a flea-market space at the Hamvention and sell some of your unused gear there. After all, 20,000 hams will be passing by your table over the three-day period of the Hamvention, so there's a good chance you'll find a buyer no matter how exotic the equipment is that you have to sell. And that means more money for you to put toward that item you've been searching for. Another successful circle, right?

The flea-market space also has other advantages. It's inexpensive when everyone in the group splits the cost, and it gives your group a meeting place to talk or simply to rest between raids on the flea-market vendors. Even if I wasn't going to sell, I'd still get a space just to have a place to rest and to locate the cooler. (Food prices at the Hamvention are reasonable, but you can beat the beer prices by buying your own.)

While I'm on the subject, the flea-market space is easier to handle if you take two cars to Dayton so that you have one vehicle to drive back and forth to the motel

Sellers meet buyers at the Dayton Hamvention. Shown here is just one of the three large rooms filled by dealers—over 180 at every recent Hamvention.



This bird's-eye view of the '82 Dayton flea market was taken with a wide-angle lens.

and another to leave at the flea market to hold your space for the next day. Last year we couldn't take two cars, and since we had to transport a Teletype® machine to sell, we rented a small trailer. We left that at the Hamvention to hold our flea-market space. The Hamvention has guards at the flea market overnight so there's no problem of theft, and that makes it okay to leave the equipment there that we haven't sold or gear that we've purchased to take home. Also, the trailer was cheaper to pull to Dayton than to pay for the gasoline and wear and tear on another vehicle.

The trailer also gave us a lot more room to carry equipment home and kept us from having to load down a car's trunk with a lot of gear. People who fly to Dayton may get there quicker, but if they find a super deal on a complete Collins station, they'd have to pass it up or pay extra for shipping. The airlines wouldn't classify the Collins as carry-on luggage, would they?

Clothing

I've seen the weather in Dayton shift from below freezing one day to clear skies and 70 degrees the next, so having the proper clothing for the climate is important. The key to dressing for Dayton is the old outdoorsman adage—dress in layers. That way, you can put on or take off clothing as the weather changes. Blue jeans are a basic of my Dayton wardrobe since we're usually too tired to dress up and attend the Friday night FM bash or the Saturday night banquet after running through the flea market and indoor exhibits all day. If you wish to attend one or both of these gala events, be sure to bring along suitable clothing.

But for dressing for the daytime activities, from the belt down, a standard pair of blue jeans, a pair of crew socks and some comfortable, sturdy shoes (that are good for lots of walking) are the prime items. From the belt up, let me suggest starting with a T-shirt followed by a long-sleeve shirt (you can roll up the sleeves if warm weather prevails), a sweater, and a waterproof or water-resistant jacket to turn back the wind and the rain. Also, carry a heavy, winter coat that can be left in the car so it's within reach should the weather take a turn for the worse like I've seen it do.

In addition, I wear a cap, something like a baseball cap, to keep rain and the skin-burning sunshine off my face, and I carry a tube of lip balm in my pocket. Last year the rain and cold weather stayed away, but the wind was crisp enough to leave everybody in our group with chapped lips after the first day.

Group Communications

As far as which radio to take along for communications, your trusty HT is probably all you'll need for staying in touch with the other members of your group. Despite all of the rf produced by 20,000-plus hams, we usually find a two-meter frequency that can serve as a standby. The HTs allow the group members to wander the flea market at will yet stay in touch in case somebody finds a super deal on an item that another member is looking for. The radio link is also good for bringing the group together when it's time to head back to the motel or campground. My HT and a speaker-mike make the perfect combination.

Activities

Planning is also very important once you get to Dayton and inside Hara Arena. As soon as your tick-

CHECKLIST FOR YOUR DAYTON TRIP

- Secure room reservations early, for the nights of April 29 and 30, and if you intend to arrive early on Thursday, for April 28.
- Purchase Hamvention tickets in advance and, if applicable, flea-market space permits.
- Have the members of your group committed to attend the Hamvention and determine your transportation requirements.
- Save enough money to cover the cost of the trip and to cover the cost of any planned purchases. Turn most of your cash into traveler's checks as these are readily accepted at the Hamvention and at the flea market. Personal checks are NOT a readily-accepted method of payment. If a dealer has a choice of a cash sale or taking a risk of accepting a personal check, he'll probably take the cash.
- Pack clothing necessary for your three- or four-day trip. Don't forget, the weather is very changeable.
- Arrange for time off from work if you're part of the laboring class.
- Make and carry a list of things you intend to purchase at the Hamvention. The abundance of equipment found at the Dayton flea market is mind-boggling and could make you forget what you came in there to buy.

et is punched, workers hand you a plastic bag that contains your copy of the Hamvention program. Take a moment to look through this booklet and note the days and times of the various forums and discussions. Check the ones you'd like to attend and try to plan your day's activities around the forum times. The flea market will be there for the duration, but those forums are a one-time thing. If you don't attend them when you can, you might regret it later.

Other Tips

If you want to get a flea-market space close to the building, you'll have to get in line Friday morning pretty early. Selling on Friday starts at noon but those holding advance flea-market permits are allowed to enter the area to set up beginning at 8:00 am Friday. We got into line at 6:00 am last year but had to wait until almost 9:00 to get through the gate. Still, we got a pretty good space, but you can't always depend on luck. Get there early and be sure to buy your permit in advance. It's cheaper that way, plus it lets you check out the bargains before the main crowd comes through the gate.

It's also a good idea to carry a small bag with you if you intend to purchase small parts. That way, resistor, plugs, and transistors don't get misplaced or crushed if you have no place other than your pocket to put them.

Now, if you can remember all of the suggestions listed, a great experience awaits you at the Dayton Hamvention. I'm sure there are a few things I might have overlooked, and there might be some other things you'll want to add because of personal preference, but what I've listed here should be enough to guarantee you a super time at Hamvention 1983. ■

Hara Arena and Exhibition Center — Dayton, Ohio

Meet your amateur radio friends from all over the world at the internationally famous Dayton HAMVENTION.

Seating will be limited for Grand Banquet and Entertainment on Saturday evening so please make reservations early. Banquet speaker is Bill Leonard, W2SKE, former president of CBS News.

If you have registered within the last 3 years you will receive a brochure in late February. If not write Box 44, Dayton, OH 45401.

Nominations are requested for Radio Amateur of the Year and Special Achievement Awards. Nomination forms are available from Awards Chairman, Box 44, Dayton, OH 45401.

For special motel rates and reservations write to Hamvention Housing, 1406 Third National Bldg., Dayton, OH 45402.
NO RESERVATIONS WILL BE ACCEPTED BY TELEPHONE.
All other inquiries write Box 44, Dayton, OH 45401 or phone (513) 849-1720.

Admission: $7.00 in advance, $9.00 at door. (Valid for all 3 days)
Banquet: $14 in advance, $16 at door.
Flea Market Space: $15 in advance. (Valid for both days)

Make checks payable to Dayton HAMVENTION, Box 2205, Dayton, OH 45401.

Bring your family and enjoy a great weekend in Dayton. Sponsored by the Dayton Amateur Radio Association, Inc.

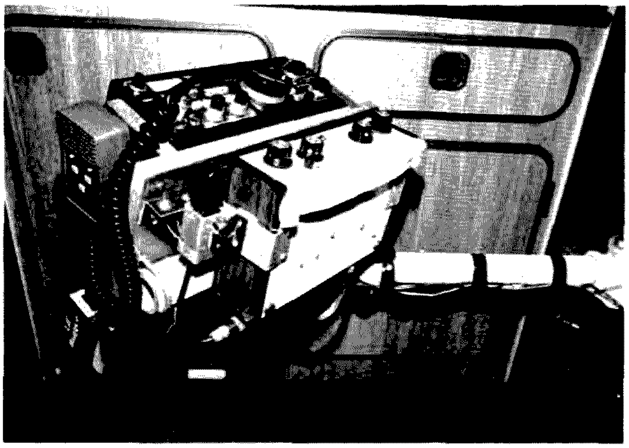
The Best Way to Mount Your Mobile Rig

If you have a van and HF gear, this is what you need to put them together—including a movable mount.

My wife and I walked out of the car dealer's office after deciding to buy a new camper van. "It will be great," I thought, "to be able to throw kids, dogs, and gear into the van and go." Just then an awful second thought occurred. "I wonder if the HF rig will fit in there?" I ran back into the showroom to eyeball the situation. "Hmm—the two-meter rig will fit to the left of the steering column, but no way am I going to get the HF rig under the dash."

Has this happened to you? Do you have a utility van or four-wheel-drive vehicle with no good place to put a rig? How about a camper or RV where you would like the rig in the front seat for traveling but in the back when stopped or during emergency or public-service operation?

That was the situation I faced—nowhere under the dash to put a rig without major alterations, and a desire to have a more convenient operating position when stopped for the night and a means to tuck the rig out of the way when it was not being used. This article will describe how I installed a rig in a 1980 VW camper. I designed a swinging gimbal mount, easily constructed from pipe and fittings available at most hardware stores, which could be adapted for use in vans and RVs with a central passageway between the two front seats.



Gimbal mobile mount.

Some Basics

First, let's take a look at some good mobile-installation techniques because one should begin by thinking carefully about the installation of mobile radios in modern vehicles and follow some basic principles. Attention should be paid to the 12-V-dc supply, transient protection, the antenna installation and ground system, noise suppression, and theft protection.

The 12-V-dc power should come directly from the battery. Depending on the length of the run and the amount of current, a wire size in the range of 8-12 gauge should be used. (Refer to the *ARRL Handbook* for information on the current-carrying capacity of various wire sizes.) A direct battery connection reduces the chance of high-voltage transients which can easily damage solid-state equipment.

The most damaging transients in an automobile are produced when starting and stopping the engine. Part of the checklist for pilots of light aircraft is to make sure the radio equipment is turned on *after* the engine is started and off *before* it is shut down. This simple procedure can be followed to protect your mobile radio installation. Further transient protection may be obtained by installing transient-suppressive devices in the power-supply leads at the radio. Techniques described by recent articles in *73* and *QST* show how to use devices now available. (See the list of references at the end of this article for more information.)

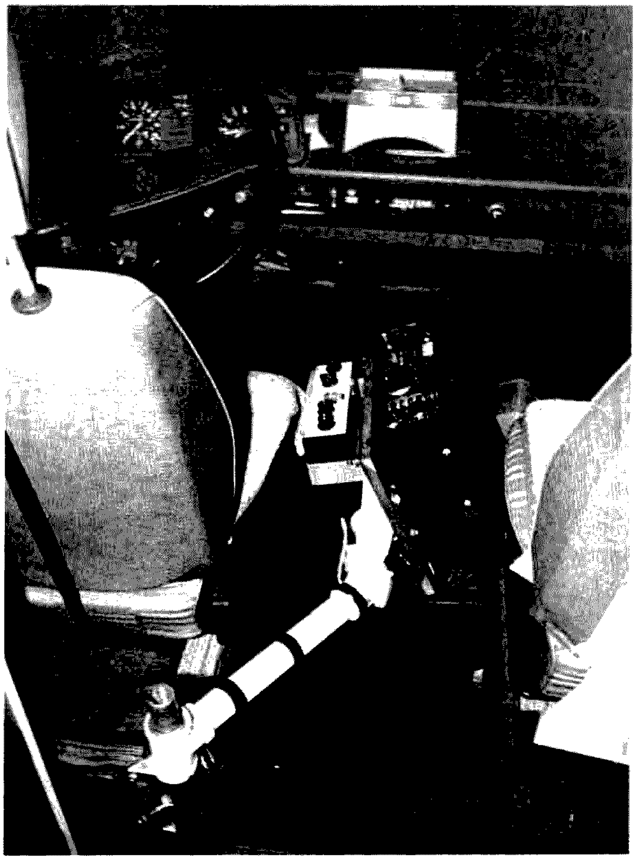
After the supply of a transient-free 12-V power source, the antenna is the most important aspect of a mobile installation. When the antenna is mounted on the rear of a van or station wagon, the rear door or tailgate can sometimes be in the way, so I have adopted an unconventional antenna mount. Good results have been obtained with two van mobile installations by mounting the antenna on the front of the vehicle. It works just as well, allows a much shorter coax run, and one can see the antenna in the front and watch out for overhead obstructions more easily. It also places the antenna away from the electrically-noisy engine compartment on the rear-engined VW van. The mounting bolt on the front bumper was removed and a longer one used to mount the antenna base. This directly connected the antenna to the chassis of the vehicle and provided a good ground for the antenna system.

A good grounding system is essential in a mobile installation. Many of today's cars have plastic parts in the dash and you must make sure that the rig is securely bonded to the chassis with as short a ground strap as possible. The antenna must be grounded to the frame as well. This can sometimes be difficult. One mobile operator I worked had taken the view that it was so difficult to get a good ground in the mobile installation that he isolated the base of the antenna from the automobile chassis and installed a ground plane by winding wire back and forth under the vehicle. His potent signal on 20 meters verified that this is also a good approach.

Antenna matching also is important. In the old days when rigs with tube finals were used, the swr on the antenna was of little consequence as long as the final would dip into resonance. In fact, best results were obtained by tuning the antenna with a field-strength meter for maximum signal output regardless of the swr indication. With today's solid-state transceiver, however, the swr protection circuits shut down the power output when the swr is greater than about 1.5:1. This means that an antenna tuner is required in most cases, especially if operation is required over any appreciable bandwidth. There are a number of small antenna tuners available today which are very suitable for mobile operation.

Noise can often be heard in a mobile installation. Noise sources fall into four categories—ignition or spark-plug noise, alternator or charging-system noise, instrument noise, and body noise. The 1982 *ARRL Handbook* gives good information on reducing spark-plug, charging-system, and instrument noise. Body noise is caused by various parts of the body not being electrically bonded to the chassis. Differential static charge can build up on these parts and cause severe noise when discharges occur. The solution is to bond the bumpers, trunk lid, and hood to the body electrically with grounding straps. I've found that noise is not a big problem when a good ground system is installed and a transceiver with a noise blanker is used.

Theft protection is best achieved by not advertising the presence of the rig. Quick-disconnect antenna mounts allow the HF antenna to be removed when you are not operating mobile. The swinging gimbal mount described below allows the mobile radio to be shifted around behind the driver's seat to be out of normal view from the outside. It also is designed so that the rig can be removed from the van easily when I am not operating mobile. (In case the worst happens, make sure your gear is fully insured.)



Gimbal mobile mount in operating position.

The Swinging, Gimbaled, Mobile Mount

The main design requirements for the mobile mount in my van were that it could not be under the dash (no room), it had to be movable so that it would not block the center aisle when it was not in use, and the rig had to be easily removable so that I could use it as my base station. These objectives were met with the design described here. In addition, the radio now is accessible from the back when somebody else is driving or while we are stopped for the night.

The photos show the mobile mount. The 12-V-dc power supply is directly connected to the battery, which is conveniently located behind the passenger seat. The radio-mounting bracket is constructed from wood but could be folded from sheet metal. (One also could use the manufacturer's bracket mounted on a piece of wood or sheet metal.) The mount is attached to the top bar of the swinging gimbal with U-bolts. As shown in the photos, the antenna transmatch is mounted under the transceiver. A paddle and small keyer are on the side of the mount and are within easy reach of the driver when in mobile operation.

Fig. 1 shows the design of the swinging-gimbal portion of the mount. It is constructed from two pieces of 1¼-inch pipe, one pipe tee, one regular elbow, and one street elbow. The maximum length of "A" is determined by measuring the distance from the fixed-mounting point to the nearest obstruction which the mount must clear. Subtract 3.5 inches to allow for the tee and elbow connections to be made. The minimum length of "A" is the same as the width of the transceiver-mounting bracket plus about an inch.

Thread this pipe and securely screw the tee and regular elbow onto the ends. The tee and elbow are tapped for 1/4-20 machine screws as shown in Fig. 1. These serve as tension adjusters to keep the mount from swinging too freely. Make the length of "B" the same as "A" but thread only

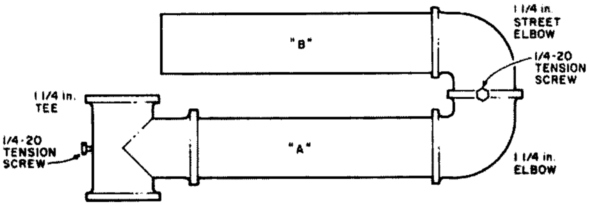


Fig. 1. Gimbal-mount construction detail.

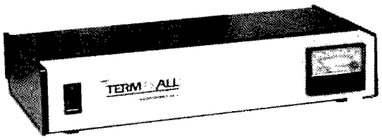
TERMINALL

RADIO MODEM



apple* TRS-80* ATARI*

SEND & RECEIVE CW & RTTY

TERMINALL is a hardware and software system which converts your Personal Computer into a state of the art communications terminal.

- TERMINALL is easy to use. Plug into your receiver headphone jack and copy Morse code or radioteletype. Plug into your CW key jack and send Morse code. Attach a Microphone connector and send Baudot or ASCII RTTY using audio tones (AFSK). That's all there is to hooking it up.
- Fantastic Morse reception. No adjustments are necessary to receive Morse code. It's fully automatic! Six stage active filter demodulator and auto adaptive Morse algorithm copies the weak and sloppy ones.
- Separate RTTY and CW demodulators. Built in crystal controlled AFSK. CW and PTT keying. 60 mil loop intercomnect. RS 232 IN and OUT. hand key input and side tone output.
- Built in parallel printer driver software allows hardcopy in all modes.
- Hardware clock maintains accurate time.
- Multiple user defined WRU functions. You select initiate sequence, terminate sequence, what to transmit back and whether to save on tape or disk.
- Word wrapping, word mode editing, diddle, ignore carriage returns, user programmable end of line sequence, adjustable carriage width, transmit delay (fixed, none or auto adaptive), excellent documentation, break mode and much more.
- TERMINALL has capabilities far surpassing dedicated terminal systems. And since it works on a general purpose computer, the majority of your investment (your computer)is spread out over many different applications. **You get more for your money.**
- Complete with software on cassette and diskette, assembled and tested hardware, and extensive instruction manual. Call or write for specifications on TERMINALL for TRS-80 Model I or Model III, Apple or ATARI 400/800 COMPUTERS. **$499.**
- 15 day money back trial period. One year parts and labor limited warranty on factory direct orders.

one end and securely screw the street elbow onto it. You are now ready to install the mount in the vehicle.

I had a table mount in back of the driver's seat onto which I slipped the tee joint and tightened the tension screw. You may have to provide a vertical pipe screwed into a pipe flange mounted on the floor of your vehicle. If this is the case, replace the tee in Fig. 1 with an elbow. Screw the street elbow on the end of pipe "B" into the regular elbow on pipe "A" and tighten the tension screw so that the arm will swing from the storage position to the operating position. Use U-bolts to attach the transceiver mount to "B." Dress all power-supply leads, grounds, coax, and speaker leads along the pipe with the mount extended, and tape securely.

Conclusion

It is very easy to start mobile operation with today's solid-state rigs. A little care with the installation can result in many hours of happy mobiling. By providing a transient-free environment one also is able to protect the transceiver from destructive voltage spikes. A good grounding system is the key to an effective antenna installation and also will help reduce noise. A swinging, gimbaled, mobile mount as described above can be adapted for use in many vehicles where there is not enough room to mount a rig under the dash. ■

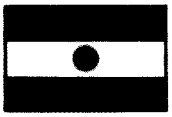
73 INTERNATIONAL

Beginning this month, 73 brings you amateur radio news from around the world. In this collection of reports from our foreign correspondents, 73 will present the latest news in DX, contests, and events, as well as keep you abreast of the technical achievements of hams in other countries.

If you would like to contribute to your country's column, write to the country editor or to 73: Amateur Radio's Technical Journal, *Pine Street, Peterborough NH 03458, USA, Attn: Avery L. Jenkins WB8JLG.*



INDIA

Amar N. Banerjee VU2CZ
PO Box 3005
New Delhi-3
India

The Government of India has permitted each Indian ham to obtain foreign exchange to the tune of about 1,000 dollars every year to import amateur equipment, parts, and instruments. It is not necessary to obtain an import license; hams can just go to the bank and obtain a draft or open letter of credit on the basis of a pro forma invoice. Customs duty is about 68 percent for transceivers and more than that for other items.

Three Indian amateurs distribute equipment made by Yaesu, Icom and Kenwood. During the middle of 1982, Yaesu offered a "slashed price" for their equipment and "rock-bottom concessions" for the VHF hand-held FT-207R. As a result, there is a sudden growth of VHF activity in India, and about 80 of the FT-207R rigs are expected to arrive by the end of 1983. Fifteen FT-207Rs were used to maintain a communication link between the stadiums of the 9th Asian Games at New Delhi and Jaipur.

The IBP Indian beacon is now operational around the clock at New Delhi. Its callsign is VU2BCN, and it is on FM at 28.295 MHz.

The decades-old 10-kHz slice in the 80-meter band has been expanded to 50 kHz. VU amateurs now operate from 3500-3540 kHz and from 3890-3900 kHz.

The total number of valid amateur licenses was expected to pass 1,100 by January, 1983.

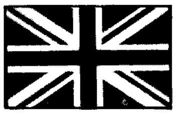
The new WARC bands have not yet been opened for use in India.

Air-Net India assembles every day on 14.150 MHz at 1530 UT. There also are daily nets on 7 MHz and 3.5 MHz.

Commemorative callsigns, past and present:

- October, 1969—prefix VU0 rather than VU2 to mark the Gandhi Centenary Celebrations. The Amateur Radio Society of India issued a Worked Republic of India (Gandhi Centenary) Award.
- August-December, 1972—Callsign VU25 instead of VU2 marked the 25th anniversary of Indian independence.
- May, 1979—VU25ARS marked the 25th anniversary of the Amateur Radio Society of India.
- November, 1981—AU2CD was issued to mark the annual children's day celebrations, which begin every year on the birthday of the late Jawaharlal Nehru, the first Prime Minister of India.
- December, 1981—AU2SIF was issued to the station at the South Indian Fair at Hyderabad.
- August to December 15, 1982—Callsign prefix VU9 instead of VU2 to mark the 9th Asian Games being held in India at New Delhi, Bombay, and Jaipur.
- November 14, 1982 to December 4, 1982—Callsign VU82AG was issued to VU2CJ/VU2ARD to begin on the annual children's day celebrations at the site of the celebration. This callsign was to continue until the end of the 1982 Asian Games.
- November 24, 1982 to December 4, 1982—Callsign AU9ASG was issued to VU2APR (Hyderabad APARS) representing the 9th Asian Games. A group of amateurs from South India, Hyderabad, maintained HF communications between Jawaharlal Nehru stadium, New Delhi and the Asian Games stadium at Jaipur.

A cyclone hit the western India coastal area in November of 1982. Civil communications links were disrupted, and three radio amateurs from APARS Hyderabad (South India) rushed in and rapidly established communications on HF along with radio amateurs of Gujurat. Successful two-way communications around the clock were provided from eight affected stations for the district authorities who were conducting relief operations. This is the second major participation of amateurs in India since the disaster of the Morvi floods in the same state a few years ago.



HONG KONG

John H. Holstead VS6HJ

91 Leighton Road
Hong Kong

The Hong Kong Amateur Radio Transmitting Society, better known as HARTS, has been in existence and actively engaged in amateur radio in this Pearl of the Orient, the British Crown Colony, since pre-WWII days.

At present, there are approximately 150 licensed members. HARTS is affiliated with the Radio Society of Great Britain. It also is a member of the International Amateur Radio Union. The membership is extremely unusual in that it is composed of many nationalities, e.g., Chinese, British, German, Canadian, American, Australian, and others.

Just last year and for the first time, a Visitor License was introduced, and approximately a dozen amateurs from other countries received this unique license. It is issued to the holders of amateur licenses with whom the United Kingdom has reciprocal agreements, and is issued to those persons who will not be residents for more than 90 days. The only requirements are to have the original license (with photocopy for Post Office file) and passport, and upon payment of $100.00 HK ($16.00 US), permission to operate using the home call /VS6 will be granted. This license is valid for one year. For further information, one should write directly to: Telecommunications Division (Maritime Services), G. P. O., 2 Connaught Place, Hong Kong.

Remember that HARTS does have a warm HEART! If any amateur radio friends pass through this crossroad of South East Asia, they are invited for an "eye ball" at the regular Tuesday meeting, 1700 local (excluding public holidays) at the Cable and Wireless Sports Club, Caroline Hill Road (Hong Kong Island side). For additional information concerning HARTS, please write to its president, Bob Frost VS6BQ, HARTS, PO Box 541, Hong Kong.

HONG KONG AWARDS

CATCH 22 AWARD. Applicant must submit verified evidence of two-way contact with other amateur stations located on the 22nd parallel of latitude north (see list). A Hong Kong station contact is obligatory.

Only contacts after 1st January 1980, are valid. Endorsements for mode and band may be requested.

The award is available in three classes: Class 3—contacts with at least 15 countries; Class 2—contacts with at least 20 countries, and Class 1—contacts with all 25 countries.

Fee US$7.00 or equivalent currency.

All awards will be returned by airmail, and upgrade stickers may be applied for with a fee of US$1.00.

Countries list:

1.	VS6	Hong Kong
2.	CR9	Macao
3.	BY	China
4.	BV	Taiwan
5.	XV	Vietnam
6.	XW	Laos
7.	XZ	Burma
8.	S2	Bangladesh
9.	VU2	India
10.	A4X	Oman
11.	A6X	U.A.E.
12.	HZ	Saudi Arabia
13.	ST	Sudan
14.	SU	Egypt
15.	5A	Libya
16.	TT8	Chad
17.	5UT	Niger
18.	7X	Algeria
19.	TZ	Mali
20.	5T5	Mauritania
21.	CN	Morocco
22.	C6	Bahamas
23.	CO	Cuba
24.	XE	Mexico
25.	KH6	Hawaii

NINE DRAGONS AWARD. One contact with a country in each of the following 9 zones: zones 18, 19, and 24 to 30 inclusive. Contact for zone 24 must be a VS6. Stations within the 9 zones require 2 contacts in each zone, with 2 VS6 contacts. Only contacts after 1st January 1979 are valid. Fee is US$3.00 or 25 IRCs.

FIRECRACKER AWARD. Six contacts with different VS6 stations. Stations in zones 18, 19, 24 to 28 require 10 contacts with different VS6 stations. Only contacts after 1st January 1964 are valid. Fee is US$2.00 or 10 IRCs.

The usual conditions apply to these awards: Send certified log extracts only; no QSL cards are required. Payment to be made in cash or checks payable to HARTS. If sending postal orders please leave payee blank. Claims to Awards Manager, HARTS, G.P.O. Box 541, Hong Kong.

HONG KONG—ACORNS TO OAK TREES

A couple of years ago, the International DX Foundation ran an expedition to several different countries in the Far East which ended up in Macau where, after completion, the team left for the United States and left the amateur radio gear in Macau to be used by subsequent visiting amateurs. The equipment was in fact used twice and then returned to me (VS6CT) in Hong Kong for return to America. However, by the time freight costs were taken into consideration, it was felt that it would be better to sell or donate the gear to worthwhile persons. A Yaesu 901 was sold, a Denton linear was donated to 9M8PW, and the other transceiver—a Yaesu FT-101ZD—was donated to the Boy Scouts Association of Hong Kong.

As a direct result of this donation, one of our regular licensed amateurs, Kenny Chan VS6CN took on the task of organizing a radio club within the Scouting movement here in Hong Kong and commenced training classes for 20 interested Scouts. Happily, they all sat for the City and Guilds of London, Radio Amateur Examination, held at the beginning of December and we eagerly await the results, due early in 1983. Possibly by the time you read this, VS6EA, the Boy Scouts Club station, will be on the air operated by new licensees whose introduction to amateur radio was brought about solely because of the International DX Foundations donation of gear.

Another tale in a similar vein was that of the committee of the Hong Kong Amateur Radio Society (and myself as President) getting the Hong Kong Post Office to extend the no-code VHF license currently available in the United Kingdom to Hong Kong. The first committee session with the Post Office was set up early in 1981, and after much discussion the first VS6X license was issued in the spring of 1982. To date, we have 55 no-code VHF licenses issued, opening a new era in amateur radio activity in Hong Kong. The most interesting aspect was in persuading the local Post Office not to follow the UK regulations too tightly and allow local use of 50 MHZ in keeping with ITU recommendations that no-code licenses be permitted to operate above 30 MHZ.

The enthusiasms of this new group of amateurs is refreshing; the first weekend in December, on their own initiative, they attempted 2-meter DX to Japan from Hong Kong, spending 36 hours under canvas on a high hilltop above Kowloon with a 40-element array on 2. Japan was heard, but the reverse, this time, was not, so all that could be credited was a cross-band contact; but it's a great start for a totally new group of amateurs and we are hoping for greater things to come.

AMATEUR RADIO IN HONG KONG

As Hong Kong is linked with the United Kingdom in all matters relating to international affairs, it follows that we adhere to those conditions of licensing applicable in the United Kingdom, except where region three varies in frequency allocation, i.e., we use 50 MHz, which is not allocated in the UK.

There currently are two classes only of amateur license issued in Hong Kong, the full license for all bands, all modes and the restricted license, telephony mode with frequencies in the 50, 144, and 430 MHz bands.

The requirements for a class A license issued to a newcomer to amateur radio in Hong Kong are that he should be over 16 years of age, a British subject, have passed the City and Guilds Radio Amateur Examination, be proficient in the Morse code,

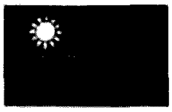
tested to 12 wpm, and have paid a HK$100 annual license fee.

For a class B license (restricted, telephony only) there is no requirement for the Morse-code proficiency test.

The above licenses are issued to persons who will be resident more than three months in Hong Kong. In the event that a person takes up residence and has an overseas license, he will be granted a full VS6 license of the class which he holds, i.e., a full or restricted license.

Currently, the conditions of the existing license are being reviewed as it contains no permission to operate mobile, although oral agreement has been given and we have considerable activity on two meters, where we have two repeaters—VS6HK, 145.650-150 and VS6KP, 145.750-150.

For propagation purposes we also are operating two beacons, both located at Mt. Kellet on Hong Kong Island at an elevation of 500 meters—VS6TEN on 28290 and VS6SIX on 50.075.



TAIWAN

Tim Chen BV2A/BV2B
PO Box 30-547
Taipei, Taiwan
Republic of China

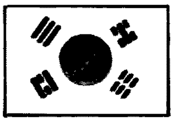
Sherry and Wayne W2NSD were here to participate in an electronic show sponsored by Taiwan manufacturers. The Greens had been to Taipei at least three times in years past, and were pleased to see the changes and development of Chinese electronic products. The exhibition takes place annually and attracts visitors and buyers from all directions. In the show this year we saw that computer science is quite popular and fascinating.

During October and November I had 25 hams or radio fans visiting my station BV2A/BV2B (the only licensed station in Taiwan). In November, I won the first place trophy of the International Lions Club Radio Contest on CW. This led to considerable publicity which I was able to use to promote the interests of hams and amateur radio. For example, the Taiwan Broadcasting Corporation and its substations across the territory have widely commended the great interest in ham activities and urged local authorities to grant more station licenses without delay.

Director chairman David Rankin 9V1RH/-VK3QV was traveling on his way to Singapore from Tokyo and stopped over at Taipei last October. Accompanying me, David was to exchange information on world amateur radio with a VIP of the Post and Telecommunications Department. His impression is that Taiwan is a free and open society with a booming economy and many progressive youths keeping abreast of the state of the art in sciences. He felt that there should be many more ham stations on the air. However, the China Radio Association and Amateur Radio Commission are working closely on this matter.

Please note the following:

- For BV2A, QSL manager is Charlie Moraller K2CM in the States.
- For BV2B, QSL direct to PO Box 30-547, Taipei, R.O.C. (Box 101 will not be used after February, 1983).
- On Wednesday, 1130-1400Z BV2A CW 21030/21100 or 14025/14040, and SSB 21270/21350 occasionally. Also, 1400-1600Z BV2B SSB 14218/14250±.
- On Saturday, 2300-2400Z BV2A CW 14025/14040 or BV2B SSB 14218/14250.
- On Sunday, 0000-0200Z BV2A CW 21030/28030 or BV2A SSB 21350/28530.



KOREA

J. Michael Wengert HL9KT/KH2AC
CPO Box 2961
Seoul, Korea

Amateur Radio in Korea is on the upswing with the announcement last year that Seoul would be host to the Asian Games in 1986 and the Olympics in 1988. Until that time, little notice was given to the public relations aspect of ham radio by the Korean government or by the average citizen. With the active efforts of KARL (the Korean Amateur Radio League) and AARCK (American Amateur Radio Club of Korea), ham radio has almost become a household word. In the past year, many newspaper and broadcast accounts of the public service aspects of the hobby have reached the public, and the government is beginning to ease its stringent control of the import of transmitting equipment and also is allowing new modes of operation.

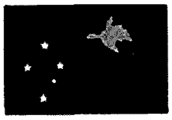
In Korea, operation is permitted by Korean nationals who pass a written exam and, in some cases, a CW test. The most popular license is the 3rd class radiotelephone license. This is obtained by passing a comprehensive theory, regulation, and operational examination administered twice a year by the Ministry of Communications (MOC). There is no code exam for this class license and the written exam is roughly equivalent to the US General Class FCC exam. Privileges for this class are phone operation only in the 80, 40, 15, 10, 6 and 2m bands. The 3rd class radiotelegraph exam is the same as for radiotelephone but includes a CW test and allows CW operation on the same group of frequencies. The power limit in both cases is 50 Watts output.

A more difficult exam, including a section on English ability and a faster code test, brings a Korean ham the 2nd Class License with 100 Watts and additional operation on 20 meters. A small number of Korean hams have the coveted 1st Class Ham License which permits transmitter output power up to 500 Watts and has an equivalently more difficult examination. If an aspiring Korean ham successfully gets his operator's license, he may operate a club station and/or apply for his own station license.

At this writing, although the licensed operators number more than 7,000, fewer than 700 club and private station licenses have been issued. There are several reasons for this, the most important being the difficulty in getting suitable transmitting equipment. Additionally, the issuance of a station license (and hence a callsign), is extremely difficult. Due to the security problems of a divided Korea, the north being a hostile state, a close background check is conducted on all individuals applying for a station license. When the background check is cleared, then permission to construct a station is forthcoming.

If an individual is successful in obtaining some transmitting gear and puts up his antenna system he will then be issued a callsign. But his actual permission to operate is not issued until inspectors from the MOC have visited the ham's shack and confirmed that the station complies with current regulations as specified by the ham's class of license. Only then may the new ham go on the air and begin to really enjoy the international hobby to its fullest extent.

Even if the new ham submits his application for station license immediately, it takes upwards of 6 months to get on the air. For the benefit of newcomers with no knowledge of amateur radio regulations, operation, or theory, KARL conducts three-week cram classes several times a year. What about those HL9 stations you hear with American accents? We'll cover amateur radio licensing for foreigners in next month's column. 73 from the Land of the Morning Calm.



PAPUA NEW GUINEA

Siegi Freymadl P29NSF
PO Box 165
Rabaul, Papua New Guinea

In a country of inaccessible terrain such as Papua New Guinea has to offer, communications are of vital importance. As far as telecommunications are concerned, this country has one of the most modern microwave systems with some of the transmitters powered by solar energy. We can dial STD and ISD. This is a country of paradoxes, where Stone-Age and modern technology coexist.

The radio amateur is privileged in PNG, as generally he is not restricted as to number or height of antennas and has less QRM to contend with. This is particularly so in my case. I live on New Britain Island 80 km from Rabaul, on a cocoa/copra plantation. We have no neighbours for 5 km on either side, no television, and no local council to object to the "antenna farm"—an amateur's paradise.

To become an amateur, one has to sit for exams identical to those given to candidates in VK, on the same days, and at the same time as in Australia. For the CW exam, one now has to make the trip to Port Moresby where the radio inspector will give the test (700-km crow-flight miles, but *many* more by sea from Rabaul). That is one reason why I now will have to remain a Novice! Traveling that far is out of the question.

When I sat for the Morse exam a little over three years ago, the radio inspector came to various centers to hold the tests, but, of course, it proved to be too costly an exercise for the department. Then, the theory and regulations papers were mailed and kept in the care of the local postmaster until the day and hour of the exams. One then completed them under his watchful eye.

Amateur licenses are issued by the Radio Branch of the Posts and Telecommunications Corporation in Port Moresby and the licensing fee is K6.00 per annum (about $7.50). The Papua New Guinea Amateur Radio Society is the official body representing amateurs in PNG, and Peter P29PS is the interim president. The address of the PNGARS is PO Box 204, Port Moresby; the address of the QSL Bureau is PO Box 141, Port Moresby. There now is a North Solomons Radio Society for amateurs on Bougainville Island, but at this time I have no further details.

There are around 120 amateurs in PNG, of whom one is a national: Sidney Kulupi P29SK, who is the manager of the Radio Branch.

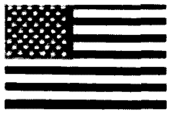
There are two repeaters: P29RPM Port Moresby 146.40/147.00 and P29RAE Mount Albert Edward 146.05/146.65. A repeater is in the process of being built at Bougainville which we hope will link up with Mt. Albert Edward.

The PNGARS has a society net every Thursday on 3565 KHz ± QRM, at 0930 GMT. The Society also publishes a newsletter, *Garamut* (a garamut is a native drum), which appears sporadically. One of the biggest problems probably is that the amateurs are scattered over such a vast area. For instance, on my 600+ km long island there are only two other amateurs, both in Rabaul: Andy P29SA and Syd P29SS.

The PNGARS sponsors the very attractive Bird of Paradise Award. Requirements are seven contacts (all bands permitted, all modes) with amateurs in five different provinces. (There are 19 provinces in Papua New Guinea, although there are not amateurs in every province.) The awards manager is Col Button P29NAB, PO Box 2450, Konedobu, National Capital District, Papua New Guinea; the fee is K2.00 or 10 IRCs. It is a good idea to ask for details of the province, when making contact with a P29 amateur. The Bird of Paradise Award is a beautiful one and certainly an adornment to any shack, but Col reports very few applications of late; so how about it?

At the moment, conditions are very poor on 15 and 10, but I am very active and doing my best to put P29 on the map. Of course, 20m is off limits, as I am only a Novice.

That's all for today. I'll see you next month with more news. Best 73!



GUAM

J. T. Pogue KH2AR
68 Banyan Circle
FPO San Francisco CA 96630

We have a popular T-shirt here that reads WHEREINTHEHELLISGUAM? That's a fair question, and the answer to it seems like a good way to begin this column about our island.

For you geographers, Guam is located at 13°28' north and 144°45' east. For the rest of us, that translates as roughly 3600 miles west of Honolulu, 1500 miles east of Manila, 1500 miles south of Tokyo, and 6000 miles west of Los Angeles. It is the largest island connected with the US government between Hawaii and the Philippines, as well as the most populated. Indigenous residents (composed mostly of native-born Guamanians and people of Filipino, Japanese, Chinese, and Korean ancestry) number approximately 85,000. There are also another 20,000 people connected with the US armed forces and US government.

Guam is often known in this part of the world as the "Caribbean of Japan." With more than 75% of the annual 300,000 tourists coming from there, the title seems to fit.

From 1521 when Magellan stumbled upon the island until 1898, Guam was part of the Spanish Colonial Empire. Administered first from Mexico, then later from the Philippines, Guam was an important link in the flourishing galleon trade between east and west. As a result of the Spanish-American War, Guam came under the mandate of the US government. With the exception of a period of Japanese occupation during WW II, the island has progressed steadily toward modernization, Americanization, and self government.

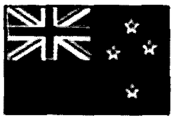
The island's present status is that of an unincorporated territory. However, there now is a newly-kindled interest in changing this status to full commonwealth. The people here remain some of the most loyal and patriotic citizens under the US flag.

Ham radio got an early start on Guam. With the presence of many US servicemen and civilians in the early part of the century, it proved to be a great source of recreation as well as a convenient way to stay in touch with the rest of the world. The FCC didn't seem to show much interest in callsigns prior to WW II, so the fellows who operated from here invented their own prefix. The OM prefix (which stood for Oceania-Marianas) may be familiar to some old-timers.

After the war, the FCC got its act together and established the KG6 prefix with the additional allocation of KG6R, KG6S and KG6T for the newly acquired trust-territory islands of Rota, Saipan, and Tinian respectively. Later, in their sometimes confusing "wisdom," the feds once again changed these prefixes to KH2 for Guam and KHØ for the Northern Marianas.

At present, there are approximately 100 hams on Guam, with roughly 60% of them active on HF. The ham population is about 75% military and 25% civilian. With frequent transfers for the military people, the ham population receives a constant infusion of new operators anxious to add the KG6 or KH2 prefix to logs around the world.

Until next time, Hafa Adai from Guam.



NEW ZEALAND

D. J. (Des) Chapman ZL2VR
459 Kennedy Road
Napier
New Zealand

The amateur radio scene in New Zealand as observed through the latest available IARU statistics informs us that there are 5631 licensed operators here, 2898 (51%) being members of the New Zealand Association of Radio Transmitters (NZART), the New Zealand equivalent of the ARRL. Our current net annual increase in licensed amateur operators is about 6%, or around 300 each year. Amateur radio operator examinations are held twice each year, in March and September, and they attract about 500 candidates; the pass rate is approximately 50%.

A growth comparison with the United States from the same IARU statistics available here in New Zealand indicates the present US net growth rate is a little over 1%, so, even though there are many more amateur radio operators in the USA, the growth rate here is approximately six times the US growth rate for our hobby. Therefore, even though we are a small country (population about 3.5 million) amateur radio is very much alive and on the increase in popularity here, "down under."

Our regulatory body is the New Zealand Post Office, a government agency. (The Post Office in New Zealand operates, controls, and constructs the telephone, telegraph, telex, and radio-telephone communications network services, savings bank services, collection and distribution work on behalf of other government departments and agencies, as well as the postal and mail-handling services.) The amateur service is controlled and regulated by Radio Inspectors of the Post Office, who also control and regulate all radio broadcasting and communications services, commercial and private. There is an annual license fee of about US$10.00 for an amateur radio operator's license, and our maximum allowable power input is 150 Watts.

The ZL scene covers most aspects of our hobby—ATV, slow scan, RTTY, VHF, UHF, SHF, EME, AMSAT, and, of course, CW, SSB, and a little old-fashioned AM.

In future columns I shall discuss in depth the activities in these and other specialized aspects of our hobby practiced here on the New Zealand scene. Also from time to time I will cover awards within ZL, DXpeditions within our area, contests, and other subjects considered to be of interest to amateur radio readers of *73*.

BITS 'N PIECES

For prospective visitors to ZLand, a reciprocal license is easily obtainable from the Radio Inspectors Branch of the Post Office, provided the amateur's country of origin has reciprocal rights with ZL; I shall supply the necessary information on this subject in another issue.

There is a fairly extensive 2m VHF repeater network covering the two main islands, and also some 70cm UHF repeaters in the four main centers and in one or two other areas. So, for the visitor, a 2m hand-held opens up the ham scene through any of the 45 repeaters in the system as you travel throughout our country. If the overseas amateur operator is fortunate to be visiting a locality when the local Radio Club monthly meeting night is scheduled, a warm welcome awaits the visiting ham, and he/she is usually escorted to the meeting venue by one of the local members. Over the past 12 months my local club, in a town of just under 50,000, has been host to visitors from Canada, the United States, Australia, and South Africa at our monthly meetings—and it is only one of the 80 branches (clubs) of the NZART scattered throughout New Zealand!

COMING ZL HAPPENINGS

World Communications Year, 1983—New Zealand Activity Day, 0000 GMT to 2400 GMT, May 21—the Council of NZART has designated this 24-hour period as our main activity for WCY. ZL operators will be active on all bands and modes for the 24-hour period to ensure that New Zealand does its bit toward WCY. Special callsigns will be used for WCY Activity Day—ZLland has been divided into 8 regions, and each regional coordinator has been allotted a WCY callsign for use by the stations operating in their areas, demonstrating ham radio to the public.

Look for ZLs 1 to 4 and 6 to 9 WCYs during the 24-hour period on all bands and all modes; see if you can work all 8 regions on the special activity day.

Commemorative QSL cards will be sent to all stations contacted by New Zealand WCY Activity Day/stations via the QSL Bureau system. However, if your station does not participate in the system, the operator *must request direct QSL at the time of the QSO*, and send an SAE plus 3 IRCs with details of the QSO, to the ZL WCY station worked, c/o NZART QSL Bureau, PO Box 40-212, Upper Hutt, New Zealand. It is not necessary to send your QSL card—our Commemorative QSL card will be sent automatically via the QSL Bureau unless otherwise arranged during the QSO.

NZART Annual Conference and Convention—Friday, June 3, 1983, to Monday, June 6, 1983, at Dunedin in the South Island, ZL4 land. Overseas visitors very welcome. Enquiries to PO Box 6050, Dunedin, New Zealand.

Should there be any questions from *73* readers about the ZL amateur radio scene, or on topics discussed in this column, write to me at my ZL address, but please include 2 IRCs for an airmail reply. All letters will be answered, provided the return postage is included as requested.

CHILE

Patricio Fernandes H. CE3GN
PO Box 14781
Santiago de Chile

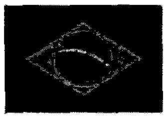
The Radio Club de Chile was founded by a small group of visionary radio experimenters on July 12, 1922, and has just celebrated its 60th year since that date of historical significance for all Chilean hams. The Chilean Society has grown to be one of the most active radio organizations in all of South America.

The club, a member of the IARU since its founding, owns a comfortable two-story building with a variety of facilities for the club's 2,200 members. There is a conference hall which can hold over 500 people and three radio shacks with modern equipment for all modes. The building also contains several classrooms for students attending the various courses given throughout the year which prepare them for the final examinations before getting their Novice and General tickets.

The Import Department provides members with up-to-date equipment from different manufacturers all over the world. The club even has a stock of a variety of gear which is sold to members at convenient prices. Another office, the VHF Department, is in charge of the various 2-meter repeaters belonging to the club, which are located at very high spots around Santiago. The QSL bureau service is also very active, handling over 150,000 cards per year.

The events commemorating the 60th anniversary showed that the club holds an important place in Chilean affairs. There was a Chilean commemorative stamp issued on December 29, 1982, and a big meeting at one of the auditoriums of the Diego Portales Building in downtown Santiago. Over 400 members and important government authorities were present, including Colonel Jaime Machuca, Subsecretary of Telecommunications. The Colonel was representing the President of Chile, General Augusto Pinchet Ugarte XQ3GP. Also present were Carlos Kaufman, president of Radio Club Argentino, representing both the IARU and the ARRL, and Sr. Enrique Sazie, one of the founders of the Radio Club de Chile. A plaque and gold medal were presented to him in recognition of his extensive work on behalf of amateur radio.

Also, a private lunch was held at CE3JK's QTH in honor of Carlos Kaufman, and in the evening there was a meal served for over 250 people at a private club in Santiago, at which Rogelio Gomez, president of the Radio Club de Chile, presided.



BRAZIL

Carlos Vianna Carneiro PY1CC
Rua Afonso Pena 49, Apt. 701
20270 Rio de Janeiro, RJ
Brazil

Gerson Rissin PY1APS/PY7APS
PO Box 13178, Copacabana
20000 Rio de Janeiro, RJ
Brazil

The Rio DX Party first sponsored last October by the Brazilian CW group, PPC (the Picapau Carioca—the Carioca Woodpeckers), with the cooperation of all other Brazilian CW groups, will be held again from 1500 UTC March 26 to 1500 UTC March 27. The main purpose is to promote two-way QSOs between Brazilian and DX stations, enabling both to FB QSL for awards and so on. No logs, no nothing except quick QSLing is essential. Exchange RST/Name/QTH, and try to get as many rare Brazilian prefixes as you can. There are 26 (or even 27 if you are lucky to get one of the rare Brazilian ocean islands PYØ prefixes).

For best fun, the best CW operators in Brazil will be invited by calls and letters to join in so that prefix-hunters can have a good day! Ever get a PU8 CW QSL? No? Neither have I! So, I'll meet you at the Party, with the PT8s, PR7s, PT9s, PS8s, PY9s, and, who knows, maybe even a PU8, too!

All HF bands, first 20 to 50 kHz, and also from 21130 to 21150 kHz, aiming at USA Novices.

Brazilian prefixes, in order, are:
PP1—Espirito Santo ES
PP2—Goias GO
PP5—Santa Catarina SC
PP6—Sergipe SE
PP7—Alagoas AL
PP8—Amazonas AM
PR7—Paraiba PB
PR8—Maranhao MA
PS7—Rio Grande do Norte
PS8—Piaui PI
PT2—Distrite Federal DF (Brasilia)
PT7—Ceara CE
PT8—Acre AC
PT9—Mato Grosso do Sul MS
PU8—Amapa AP
PV8—Roraima RR
PW8—Rondonia RO
PY1—Rio de Janeiro RJ
PY2—Sao Paulo SP
PY3—Rio Gran de do Sul RS
PY4—Minas Gerais MG
PY5—Parana PR
PY6—Bahia BA
PY7—Pernambuco PE
PY8—Para PA
PY9—Mato Grosso MT
PYØT—Trinidade Island
PYØF—Fernando de Noronha Is.
PYØS—Sao Pedro/S. Paulo Rocks

RECIPROCAL LICENSES IN BRAZIL

These are the countries Brazil has reciprocal licenses agreements with: Germany, Bolivia, Canada, Chile, Costa Rica, Great Britain, United States of America, Paraguay, Portugal, Dominican Republic, Sweden, Switzerland, Denmark, Venezuala, Colombia, and France.

OLD MISINTERPRETED CW

Just like everywhere else, in Brazil there are many yeses and many nos to CW! The same empty arguments, the same Bla-Bla-Bla (empty talk) we hear and read from all parts of this radio amateur world of ours! The only difference is: Here we are acting different! We work for CW instead of keeping talking and talking. Since 19 years ago, the PPC Group (the only CW group) has been helping, developing, and stimulating CW use among radio amateurs in Brazil. First there was a very simple 10-Member QSO Award; then a National CW Contest; then a second one (a QRS Contest for beginners); then Certificates—about 5 or 6—and a PPC Certificate Hunters Club; then new awards and certificates aiming at DX operations, jumping frontiers in all directions and considering two-way interests; and now, the Rio DX Party twice a year and supervision of the WWSA CW Contest (Worldwide South American Contest), sponsored by *Electronica Popular*, the only Brazilian radio amateur magazine, and in close supervision of GACW Argentina CW Group, wherefrom came the idea.

And how about results? You may ask! First, many many other CW groups were

born, all aiming exactly at the same ideals. New Brazilian hams are studying CW not just for examination purposes but because they love CW and because CW is now a very strong mode in Brazil.

Still suspicious, friends? Well, question the fabulous family of Brazilian CW groups: GPCW in Santos SP, CWSP in S. Paulo, GCWA in Araras SP, ABCW in SP, UBR in Recife, PACW in Para, CWSA in SP, CWRJ in Rio, PRCW in Curitiba, MCG in Rio Grande do Sul, Tabajara Tribe in Espirito Santo, Pantaneiro in Mato Gosso, CWDF in Brasilia, CWMG in Minas Gerais, and I *can't* finish because there's a new one born every moment!

RESULTS OF THE 1982 WORLDWIDE SOUTH AMERICA CW CONTEST

DX Winners

7 MHz—JH7BDS
14 MHz—OK2TBC, JH1IFS, JA1OHP
21 MHz—F6DKV, W4VQ, DL1BBO
28 MHz—EA7CJM
Multi-Band—DL8KJ, AI9J, N6MU

AWARDS

UBR AWARD. Sponsored by the CW group Uniao Besouros do Recife, the UBR Award is available to all licensed amateurs for confirmed contacts with UBR members. Contacts must have been made after September 1, 1975, on any amateur band. Only two-way CW mode. No QSL. Send GCR log of stations worked (call, date, time, band, mode, and report) and 10 IRCs to: Uniao Besouros do Recife, PO Box 1153, 50000 Recife, Pernambuco, Brazil.

There are no special endorsements for the UBR Award.

UBR Members:

PY7AEF	PY7CC/1	PP6AAC
PY7ADL	PY7DM	PP7IE
PY7AEV	PY7RO	PP7FAL
PY7AOR	PY7RX	PP7JCO
PY7AVZ	PY7ZZ	PR7AEN

PY7CCZ	PY3AVF	PT9EJ
PY7CW	PY5NR	

DCM AWARD. Sponsored by LABRE—Rio de Janeiro, the DCM (Wonderful City Award) is available to all licensed amateurs for confirmed contacts with stations located in at least 10 Administrative Regions (RA) of the city of Rio de Janeiro (the well-known Brazilian Wonderful City). There are no special endorsements for the DCM Award. Contacts may be made on any date, in any band, and in any mode. Send log of stations worked (call, date, time, band, mode, and report) together with the QSL cards and 5 IRCs to: DCM Award, LABRE—Rio de Janeiro, PO Box 58, 20100 Rio de Janeiro, RJ, Brazil.

THE FIRST BRAZILIAN AMATEUR

In 1909, in the city of Curitiba, state of Parana, South Brazil, Livio Moreira began his first experiments in wireless transmissions. Together with his friend Flavio Luz, they constructed two radios with crystals of carborundum and with antennas sixty-five feet high. In 1910, for the first time, they could exchange signals between their houses, about 1.2 miles of distance. In 1912, when he was in Germany on a governmental mission, he studied what Germany was doing in that field.

After the first World War, Livio continued his experiments, and after hard work he finally built in 1924 a transmitter delivering 10 Watts which he used for his rare contacts. The first broadcast station, founded in his state in the same year, also used this equipment for its transmissions.

After the establishment of the Brazilian Amateur Radio League, he received the callsign PY5AG. Our homages to Livio Moreira—The First Brazilian Amateur.

SWITZERLAND

Peter W. Frey HB9MQM
PO Box 1127
CH-5401 Baden
Switzerland

Switzerland may be the country of breathtaking scenic beauty, the land of banks reportedly solid as a rock, and of cheese famous the world over, but it is certainly not an award hunter's heaven. I know of only two awards issued by local clubs (Old Lucern Award and Lake Zurich Award), and the national society, the Union of Swiss Short Wave Amateurs (USKA) also has just one award to offer—the Helvetia Award.

This last award, named after the tribe of the Helvetians who settled in Central Europe during Caesar's reign, is definitely not an easy one to work. You are required to show proof of contact with stations in all of Switzerland's 26 cantons (or states), many of them smaller than an average county in the United States and some of them with a ham population of fewer than ten amateurs licensed to operate on HF. Whereas it's quite common to get in contact with a station in one of the big city cantons of Zurich, Berne, Basle, or Geneva, it can prove rather frustrating trying to get hold of an amateur in one of the rural cantons like Appenzell-Innerrhoden or Obwalden where there are fewer than five licensed operators! No wonder a German award hunter recently remarked to me, "It's darned-sight easier to work 50 states for the WAS than it is to work 26 cantons for that Swiss award!"

The Helvetia award is issued for HF contacts on or after January 1, 1979, in three categories: CW and/or phone, RTTY, and SSTV. The award can also be worked on 144 MHz, 430 MHz and 1.3 GHz. So far, no diploma has been issued in the RTTY or SSTV categories and only one Swiss amateur has succeeded yet in working all 26 cantons on 23 centimeters. Hansruedi Lauber HB9RG, the proud owner of the first Helvetia award on SHF: "Exactly half of the contacts were made with expeditions staged especially for the purpose of giving me another canton. Without the help of many friends this would not have been possible!"

Expeditions—that is the way to work those rare cantons on HF, too. Expedition time in Switzerland is coming up soon: During the Helvetia contest usually all cantons are put on the air, and this year's affair runs from Saturday, April 23, 1400 UTC until the same time on Sunday, April 24. There is a good chance, for example, to get hold of the canton of Appenzell-Innerrhoden during this contest. Listen for the call sign HB9OE. Or, if you still need that rare canton of Uri, the operators of club station HB9AJ will be happy to be of help. The Helvetia contest runs on all bands from 180 meters to 10 meters, WARC bands excluded, and is a phone/CW affair.

If the Helvetia awards sounds like a challenge to you, why don't you contact USKA's awards manager for a copy of the rules. Write Walter Blattner, PO Box 450, CH-6601 Locarno, Switzerland. If you would like to know more about the Helvetia contest, the man to contact is USKA's traffic manager, Gody Stalder HB9ZY, Tellenhof, CH-6045 Meggen, Switzerland. Both would appreciate an SAE with two or three IRCs for an airmail reply.

WEST GERMANY

Hans J. Schalk DJ8BT
Hammarskjold-Ring 174
D 6000 Frankfurt 50
West Germany

Ralf Beyer DJ3NW
Opferkamp 14
3300 Braunschweig
West Germany

If the purpose of a contest is the testing of one's own station and operational abilities under difficult conditions, this one may be considered as a contest in the classic meaning. The calls and comments we received after the contest indicated that many alterations of individual FAX stations were made as a result of gained experiences. This first FAX contest resulted in a number of function-related discoveries, not only in a technical sense but also from an operational point of view.

Responses were very positive as a rule and all participants seem to have enjoyed the event. Total participation of about 30 different stations was unexpectedly high. We wish to thank especially the 18 stations which sent in their logs. Class A was well represented with an input of 9 logs. Unfortunately, no log was received for class B. Also, we missed the logs of those amateurs from class C who are usually involved in satellite receiving. Contest traffic took place on 80-, 20-, and 2-meter bands. A maximum of 7 countries could be worked.

The following stations were monitored on shortwave: DF7NF, DF7XA, DF0BUS, DJ8BT, DL2XP, DL6FAG, DL6LAG, EA4TI, F8ACU, F6AEO, F6CDX, G3ZJG, G4KGB, HB9BZY, LX1BC, LX1PO, LX1SW, LX2FD, and OE9AHI. Also on UKW were QRV: DB2HA, DB4LM, DB0DB, DD8BP, and DL9LAG.

The conditions on 80 and 20 meters were satisfactory, depending on the time of day. Conscious interference by CW, RTTY, and/or SSB stations could not be observed, and we are grateful to these operators. The contest rules have proved valid, in our opinion, but rules for the next contest will have to be revised in connection with club stations.

We wish to express our gratitude in the name of the German Amateur Radio Club (DARC) to all contestants and their efforts. Our congratulations for the winners of class A and C. All contestants who sent in their logs to the first DARC FAX contest will receive a certificate in remembrance of this event.

CONTEST 1983 DARC "CORONA" 10-METER RTTY

DARC has the great pleasure to invite radio amateurs worldwide to participate in the annual 10-Meter RTTY Contest, which is held to increase RTTY activity on the 10-Meter amateur band. There will be four tests through the year. Each test scores separately.

Schedule: 1st Test, March 5th, 1100-1700 UTC; 2nd Test, May 8th, 1100-1700 UTC; 3rd Test, September 3rd, 1100-1700 UTC; 4th Test, November 8th, 1100-1700 UTC.

Band: The recommended portions of 10 Meters.

Contest Call: CO CORONA TEST.

Exchange: RST/QSO Nr./Name

Points: Each station to be contacted once only. Each complete 2-way RTTY QSO is worth 1 point.

Multiplier: Use the WAE and DXCC country list, add each district in W/K, VE/VO and VK.

Scoring: Total multipliers times total number of QSOs.

Classes: A—Single or multi-operator; B—SWL printer.

Logs: Must contain name, call, and full address of participant/Class/Time in UTC/Exchange/Final score. SWL printers apply according to the rules.

Deadline: Each entry must be received by the manager within 30 days after each test.

Manager: Klaus Zielski DF7FB, PO Box 147, D 6455 Erlensee, West Germany.

Plaques: Will be awarded to the leading

RESULTS OF THE FIRST DARC FAX CONTEST

Class A	Points	QSOs	Countries	Bands	Class C	Points	OSO	Countries	Bands

Class B: No input
Checklog: DJ8BT

stations in each class with entries with reasonable scores.

LICENSING

As you may know, reciprocal licensing agreements exist between a number of countries and the Federal Republic of Germany. And it is interesting to know which choices you have to obtain a license in this country.

First, the class of license you may apply for: Class A requires something like a Novice or Technician ticket. It allows a maximum power output of 150 Watts or, alternatively, a rig with a maximum plate/collector dissipation (manufacturer's data) in the final amplifier of 50 Watts. You are allowed to operate from 3520-3600 kHz and 21090-21150 kHz in CW and RTTY and from 3600-3700 kHz in AM/SSB. From 28.0-29.7 MHz and 144-146 MHz you may use CW, AM/SSB, RTTY, and narrowband TV.

If you have something like a General or higher ticket, you may apply for a class B license. The power levels permitted are different for individual groups of bands and are indicated in the form of maximum power output/maximum plate or collector dissipation. The following bands are available: 1815-1835 kHz and 1850-1890 kHz for CW and 1832-1835 kHz for CW and SSB at a power level of 75/10 Watts, 3500-3800 kHz, 7000-7100 kHz, 14000-14350 kHz, 21000-21450 kHz, 28.0-29.7 MHz, and 144-146 MHz for CW, AM/SSB, RTTY, and narrowband TV at a power level of 750/150 Watts. The 10100-10150 kHz, 18068-18168 kHz, and 24890-24990 kHz bands are reserved for CW only at a power level of 150/50 Watts. The band subdivisions are governed by the IARU recommendations.

The class C license is a no-code license for 2 meters and up. No comparable counterpart exists in the US. However, amateurs from other countries with a similar license may apply for class C and enjoy AM/SSB, RTTY, and narrowband TV on these bands.

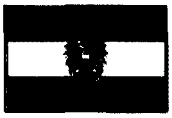
There are several ways to apply. If you are visiting the country for a period of up to 3 months only, you should apply for a license through the German Amateur Radio Association (Deutscher Amateur Radio Club e.V. (DARC), Postfach 1155, 3507 Baunatal 1, Federal Republic of Germany). No particular forms are required but you should state your nationality, full name, date and location of birth, home address, domestic call and class of license, membership in an amateur radio association if applicable, the 3-month period for which a license is desired, your address in Germany and/or the license plate number of your car, a copy of your domestic license, a statement that you have transferred the fee of DM 15.00 to DARC, and a mailing address for your German license after issuance. The DARC will check your application and forward it to the responsible directorate (Oberpostdirektion Duesseldorf) of the German Department of Telecommunications. After 4-6 weeks you will get your license from there with a call like DH/W8XYZ for class A or DL/W8XYZ for class B.

In case you are a civilian staying in Germany for more than 3 months, the procedure is different but not much more difficult. You have to apply directly to the directorate of the Department of Telecommunications of the state you are living in. They will send you the appropriate form on request. But as you have to present a residence permit and a certificate of good conduct, you should be living in the country already before writing your application. Your call will be taken from the DJ0AAA-DJ0ZZZ block with a two- or or three-letter suffix. The annual fee is DM 36.00 (about $15.00).

All applications by military personnel have to be addressed to the responsible section of your unit, which will get in touch with the German Department of Telecommunications directly and provide you with all the information you need. You will be assigned a callsign from the DA1AA-DA2ZZ block.

This is a very brief run-down of what you may expect when applying for a license in Germany. Of course, there is much more in store like operation above 2 meters, getting a license if you have no domestic license, using broadband TV or telecommand modes and so on. These and other topics are covered in full detail in the brochure *Bestimmungen ueber den Amateurfunkdienst* which is much more elaborate than its translations *(Regulations Concerning the Amateur Service* or *Reglement relatif au service d'amateur)*. Copies may be obtained from the Bundesministerium fuer das Post und Fernmeldewesen, 5300 Bonn 1, Federal Republic of Germany.

But best of all: On special events, like international radio amateur conventions in Germany, you may get a license on-site, free of charge, without filling in special forms, and good for 1 week. So have your domestic license always handy when you visit Germany and enjoy some of the most liberal amateur radio regulations in the world.



AUSTRIA

Dr. Ronald Eisenwagner OE3REB
PO Box 999
A-1014 Vienna
Austria

Austria, located in the central part of Europe, has today about 4500 radio amateurs. There is one big society, the OVSV (Osterreichischer Versuchssenderverband), which is a member of the IARU, Region 1. A good 4200 of these radio amateurs are members of the OVSV. The activity is very varied. There are about 40% with permission to operate on all bands; real DX activity is poor. Not more than 200 amateurs can be heard in international traffic and most of the operators can be heard only on the repeaters.

We have two different types of licenses in Austria; one is a General license, which gives the owner the permission to work on all bands and in all modes. For this license, one needs to pass a CW examination at 12 wpm. The other type of license (without a CW examination) gives the possibility to work 144 MHz and above, phone and RTTY only. Repeater activity is big, especially in and around bigger cities such as Vienna, Linz, Salzburg, Innsbruck, and Graz. There are more than 25 repeaters for 2m and a good 15 for 70cm in operation, but as elsewhere, the activity is great only in the morning and evening hours and on weekends. There are some groups with SSB and CW activity on the UHF bands, too, but only a very few are operating in the EME circuits.

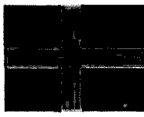
Hearing an Austrian can tell you some information as soon as the call is recognized. The number (1 up to 9) tells you the area from which the station is transmitting. OE1 = Vienna, OE2 = Salzburg, OE3 = Lower Austria, OE4 = Burgenland, OE5 = Upper Austria, OE6 = Steiermark, OE7 = Tirol, OE8 = Karnten, and OE9 = Vorarlberg. The number 0 is not used currently. Normally, the first part of the call is followed by two or three letters. Each letter combination can be found only once in Austria! The administration has put out three-letter calls in the last 15 years, so the owners of two-letter calls have been radio amateurs at least 17 years! For special purposes, the first letter can give further information: X stands for a club station (e.g., OE1XA, the club station of the OVSV, district Vienna), Y for a young lady, and Z for a guest license with permission to operate for more than three months. If a station is portable, it has to put on the end of the call the area locator (e.g., OE1XA/3). For short-time guest licenses one takes one's own call and adds OE on the end (e.g., WB2VMM/OE). No problem to get a guest license, but please keep in mind that everything needs time here, hi!

The technical activities are very varied. There are still many putting together their own gear, or at least parts of it, but most Austrians prefer to walk around the corner and buy the rig. There is not a broad variety of equipment on the market, but one can get nearly every station. Most of the boys are using Japanese gear, but there are also a good number of Drake users. Collins is well known but rather expensive, so one finds only some older models; haven't heard of a new KWM380 in use here.

A whole variety of antennas is in use—mostly Fritzel from Germany, but also Hy-Gain, and some of the top DXers are riding on KLM and more expensive beams. There is not too much antenna home-brewing; most prefer to buy one and put it up! As 99% of the amateurs are limited in space one does not find special antennas for the low bands (and you will find few OEs on 160 and 80). There is no rotatable 80m beam in action here and only a few 2el for 40 from Hy-Gain. So for the low bands one prefers dipoles, verticals, and some forms of longwires. As we are also limited in power, it is a rather difficult job to be in a DX fight!

Presently, the upper limit for personal calls is 400 W HF power output. Club stations are allowed to run 1-kW output. With a new regulation, it is possible to own commercial linears such as the L4B, L7, SB200, and SB220. Before, when we had been limited to 100 W anode dissipation power, most of the linears had been home-brew ones with 4 to 6 TV tubes in them (or a black box below the table, hi). That time is over now, and we hope that with final new regulations, which are expected at the end of 1983, we will be allowed to run 1 kW.

The connection to our PTT is everything between very good and "like a family," but as a good father does with his children, they keep an eye on us! Being on the wrong way can cost some $50 to $100 and in some cases one can lose the license altogether (hasn't happened in recent years).



SWEDEN

Rune Wande SM0COP
Frejavagen 10
S-155 00 Nykvarn
Sweden

Amateur radio is unique in its way of bringing people from all over the world together on a man-to-man communication basis. We feel like we know each other very well thanks to our common interest. Although the amateur radio regulations in all countries are based on the same international ITU regulations, amateurs in various countries are facing different laws. Most of us are not aware of these differences.

This new section will cover amateur radio in Sweden mainly, but being so closely related to the other Scandinavian countries historically and linguistically, news concerning laws and operations in Denmark and Norway will also be dealt with—and also Finland.

In a wider sense, one can talk about the Nordic countries all together and include more or less exotic prefixes like JW, JX, JY, OX, OY, FT, and even 3Y Bouvet in the South Atlantic Ocean. All of these are in some way related to either Denmark or Norway and usually have similar regulations for ham radio.

That there still are considerable differences among these countries, however, has become obvious by the efforts made to institute a common Nordic License. Apart from the sensitive east-west relations because of our geographical location, there are other factors causing difficulties in achieving this. Sweden has four classes of licenses, while the others have only two. Denmark, Finland, and Norway require a code proficiency of 12 wpm for their highest class of license while Sweden requires 16 wpm. Sweden has one class of license for VHF/UHF without code requirement; this is different from the other countries. Finland does not allow mobile operation by a foreigner operating from there. The new WARC bands have been opened for the other countries, but all that Sweden has opened so far is 15 kHz on the 160m band with 10 W input from April 1, 1982. There also are different maximum power levels in these countries. Finland has a maximum power level of 600 Watts output compared to 500 Watts dc input in Sweden.

Today a reciprocal license has to be applied for and a license fee paid when visiting a neighboring country. A reciprocal license in most European countries is valid only for three months per calendar year, and processing time can be over three months long. In a future column I will give specific information on how to apply for reciprocal licenses in Scandinavia and in Finland.

The Swedish Telecommunications Commission (Televerket) has just recently revised our amateur regulations. In a coming column I will tell about the requirements for obtaining a ham license in Sweden and make comparisons with the other countries. I will talk also about the privileges we have and make comparisons with yours in North America.

MULTI-BAND SLOPERS

160, 80, and 40 meters

Outstanding DX performance of slopers is well known. Now you can enjoy 2 or 3 band BIG-SIGNAL reports! Automatic bandswitching • Very low SWR • Coax feed • 2kw power • Compact • Ground or tower feed • Hang from any support 25 ft. high or higher • Easy to install • Very low profile • Complete instructions • Immediate shipment • Check ok

3 BAND SLOPER · 160, 80, & 40 Meters	60 ft. long	$ 43.00 frt ppd
2 BAND SLOPER · 80 & 40 Meters	41 ft. long	$ 30.00 frt ppd
3-BAND NO TRAP DIPOLE, 160, 80, & 40M	113 ft. long	$ 66.00 frt ppd
2-BAND NO TRAP DIPOLE, 80, & 40M	84 ft. long	$ 49.00 frt ppd

The Florida T-R Switch

Get your 2m amplifier out of the way—without a relay.

I had quite a bit of fun being QRP mobile with my TR-2200A and a quarter-wave whip; it's amazing how little power you need to work into the repeaters and even to work simplex. However, it is quite frustrating to need to get out and not be able to. I was, therefore, very interested in the two articles that appeared in *73* (November, 1977 and December, 1977) describing how to build a small amplifier using any of a number of available transistors.

I chose to build the WA2INM variety, but without the COR. The amplifier worked great (getting about 10 Watts out with two Watts input), but no means existed for T-R switching.

A variation of the scheme in W4MNW's design was tried and it worked great. This amounted to the addition of two 1/4 wavelengths of RG-174 as shown in Fig. 1. When receiving, the low level rf is below the threshold to cause the diodes to conduct, so there is a direct path from the antenna to the receiver around the amplifier. Any attenuation from shunting is negligible since the impedance of the tuned circuits is sufficiently high. When transmitting, the high level rf causes the diodes to conduct, which produces a short at the midpoint. The impedance one-quarter wavelength away from a short is high; therefore, the rf passes through the amplifier to the antenna. No T-R switching was used for the 12-volt supply since the amplifier operates class C and no current is drawn until it is excited. A power switch should be provided to apply the 12 V dc, however. The basic construction is still identical to the original amplifier.

Both Jim WA4GND and I have been using one of these units for quite a while and have had excellent results. There has been no noticeable degradation of receiver sensitivity with the diode switching arrangement, and it sure beats having to repeat the call several times. ■

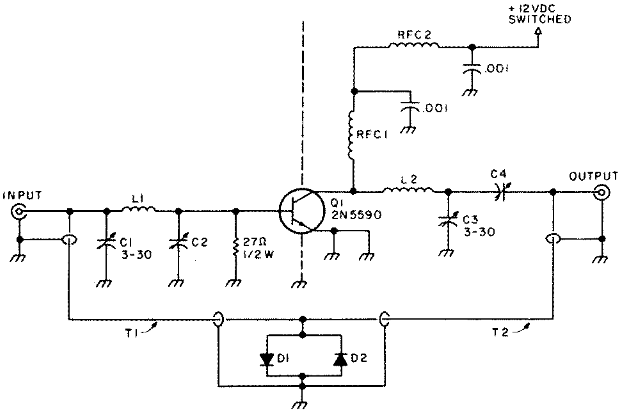

Fig. 1. Amplifier schematic. C2—68 pF mica in parallel with 7-45 pF trimmer; C4—7-45 pF trimmer; D1,D2—1N914; L1,L2—2-1/2 T, #22 solid wire, 1/4" dia., spaced 3/4"; RFC1, RFC2—approx. 6 T #22 PE, 1/4" dia., close-spaced; T1,T2—1/4λ, RG-174 (approx. 13-1/2").

COMPARE the HAZER™
with foldover + telescoping towers

- Antenna systems mount on Hazer-Hazer follows parallel to outside of tower - Raise to tower top or lower completely to ground level.
- Safety lock system on Hazer operates while raising-lowering & in normal position. Never can fall.
- Weight transferred directly to tower. Winch cable used only for raising & lowering.
- Will support most antenna arrays up to 20 sq. ft.
- High quality materials & workmanship
- Safety - speed - convenience - smooth travel
- Ease to install and use
- For Rohn 20 & 25 tower — Other towers on request

Complete with winch, 100 ft. of cable, hardware and instructions.

HAZER II Heavy alum. $279.95 - $17.00 UPS
HAZER III Standard alum. $199.95 - $13.00 UPS
HAZER IV Heavy gal. steel $249.95 - $28.00 UPS

Specify mast diameter when ordering.

Build the Deadeye Dish Controller

Tired of taking potshots at satellites? With the flick of a switch, this easy-to-build rotator will hit the bull's-eye every time.

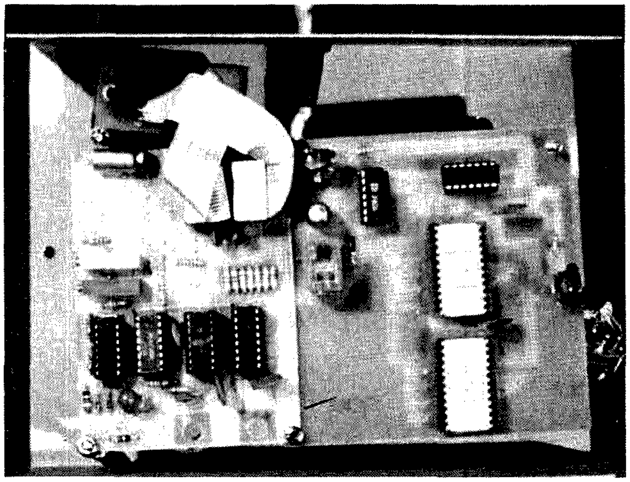

Photo A. Interior view of the cabinet, showing the Motorola kit and the control board.

Lindsey Riddle W5JG
5646 Bellaire Drive
New Orleans LA 70124

Want to stop your TVRO dish on a chosen satellite with a minimum amount of effort? With this system the dish can be changed many times during an evening of viewing without requiring you to get out of your chair.

It is possible with a properly aligned polar mount and dish to swing the dish through a complete orbit (horizon to horizon) and stay properly lined up. (See *Coop's Satellite Digest*, June, 1981, "Polar Mount For All Seasons.") To accomplish this, the BCD (Binary Coded Decimal) of an analog-to-decimal converter (A/D) that is used to show a relative digital readout of the position of the dish is used to open the holding contacts of a relay when the readout of a chosen satellite comes up.

For quite some time, I had been looking for a simple A/D converter that would show the look angle of a

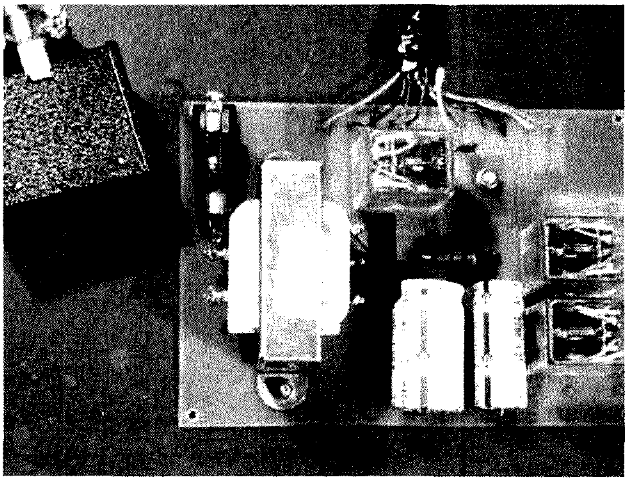

Photo B. The power supply and cable.

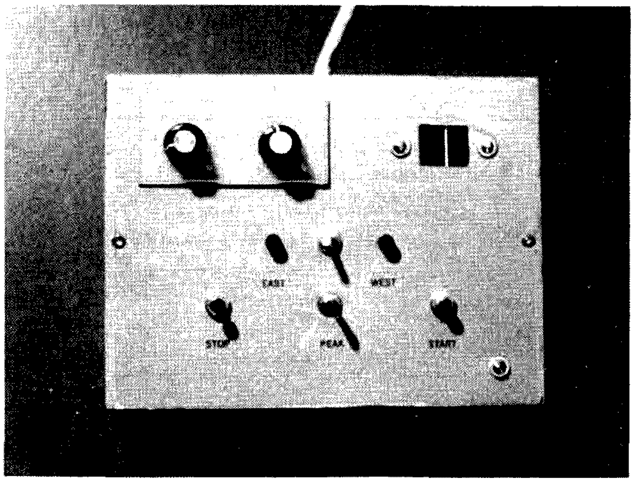

Photo C. Dish control cabinet.

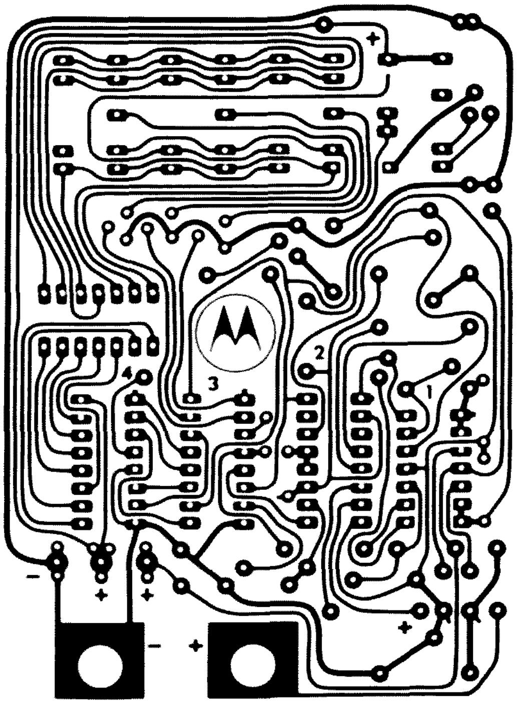

Fig. 1. Motorola PC board (foil side).

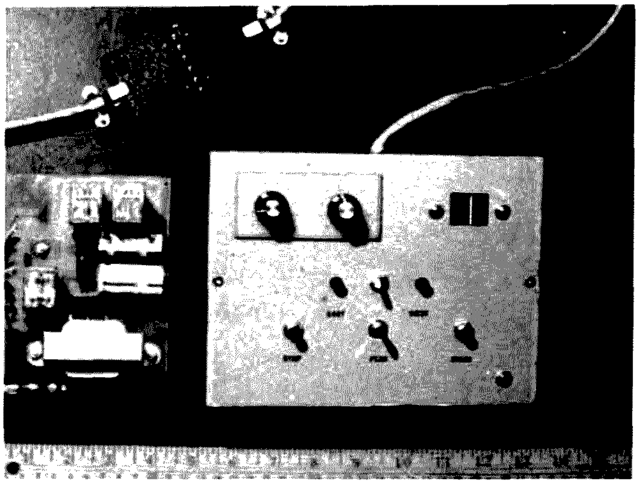

Photo D. Cabinet, power supply, and connector.

dish while allowing the BCDs to be available to control relays, etc. The Motorola 3½-digit voltmeter talking kit had all these features except that it was a strobed unit and I was unable to find a method to interface it to a relay. The unit was sent to Ira Miller of Motorola, and he and Joe Carbaico came up with a strobed BCD-to-line driver (MC 14514) that would allow this to be accomplished.

This article was completed and almost ready to be sent in when disaster struck. It was discovered that the kit had been discontinued. Upon checking with Motorola, I found out that all parts were available except the circuit board. Luckily, I had one on hand, and it was possible to make a film negative. The kit included only the board and the four ICs. The chips are now available from Circuit Specialists, Box 3047, Scottsdale AZ 85257 (MC 3403P, $1.30; MC 1405L, $8.95; MC 14435, $5.95; MC 14511, $1.44). Fig. 1 shows the one-sided board; it measures $2\frac{7}{8}$" × $3\frac{15}{16}$".

Theory of Operation

Potentiometer 1 (Fig. 3) is

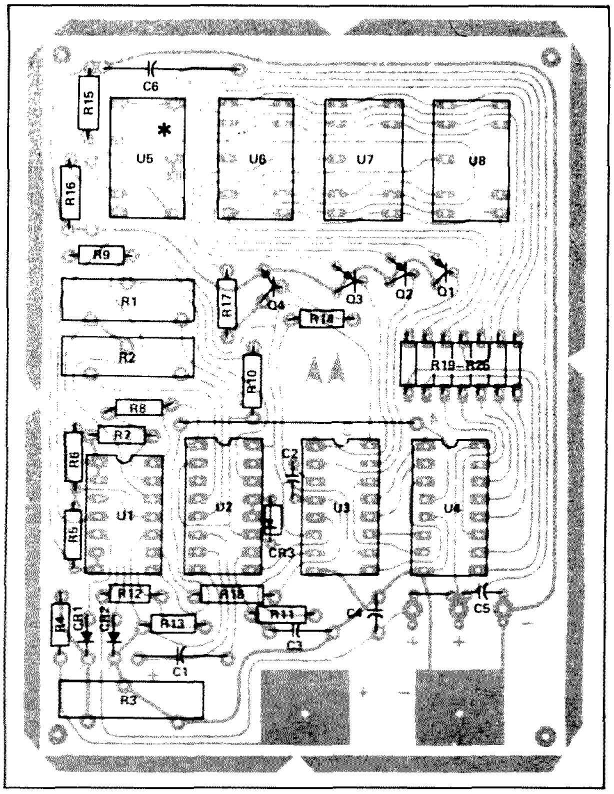

Fig. 2(a). Motorola PC board (component side).

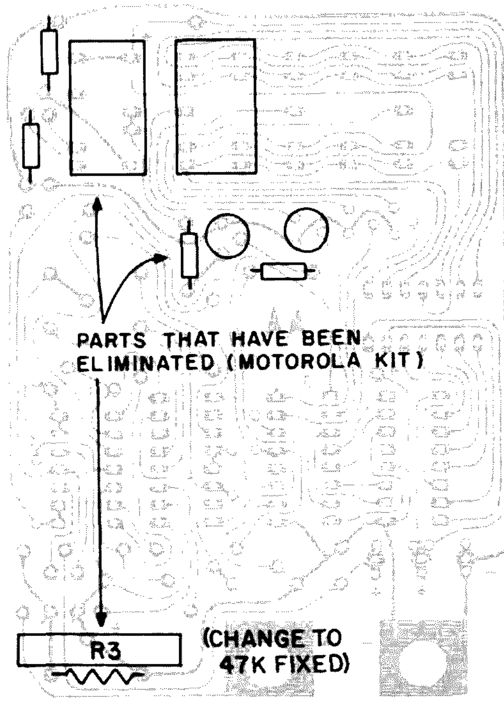

Fig. 2(b). Component side of the Motorola board showing which parts are not used.

mounted so that it turns with the dish and feeds a small varying voltage to the A/D converter; the converter gives a relative readout of the position of the dish. The BCD of the converter is tapped and fed to two MC 14514s (U9, U10)—a 4-bit latch-to-line driver. The converter is not disturbed by this and operates in a normal fashion. A 14514 will take a BCD signal at its input and come out with a pulse on the proper output. It has 10 outputs, so with a 10-position switch it is possible to select any number from 0 to 9. With two 14514s and two switches (SW1, SW2), we can select any number from 0 to 99.

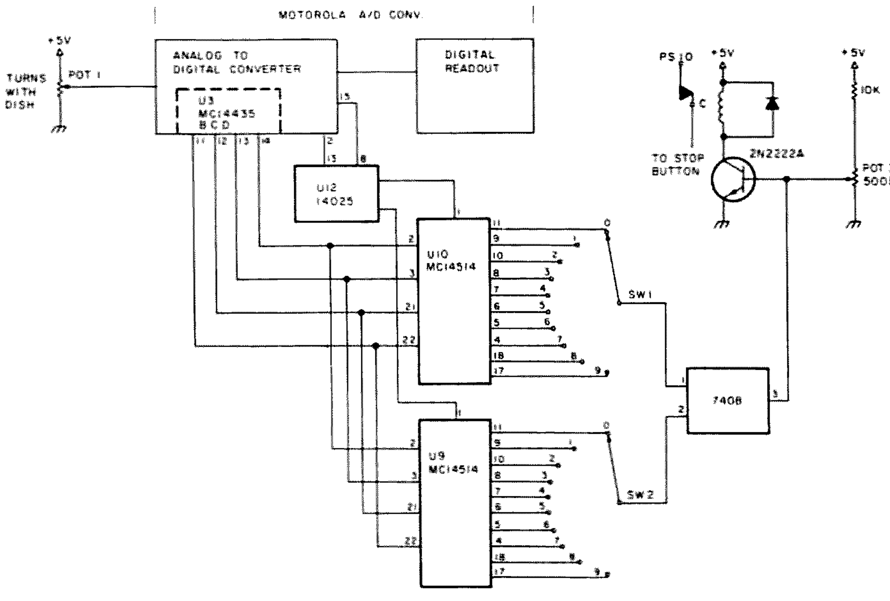

Fig. 3. Theory of operation.

The outputs of the two switches are fed to the two inputs of a 7408 (U11, 2-input positive AND gate). There will be an output pulse of the 7408 only when there are pulses present at both inputs at the same time. When the 7408 has an output pulse it will trigger the 2N2222A causing Relay 4 to open; that breaks the return ground of holding Relay 1 and kills the power to the motor that is turning the dish. The 14025 (U12) takes

"HAL" HAROLD C. NOWLAND W8ZXH

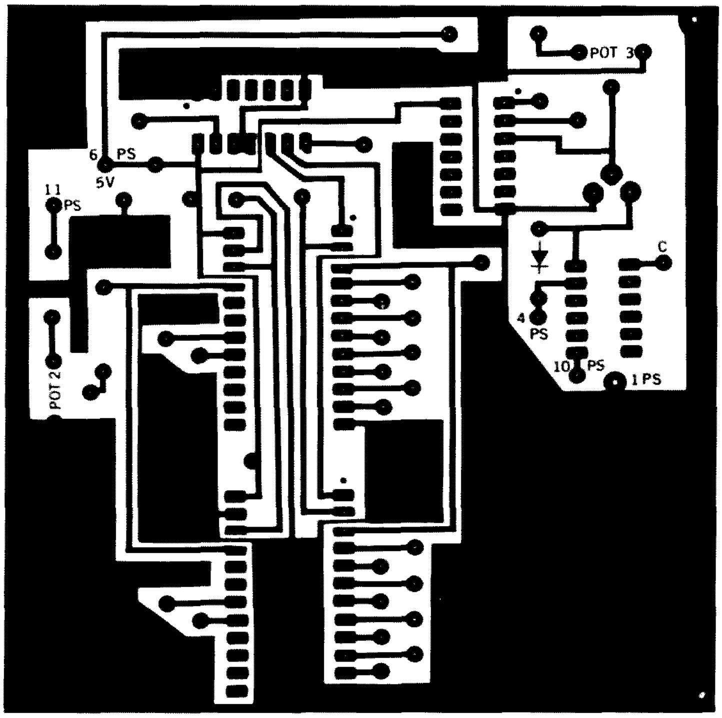

Fig. 7. Control PC board (foil side).

the strobe of the 14435 and turns on the line drivers at the proper time.

Construction

The unit is constructed in a Radio Shack cabinet. Unfortunately, this is a steel cabinet and is hard to work with. Fig. 4 shows the layout of the panel. The panel holds the switches 1 through 6, two LEDs (east and west), and the two MAN 74 readouts (U7, U8). The readouts are mounted on a PC board that should be etched for this purpose (Fig. 5). The board should be mounted on the panel with 6-32 bolts, so the readouts can be made flush with the panel.

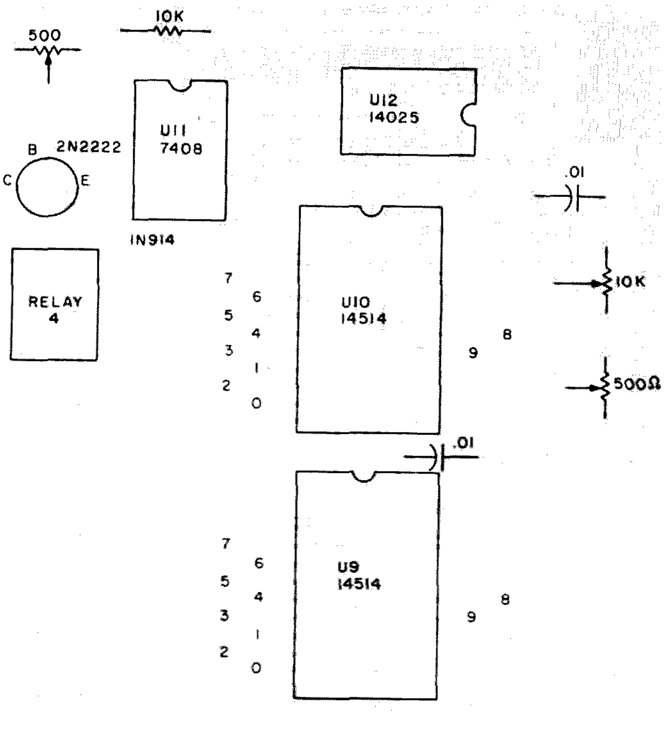

Fig. 8. Control PC board (component side).

Plug-in DIP jumpers can be used to extend the readouts to the board. A double 14-pin DIP jumper with 12 inches of ribbon cable can be cut in the middle, giving six inches for each readout. Since it is necessary to extend only 10 leads for each readout, small flexible wire could also be used with headers. For SW1 and SW2, small wire is better than ribbon wire. Leave enough slack so that the panel can be turned back for servicing. Fig. 6 is for an etched board that marks the positions of the switches.

The A/D and the control board (Fig. 7) are joined together with a couple of 4-40 bolts. The A/D board should be on top to eliminate any chance of a short. Before the boards are mounted in the cabinet, the following wiring should be done: The four BCD outputs of the MC 14435 (U3) must be connected to the already-paralleled inputs of the 14514s (see Fig. 13). Number 2 pins should connect to pin 14 of the 14435, #3 pins to 13, #21 pins to 12, and #22 pins to 11.

To strobe, pin 13 of the 14025 (U12) should be connected to pin 2 and pin 8 should be connected to pin 15; by reversing, these two lines will change the order of SW1 and SW2. The wires for these switches should be connected before the board is mounted. The boards should be grounded to each other, and the 5 V extended from PS6 to the A/D 5-V in.

Relay 4 fits into a 12-pin socket, so a couple of pins can be ground off a 14-pin socket. Some kind of marking should be put on the relay and socket since the relay is not marked. It is difficult to plug the 24-pin ICs in-

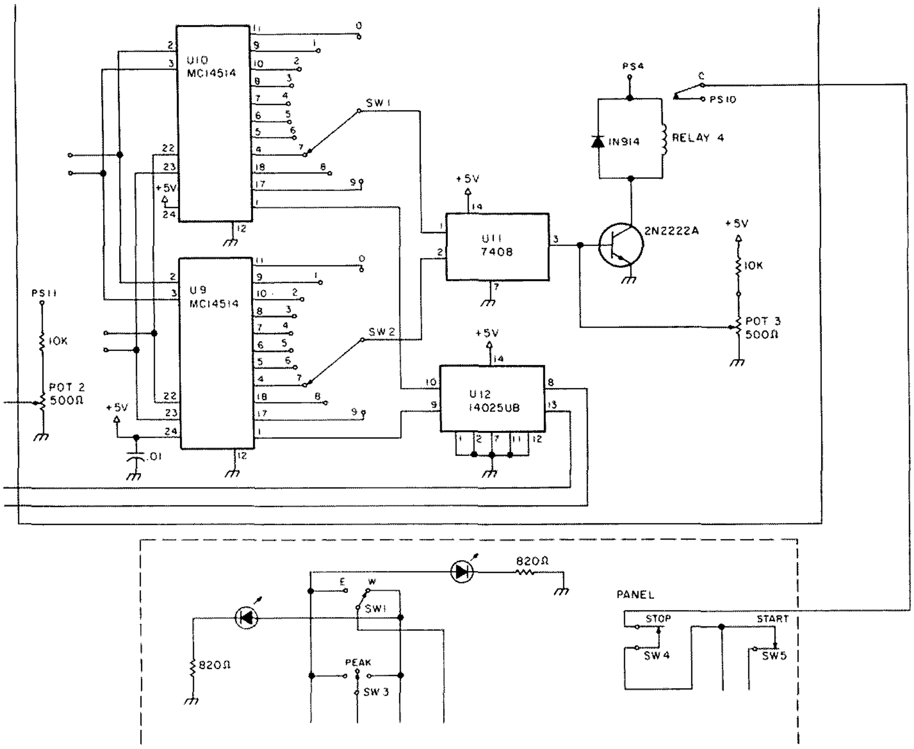

Fig. 9. Control panel schematic.

to a new socket, so I broke it in by using one side of a 14-pin IC, working it around a couple of times.

The boards are mounted in the cabinet by using a couple of long 6-32 bolts and nuts; after the bolts have been made secure, they should be bent parallel with the front and back cabinet. With nuts on the bolts, it is possible to secure the boards so they do not push against the switches but will allow the cabinet to close (Photo A).

A 13-wire cable can be used to connect the control unit that is located at the receiver location to the power supply that is located at the dish. The board has the relays to start, reverse, and stop the motor.

The power supply (Fig. 10) should be installed in a weatherproof box large enough to permit a female chassis connector to be installed in the bottom side. I used an 18-wire cable and 18-prong Jones connector in case more wires are needed at a later date (Photo B). The female chassis connector in the power-supply box is paralleled with the cable so that the control unit can be taken to the dish if necessary. The ac power for the power supply can come from the TVRO receiver if one wants the unit to go on and off with the receiver; otherwise, it can be fed from the dish location.

The construction of the power supply is straightforward except that the 7805 is

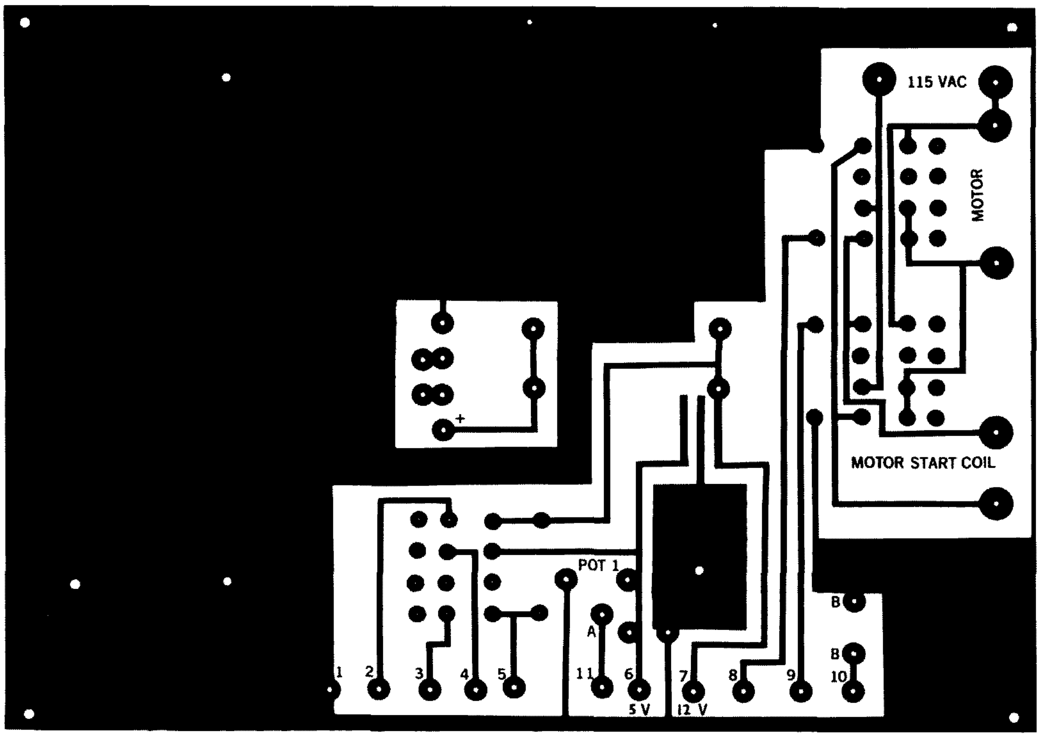

Fig. 10. Power supply PC board (foil side).

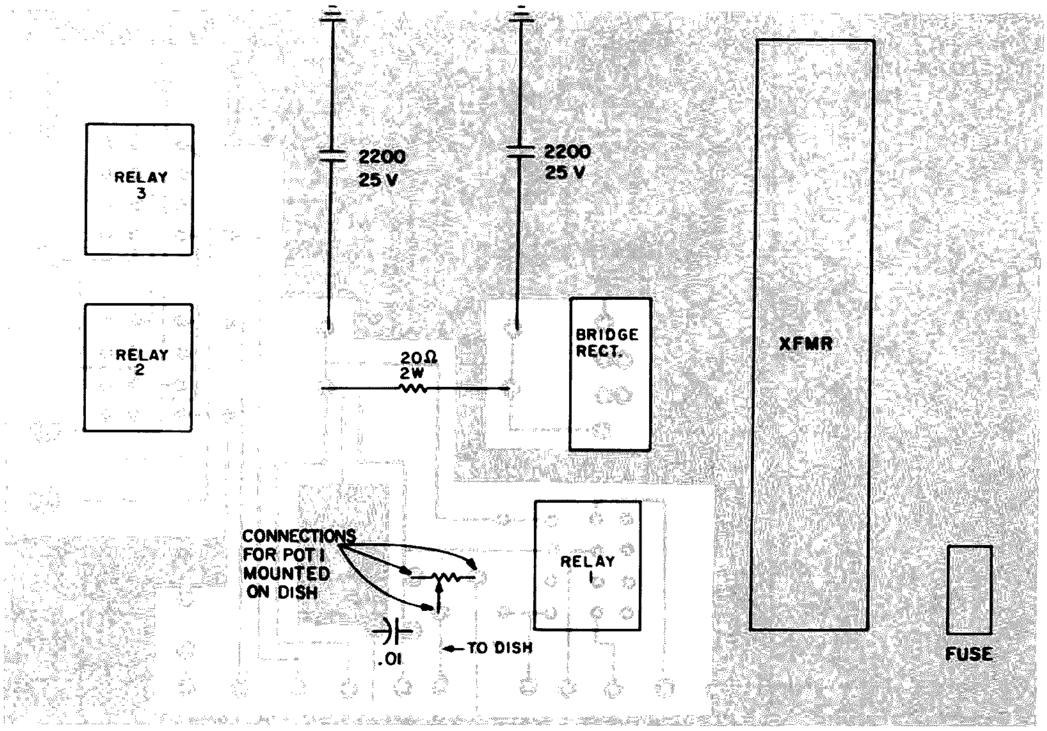

Fig. 11. Power supply PC board (component side).

mounted on the trace side. You should make sure that the 7805 supplies at least 5 V. If it does not, the relays will not operate correctly. If a heavy-duty motor is used, the 3-Amp relays may not be heavy enough, so heavier relays might have to be substituted on a separate mounting. If a permanent-magnet-type motor is used, it would be connected in place of the starting coil. A #54 drill is used for the relays, and a #55 for the bridge rectifier and the 2-Watt resistor.

Knowing that all equipment is subject to failure, I used two mechanical switches (one for the east, one for the west) that will open if the dish turns too far. These switches are connected in the ground return of the holding relay and are connected at BB on the power-supply board. If the switches are not used, B and B should be connected with jumper wires. I also have two other mechanical switches in the ac line which open in case the other switches fail.

Pot 1 at the dish is installed so that it turns with the dish, and it will not be turned off completely on F1 (135° West). The safety switches, if used, should be set so that they will open before the pot reaches its limit of turning. If the reading is backwards, the 5 V and ground leads should be reversed.

The A/D converter is lined up by setting R1 so that the output of R1 is 1 volt. Pot 2 on the control board is adjusted so that when the dish is on the most westerly direction (F1) the reading will be around 5. This will give the most easterly direction (F4—83°) a reading of approximately 60. Pot 3 is adjusted so that each time the 2N2222A receives a pulse, Relay 4 will open. In this adjustment, remember that there will be no power to R4 until the holding relay is closed.

Should you desire to mark the panel (Photo C), dry transfer letters are excellent. Such letters can be removed easily with Scotch tape. After labeling, spray on a thin coat of Krylon™. The Krylon and letters soon wear off, so they should be protected with a sheet of clear mylar™. (Sheet mylar with adhesive on one side can be purchased from office supply houses.) The mylar wants to peel, so with an X-acto® knife trim about 1/8" off around the edges of the panel.

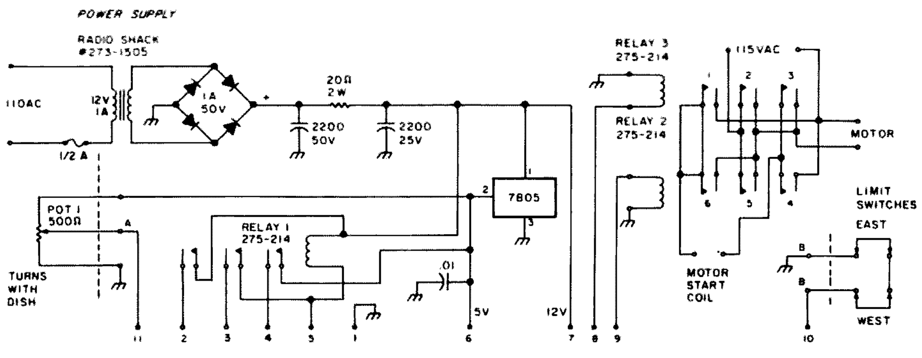

Fig. 12. Power supply schematic.

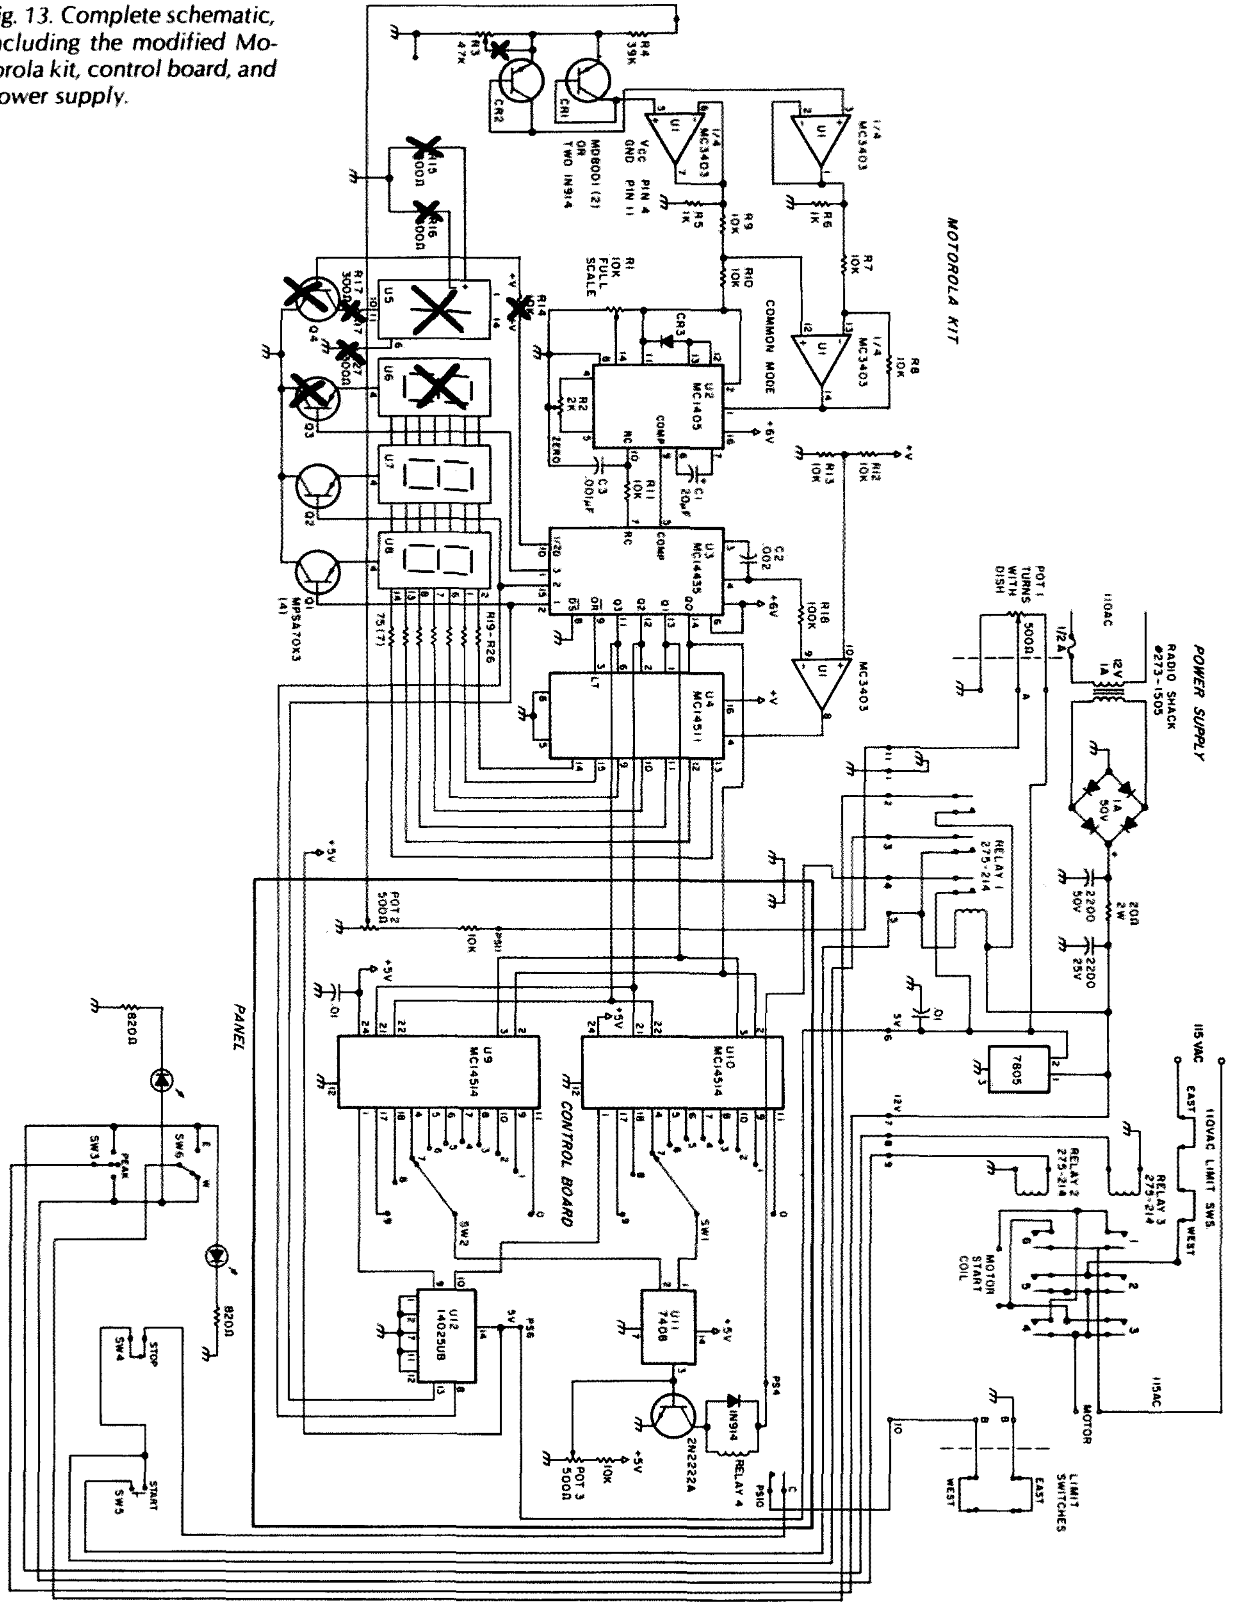
Operation

To operate the unit, it is necessary to put the two dial switches on the readout number of the chosen satellite, flip the east-west switch in the direction the dish must turn, press the start button, and wait for the dish

Fig. 13. Complete schematic, including the modified Motorola kit, control board, and power supply.



to move to the new satellite and stop. On weak transponders, it might be necessary to peak the dish. This is done with the peak switch, SW3.

Since there are no holding contacts, the dish will stop as soon as the switch is released.

It would have been possible to eliminate the east-west switch and use pushbutton switches instead of the mechanical switches, but after using this method for quite some time, I decided that the extra circuitry, memories, etc., were not worth the details involved. If one wants to connect it to

a computer, this can be done simply by using only a 4-PDT switch in the BCD lines to get the BCD information from the computer.

Since most ham antenna rotators feed back a small varying voltage for the meter reading, it may be possible to control a ham antenna by adding another readout for 360°.

After putting this unit into operation, you will be pleased with the convenience it offers of scanning the satellites with hardly any effort, and you will be looking forward to the next project. ■

Take your favorite H.T. out for a drive tonight.

VISA or MASTERCARD for same day shipment.

For $69.95 you get the most efficient, dependable, fully guaranteed 35W 2 meter amp kit for your handy talkie money can buy.

Now you can save your batteries by operating your H.T. on low power and still get out like a mobile rig. The model 335A produces 35 watts out with an input of 3 watts, and 15 watts out with only 1 watt in. Compatible with IC-2AT, TR-2400, Yaesu, Wilson & Tempo! Other 2 meter models are available with outputs of 25W and 75W, in addition to a 100W amplifier kit for 430MHZ. ✓382

Communication Concepts Inc. 2648 N. Aragon Ave., Dayton, OH 45420 (513) 296-1411

HOT ROD ANTENNA

Achieve 1 or 2 db gain over ANY ¼ wave two meter telescopic antenna. The AEA model HR-1 Hot Rod™ antenna was designed by Dr. D.K. Reynolds (designer of the IsoPole) to deliver maximum performance for any hand-held transceiver with a BNC fitting.

The factory-tuned HR-1 is 20% shorter, lighter and places far less stress on your hand-held connector and case. It will easily handle over 25 watts of power, making it an excellent emergency base or mobile antenna. In the collapsed position, the Hot Rod antenna will perform like a helical quarter wave.

The Hot Rod antennas can be expected to make the same improvement to hand-held communications that the IsoPole brand antennas have made to base station operations. Why pay more when the best costs less?

The Ultimate Protection Plan for Your HT

Bangs, bumps, scrapes, and crashes make life tough for HTs. Make these modifications to protect your investment.

Please don't drop it! How many times have you said this to yourself and others that have examined your handie-talkie (HT)? Well, with the addition of a simple elastic band and clip assembly, your concern is minimized. This idea can be used on any of the popular models such as the Kenwood TR-2500, the Icom IC-2A, a Yaesu model, or any hand-held with provisions by the manufacturer for a belt-clip attachment.

Since there are many times when one does not wish to use a belt-clip or when convenience dictates that one could not be used, the addition of this elastic band (shown in Photo A) may be the answer. The use of a strap may not be new to some of the older hams, as the hand-helds of World War II vintage used a piece of leather behind the hand for support. However, I believe my technique of attachment is worthy of consideration.

I wanted to be able to fully utilize the unit under all conditions, walking, running, driving, etc., and not have to worry about it falling. Yes, the optional wrist strap was tried, but it did not provide the desired security.

I did not wish to alter the case of my new Kenwood TR-2500, and the need to remove the battery pack prompted the development of this project (see Photo B).

Construction

Simple hand tools such as pliers, metal-cutting snips, a

Photos by Gregg A. Haas

Photo A. Rear view of HT, showing attachment of elastic band to metal clip at base.

Photo B. The felt-lined metal clip is easily removed for battery pack changing or charging.

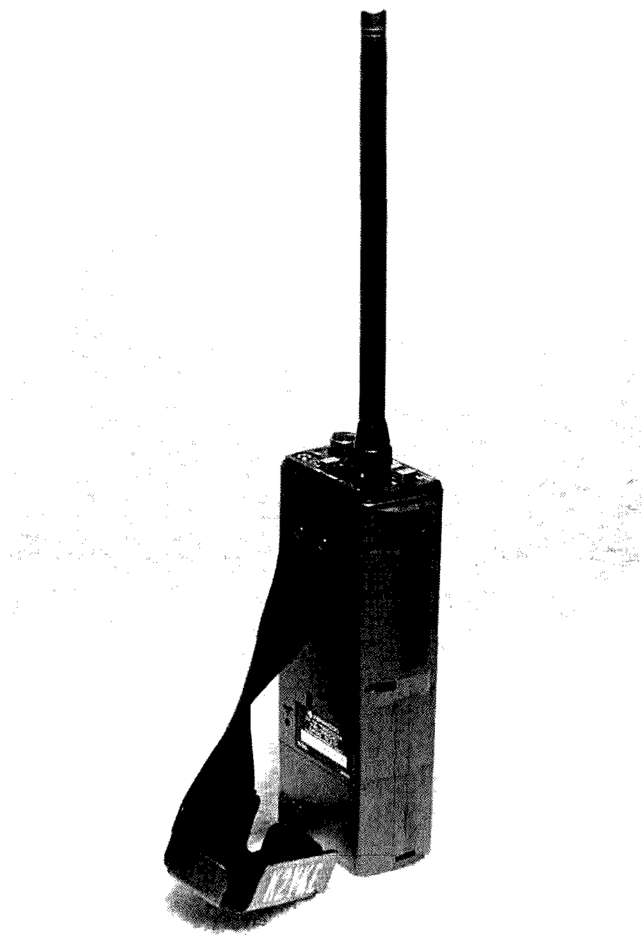

Photo C. *Detail of attachment of band to top rear of unit using the belt-clip mounting nuts already in the unit.*

metal file, a hammer, and a screwdriver will enable the average ham with very little knowledge of metal-working to complete this in a couple of hours.

A piece of aluminum or steel (18-22 gauge) 3½" ×3¾" is used for the clip and two ½"-wide by 1⅞" strips are used like washers over the black elastic. The piece of 2"-wide elastic 6½" long was obtained in a local fabric store along with the thin black felt at least 3½"×3¾". The elastic sells for about $1.25 a yard, so you can see that the 6½" piece cost less than 25¢; the felt 12-inch squares cost 39¢. The only other items necessary to obtain were 2 soft aluminum, flat-head ⅛"-diameter × ¼"-long rivets.

For strength, each end of the elastic was doubled over a distance of ½" and cemented in place with contact cement. Next I cut a ½"×3¼" strip of metal; this in turn was cut in half, leaving 2 pieces ½"×1⅞". The transceiver was set upright upon the remaining metal, centering same on all sides. With a thin felt marker pen, the rig was outlined on the metal. In essence, the base of the HT is used as a pattern for the clip (see Fig. 1).

After cutting along the solid line and before bending into shape, the metal was used as a pattern for the felt liner. When bending has been completed, the eight corners are then slightly rounded with a metal file. The elastic band is attached with the folded side toward the clip and the ½" metal strip on the outside using two soft aluminum rivets with the flat head on the inside. Cementing the felt in place with contact cement completes the assembly. The metal parts were painted with a flat black that appears to blend with any HT finish.

I used the 2 extra screws that came in the accessory package with the TR-2500 to attach the top portion of the band. When attaching the band on the Icom IC-2A, you may use the belt-hook attaching screws. (Caution: Do not use any screws longer than ¼".)

I have had this installation on my HT for some time and, even with gloves on, the slight pressure of the elastic increased the sense of "feel" in using the unit. Lastly, the face of the clip makes an ideal spot for inserting one's call letters (Photo C) without concern for defacing the transceiver.

While I am happy to share this idea and simple construction with readers for their own use, a patent is pending on the design described in this article and commercial application is prohibited. ■

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received at 73 Magazine by the first of the month, two months prior to the month in which the event takes place. Mail to Editorial Offices, 73 Magazine, Pine Street, Peterborough NH 03458.

GRAND JUNCTION CO
APR 2

The Grand Mesa Repeater Society will hold the fourth annual Western Slope Swapfest on Saturday, April 2, 1983, from 10:00 am to 4:00 pm, at the Plumbers and Steamfitters Union Hall, 2364 Highways 6 and 50, Grand Junction CO. Admission is free and swap tables are $5.00 each. Features will include an auction and refreshments. Talk-in on 146.22/.82. For further information, send an SASE to Bill Brown KØUK, 562 So. Maple Street, Fruita CO 81521, or call (303)-858-9661.

ROCHESTER MN
APR 9

The Rochester Amateur Radio Club and the Rochester Repeater Society will sponsor the 6th annual Rochester Area Hamfest on Saturday, April 9, 1983, beginning at 8:30 am, at the John Adams Junior High School, 1525 NW 31 Street, Rochester MN. There will be refreshments, plenty of free parking, and a large, indoor flea market for radio and electronic items. Talk-in on 146.22/.82. For further information, contact RARC, c/o WBØYEE, 2253 Nordic Ct. NW, Rochester MN 55901.

FLEMINGTON NJ
APR 9

The annual Flemington NJ hamfest will be held on Saturday, April 9, 1983, from 6:00 am to 4:00 pm, at the Hunterdon Central High School Field House. Flemington NJ, a tourist area, is located between NYC and Philadelphia at the intersection of routes 202 and 31, just 10 miles south of I-78. Admission is a $3.00 donation. There will be a gigantic flea market with 20,000 square feet of heated indoor area, 200 tables, major manufacturers, and more. Talk-in on 148.52, 147.375, 147.015, 224.12, and 224.54. For reservations or more information, call (201)-786-4080, or write Cherryville Repeater Association, c/o W2FCW, Box 76, Farview Drive, Annandale NJ 08801.

SOMERSWORTH NH
APR 9

The Great Bay Radio Association will hold its 3rd annual hamfest-flea market on Saturday, April 9, 1983, from 9:00 am to 3:00 pm, at the Somersworth Armory, Somersworth NH. The entrance fee is $1.00 per person. Food, refreshments, and free parking will be available. For advance registrations and further information, write Great Bay Radio Association, PO Box 911, Dover NH 03820.

KANSAS CITY MO
APR 9-10

The PHD Amateur Radio Association will sponsor the 1983 Missouri State ARRL Convention on April 9-10, 1983, from 9:00 am to 6:00 pm (both days), at the Trade Mart Building, at Kansas City MO's old airport. Registration is $4.00. Swap tables for both days are $10.00, which includes one registration with each table. The Saturday night banquet at the world-famous Gold Buffet is $19.00. Other features will be a complete program of forums, including DX by the Kansas City DX Club, ARRL by Dave Summers K1ZZ, ARRL General Manager, and 11-meter-to-10-meter conversions by Bob Heil K9EID. There will also be an oldtimers luncheon sponsored by the QCA, a YL luncheon, the Missouri-Kansas Amateur of the Year Award, and the Missouri-Kansas CW Contest Award. Unlimited free parking will be available as well as free space for RVs (no hookups). Talk-in on 146.34/.94. For more information and registrations, write PHD Amateur Radio Association, Inc., PO Box 11, Liberty MO 64068-0011, or phone (816)-781-7313. All preregistrations will be held at the door.

BEDFORD PA
APR 10

The Horseshoe RC, the Blue Knob Repeater Association, the Bedford County RC, the Mountain ARC, and the Somerset ARC will hold the first annual Southern Alleghany Hamfest on April 10, 1983, from 8:00 am to 4:00 pm, at the Bedford Fairgrounds, located at the intersection of Rt. 30 and the Rt. 220 bypass, Bedford PA. Admission is $3.00 per person and inside tables are $5.00. There will be computer demonstrations, food, dealers, displays, an ARRL booth, and plenty of parking. Tailgating space is $2.00 per unit and dealers will be able to set up displays the day before. Large, heated buildings will be available in case of foul weather. Talk-in on 145.49 and 146.52. For more information, contact Tom Gutshall W3BZN at (814)-942-7334.

DIXON IL
APR 10

The 17th annual Rock River ARC Hamfest will be held on Sunday, April 10, 1983, at the Lee County 4-H Center, one mile east of junction of Rtes. 52 and 30. A ticket donation is $2.00 in advance and $2.50 at the gate. Tables (6-foot) will be available for $5.00. Doors will open at 6:30 am for dealers and 7:30 am for the general public. Breakfast and dinner will be served. Talk-in on .37/.97. For more information and advance tickets, write to Ed Webb WD9CJB, 618 Orchard Street, Dixon IL 61021, or phone (815)-284-3811.

MADISON WI
APR 10

The Madison Area Repeater Association, Inc. (MARA), will hold its eleventh annual Madison Swapfest on Sunday, April 10, 1983, at the Dane County Exposition Center Forum Building, Madison WI. Doors will open at 8:00 am for commercial exhibitors and flea-market sellers, and at 9:00 am for the general public. Admission is $2.50 per person in advance and $3.00 at the door. Children twelve and under will be admitted free. Flea-market tables are $4.00 each in advance and $5.00 at the door. Features will include commercial exhibitors, a flea market, an all-you-can-eat pancake breakfast, and a barbecue lunch. Plenty of parking space and nearby hotel accommodations are available. Talk-in on 146.16/.76 (WR9ABT). For reservations (early ones are advised) or more information, write to MARA, PO Box 3403, Madison WI 53704.

FRAMINGHAM MA
APR 10

The Framingham Amateur Radio Association, Inc., will hold its 8th annual spring flea market on Sunday, April 10, 1983, at the Framingham Civic League Building, 214 Concord Street (Route 126), downtown Framingham MA. Admission is $2.00 and doors will be open at 10:00 am. Tables are $10.00 (pre-registration required) and sellers may set up beginning at 8:30 am. Radio equipment, computer gear, and food will be available. Talk-in on .75/.15 and .52. For more information, contact Ron Egalka K1YHM, 3 Driscoll Drive, Framingham MA 01701.

SOUTH SIOUX CITY NE
APR 15-17

The 39 Hundred Club will hold the 1983 Midwest ARRL Convention on Friday, Saturday, and Sunday, April 15-17, 1983, at the Marina Inn, South Sioux City NE, directly across the river from Sioux City. On Saturday, features will include a QCWA breakfast, a 3900 Club luncheon, an all-day ladies' program, and an evening banquet with entertainment. There will be seminars, displays, commercial exhibits, and a 66-table flea market, all indoors in the same building. Tables (8 ft. × 30 in.) are $5.00 for the 3 days, $4.00 for Friday night and Saturday. For table reservations, contact Al Smith WØPEX, 3529 Douglas Street, Sioux City IA 51104. Exhibitors should contact Jim Boise KAØGZY, 22 LaSalle Street, Sioux City IA 51104. Setup time is Friday afternoon, April 15th. Convention fees are $6.00 for the 3 days; advance banquet reservations are $10.00 (at the door, $12.00). For advance banquet tickets and motel reservations, write to Jerry Smith WØDUN, Akron IA 51001. For general information, contact Dick Pitner WØFZO, General Chairman, 2931 Pierce Street, Sioux City IA 51104.

WELLESLEY HILLS MA
APR 16

The Wellesley Amateur Radio Society will hold its annual auction on Saturday, April 16, 1983, at the First Congregational Church of Wellesley Hills, 207 Washington Street, Wellesley Hills MA (located at the intersection of Routes 9 and 16). Doors will open at 9:00 am and the auction will start at 10:00 am. Talk-in on .04/.64, .63/.03, and .52. For further information, contact Kevin P. Kelly WA1YHV, 7 Lawnwood Place, Charlestown MA 02129.

LEAGUE CITY TX
APR 16

The Tidelands Amateur Radio Society (TARS) will hold their 1983 Spring-Fest on Saturday, April 16, 1983, at the fairgrounds in League City TX. There will be free admission and plenty of parking. Breakfast will be served at 7:00 am and activities will begin at 9:00 am. Activities will include a flea market, a swapfest, an auction, dealers' displays, demonstrations, and lunch served between 11:00 am and 1:00 pm. For additional information, contact TARS, PO Box 73, Texas City TX 77590.

OAK RIDGE TN
APR 16

The Oak Ridge ARC will hold the fifth annual Oak Ridge Hamfest on April 16, 1983, from 8:00 am to 5:00 pm, at the Civic Center, Oak Ridge TN. Admission is $2.00 and accompanied children will be admitted free. There will be a large indoor dealer display, an electronics flea market, forums, concessions, and computers. Talk-in on 146.28/.88, 147.72/.12 (backup), and 146.52. For more information, send an SASE to ORARC Hamfest, PO Box 291, Oak Ridge TN 37830.

BRAINTREE MA
APR 17

The South Shore Amateur Radio Club of Braintree MA will hold an indoor flea market on Sunday, April 17, 1983, rain or shine, from 11:00 am to 4:00 pm, at the Viking Club, 410 Quincy Avenue, Braintree MA. The entrance fee is $1.00. Tables (8-foot) are $10.00 each, which includes one free admission. Vendors will be admitted at 10:00 am and there will be plenty of free parking. For advance table reservations, send a check payable to the South Shore Amateur Radio Club to Ed Doherty W1MPT, 236 Wildwood Avenue, Braintree MA 02184. A confirmation of check receipt will be sent and there will be no cancellation refund after April 14. For more information, call Ed at (617)-843-4431, evenings.

RALEIGH NC
APR 17

The Raleigh Amateur Radio Society will hold its 11th annual hamfest on Sunday, April 17, 1983, beginning at 8:00 am, at the Crabtree Valley Mall on US 70 west. Admission is $4.00, with no extra charge for tailgating in the covered flea market. Tables will be available for rental. Features will include a CW contest, a home-brew contest, and special-interest meetings. Talk-in on .04/.64 and .28/.88. For additional information, contact RARS Hamfest, PO Box 17124, Raleigh NC 27619.

DAYTON OH
APRIL

The Washington University Amateur Radio Club will hold a reunion dinner at the Dayton Hamfest. All past members of the club are invited. For more information, contact Washington University ARC WØQEV, Box 1128, St. Louis MO 63130.

BEMIDJI MN
APR 23

The Bemidji Amateur Radio Club will hold its hamfest on April 23, 1983, at the Holiday Inn Convention Center, Highway 2 west, Bemidji MN. Swap tables will be available at the door. Talk-in on 146.13/.73. For more information, send an SASE to Jerry Pottratz WBØMSH, Rt. 8, Box 585, Bemidji MN 56601.

DAYTON OH
APR 29

The 14th annual B*A*S*H will be held on Friday night, April 29, 1983, at the Dayton Hamvention at the Convention Center, Main and Fifth Streets, Dayton OH. Admission is free and parking is available. For further information, contact the Miami Valley FM Association, PO Box 263, Dayton OH 45401.

DAYTON OH
APR 29-MAY 1

The first International VHF/UHF Conference will be held from April 29-May 1, 1983, as part of the Dayton Hamvention, Dayton OH. There will be technical talks and forums with recognized experts, noise-figure and antenna-gain measuring contests, and a hospitality suite get-together with refreshments. For further information, or to advise us of participation in the noise-figure and antenna contests, please contact Jim Stitt WA8ONQ, 311 N. Marshall Road, Middletown OH 45042, or phone (513)-475-4444 (business) or (513)-863-0820 (home).

DAYTON OH
APR 30-MAY 1

The Dayton Amateur Radio Association, Inc., will sponsor the Dayton Hamvention on April 30-May 1, 1983, at the Hara Arena and Exhibition Center, Dayton OH. Admission is $7.00 in advance and $9.00 at the door (valid for all 3 days). Flea-market space is $15.00 in advance and $16.00 at the door. Other features will include forums, new products, exhibits, women's activities, awards, and special group meetings. For special motel rates and reservations, write to Hamvention Housing, 1406 Third National Building, Dayton OH 45402 (no reservations will be accepted by telephone). For other information, write Box 44, Dayton OH 45401, or phone (513)-849-1720. Make checks payable to Dayton Hamvention, Box 2205, Dayton OH 45401.

GREENVILLE SC
APR 30-MAY 1

The Blue Ridge Amateur Radio Society will hold the Greenville Hamfest on Saturday and Sunday, April 30-May 1, 1983, at the American Legion Fairgrounds, White Horse Road, ½ mile north of I-85, Greenville SC. Admission will be $3.00. For advance sales, write Mrs. Sue Chism, Rt. 6, 203 Lanewood Drive, Greenville SC 29607. Talk-in on 146.01/.61 and 223.46/224.06. For further information, write Phil Mullins WD4KTG, Hamfest Chairman, PO Box 99, Simpsonville SC 29681.

NEW! *EASY, FUN KIT!*

New 2 kW tuner kit from TEN-TEC ends constant retuning, guarantees best match, and saves $80! Model 4229 Only $199

Here's the best antenna tuner in amateur radio!

The best quality components, best design, and the best value.
• Reversible "L" circuit guarantees best possible match and widest bandwidth—you may need to tune only once to cover the higher bands and only two or three times on lower bands. • Finest quality parts—ceramic insulators—ceramic inductor form—heavy duty ceramic switch with silver contacts—silver plated roller inductor—• Built-in SWR bridge shows ratios from 1:1 to 5:1 • Built-in 2 kW dual-range watt meter shows power levels from 10 to 2000 watts • Handles 2 kW PEP, 1 kW CW • Frequency range 1.8—30 MHz continuous coverage • Built-in balun—matches variety of antennas, balanced or unbalanced, to 50 ohm unbalanced outputs • Built-in bypass switch • 4-position antenna selector • Coax connectors plus post terminals • Lighted linear dial scale for easy tuning • Black finished aluminum cabinet with stainless steel bail (5½"h x12¾"w x13¼"d) • Also available assembled as Model 229 in slightly different styling at $279.

See your TEN-TEC dealer or write for details:
TEN-TEC, Inc., Highway 411 East, Sevierville, TN 37862.

TEN-TEC

SWR and POWER METER

DPM-1

MACAW's DPM-1 SWR/Power Meter has a frequency range of 1.8 to 150 MHz and a power range of 0-20, 200 and 1000W in three ranges. The DPM-1 is compact, lightweight and measures SWR and power simultaneously, only $44.95. Freight Prepaid Anywhere In U.S. Order by telephone or mail.

SATELLITES

YOU'RE THE EXPERT!

If you are active in amateur satellite communications, it's time for you to share your knowledge with other hams by writing articles for *73*. We are looking for material on a wide variety of satellite topics.

Your fellow amateurs will be particularly interested in learning how to use the Phase IIIB satellite, now scheduled for launching on April 27. Topics in need of articles include antennas (especially for the 1269-MHz uplink), 1269-MHz transmitting systems, and power amplifiers, computer tracking techniques, orbital calculations, operating procedures, transverters and how to use them, interpretation of Phase III telemetry, and tips for getting on Phase III inexpensively.

The arrival of Phase III promises a big increase in satellite activity, but only if you do your part in bringing newcomers up to speed. It's easy to write for *73*, and we'll pay you for your efforts. Help make satellite communications a vital and growing part of our hobby. Send today for the *73* author's guide, or send your double-spaced, typewritten manuscripts to *73: Amateur Radio's Technical Journal*, Pine St., Peterborough NH 03458.

SATELLITE QSLS

The AMSAT QSL Bureau is now operated by WB8OTH at the following address: 1850 Lisle Avenue, Obetz OH 43207. If you're on the satellites, be sure to send Perry half a dozen SASEs so that he can forward cards to you. Hundreds of cards currently are awaiting envelopes.

RS-1 AND RS-2 AGAIN

These two Soviet amateur satellites appear to be coming back to life after a long silence. If their communications transponders become operational, *73* will begin publishing orbital data on these two birds.

LETTERS

WE NEED R & D

I am an electrical engineer who has kept up with the state of the art. I know from experience that what you say about a lack of qualified engineers is not true. The lack of research and development is the problem. It doesn't do any good to train more engineers if we don't have work for them to do.

I have always been an inventor and innovator. I started by writing computer programs to design crystal filters, then worked on other systems to design TCXOs (temperature-controlled crystal oscillators—AJ). When the layoff came, I got it because R & D is the first to be cut. My design programs made me unnecessary. I then went to work for a consulting firm. We developed a crystal measurement system. We quit consulting and went into manufacturing. I had a dispute over being forced into a management position and quit. The next company got bought out by Dale and they dropped my position in engineering. This time I tried management and failed. I am a very talented R & D engineer, but I get very bored pushing papers around.

I am 41 years old, have an MSEE, have several inventions, and have 4 years graduate studies past MSEE. Motorola GED rejected me because I had too many years experience and had not moved into management yet.

I now work for a small company named Southwest Microwave. I can design anything my boss can think of. We are leaders in intrusion sensors. Two of the engineers I work with are inventors. They started Omni-Spectra by inventing the OSM microwave connector. I hope this company doesn't decide to drop R & D. I now go on sales trips and do R & D and production engineering, but my skills are sharper in R & D.

We need more than just more skilled engineers. We need R & D and management which respects and rewards engineering.

James R. Fitzsimons W7ANF
Tempe AZ

With the recently passed Rudman bill . . . which we'll have more about soon . . . there should be a lot more money for R & D. I'm sure, James, that you're familiar with the tax situation which killed most R & D. And yes, killing off R & D is as stupid a way of saving money when things get tight as cutting back on advertising, but we still see firms doing it regularly . . . shortly before going under as this response escalates the problems. But if you have been reading any of the news magazines, you also know as well as I that the need for technical people is so desperate that our colleges have virtually been cleaned out of science and electronics teachers.—Wayne.

TOUCHDOWN!

If eliminating the code from the ham exams is such a great idea, I have an equally brilliant one. Why shouldn't the National Football League shorten the length of a football field from 100 to 25 yards? In that way they could eliminate spring training (which the players dislike very much) and thus enable the ball carrier to run from one goal line to another without much effort. In a like manner, baseball diamonds, basketball courts, hockey rinks, etc., could be reduced in size. Of course, it would ruin the games, but it would make it much easier on the players, and that is the object of the exercise, isn't it?

H. B. Savage, Jr. K4MD
Coconut Creek FL

Hey, Doc . . . beautiful example of an irrelevant, emotional, non-solution to our problems, mainly a dying hobby which is desperately needed to do what it is supposed to do: set up to provide emergency communications for our country, provide a source of trained people in case of war, invent and pioneer new techniques and modes of communications . . . and foster goodwill. You know, all of those good things mentioned in 97.1, but which old-time rag-chewers seem to conveniently forget as they get further out of touch with technology and fight to keep newcomers out of the hobby.—Wayne.

BASH ADS

I have enjoyed reading *73* and I honestly believe that *73* has the best articles on building of any of the amateur publications on the market. The columns are written by hams and even though I don't have the opportunity to build all that much, I usually read and enjoy the material very much . . . it is fun just to read it.

I read most of your editorials and must admit that you certainly put forth a great deal of effort to make for interesting reading. I guess you could say that you call the shots just like you see them. This makes one not put the book down until the reading is finished.

There is one thing I'm curious about, though. In many of your editorials, you have lashed out at the publications that publish and solicit the Bash material; there have been times where you have stated that perhaps ham radio retailers should chuck the Bash books, etc. Wayne, I am not writing this letter to promote Bash material or to criticize you for the stand that you take; however, *there are 73* magazines in the past 2 years where Bash Study Guides are listed and other Bash material is advertised. I guess my question is: Are you aware of this? By the tone of your comments, I presume that you are not! I would like to get an answer that will maybe clear things up in my mind. Thank you and keep up the good work.

Larry Benham KR9M
Mt. Carmel IL

Larry, we've tried to keep the Bash cheat books out of our magazine ads, but they do creep in here and there despite good intentions. However, after seeing that not one ham in the country really gives a damn . . . I'm obviously being an idiot in trying to stage a one-man movement and should go ahead like 100% of the hams and encourage outright cheating to pass the test. Why in hell should I pass up getting a hunk of the fortune Bash is making selling ham radio down the river? If no one else gives a damn, okay, I don't either.—Wayne.

TEST INADEQUATE

I am writing this out of guilt; I just rejoined the ARRL and feel I must do something to atone for it. You have a much better magazine than *QST* and have your head in the 1980s if not the early '90s, unlike those League fuddy-duddies who are still back in the 1920s, at least in terms of outlook. However, I do expect to get a lot of use out of their QSL bureaus now that I have a real moonraker up, and *QST* does a better job of covering the regulatory scene than you. Beef up your efforts in that area, Wayne, and *73* would make *QST* look like so much QRM.

Anyway, what I really wanted to talk about is the no-code license proposal. First some background so you will know where I am coming from: I'm 52, got my first license as a Tech in May, 1979, and upgraded to Advanced in September of that year. I had followed the hobby at a considerable distance since I was a kid in high school, but

1979 was the first time that the sum of my desire plus financial ability added up to enough to go for it. I have a degree in chemistry and almost enough units in math for a major (not bragging, just backgrounding).

My first reaction to a no-code license was "Hell with 'em; let 'em sweat to learn code the way I did!" That's even though I am primarily a phone operator. Then I thought about the day I went to San Francisco for the Advanced test. I'd been warned it was heavy, very technical, and strong on SSTV. Baloney! The most technical question was where they showed a parallel-resonant LC circuit, gave the values of coil and capacitor, and asked for the frequency. That one did take awhile, but only because this fool left his calculator on the breakfast table 50 miles away and had a bit of trouble with the square root of something-or-other times 10 to the minus 15. The only SSTV question had to do with permissible frequencies, a matter which any literate person can memorize.

I have come to feel that a no-code license would be OK on at least some bands *provided* the applicant had to pass a written test that showed some knowledge of electronics beyond Ohm's Law and two-component circuits. As it stands, I have a piece of paper from the FCC that supposedly puts me in about the upper quartile of American hams, knowledge-wise, but I feel miserably inadequate when it comes to such practical matters as what to do when the rig won't work. When I think of people like my friend, Bill K5UX, who not only knows all the theory but knows when, where, and how hard to hit the damn thing with a hammer, I feel like an absolute idiot.

The no-code test should be heavy on practical things such as troubleshooting techniques and should also go into at least the basics of digital logic circuits, because that is increasingly where it's going to be. Further, the FCC should prepare enough different tests that the cheat-sheet peddlers could not frustrate the exam's intent. (In this connection, the League is worse than Dick Bash. At least Bash is honest enough to admit that he is out to cheat the system and get licenses for technical nincompoops.)

I have some other radical ideas about amateur licensing but will save them for another time, because I have run on enough for now. Again, you have the best mag in the business, so keep up the good work.

Fritz Samuels N6BLG
Vallejo CA

NEED CHEAP GEAR

Having just been able to make my first trip to the nearest ham radio store (Seattle WA) in several years, I was able to pick up a copy of *73*. I haven't read any *73*s in many years since I live out in the boonies. I also sent in for a subscription since I liked the magazine so much.

I have been a ham since 1967 and started working 2 meters when it was neat to own a Gonset 2m AM rig; what was FM? I then graduated to an old Motorola 80D and thought that was really neat. Having been away from radio for some time, I have just started thinking about buying some new gear and am appalled at some of the prices I am finding for new gear.

Working as a dispatcher at a local police department and having a family, I find that I can't afford most of the gear that I see advertised at the stores and in magazines. I realize that ham radio has never had it so good, but it really does seem that it is becoming a rich man's hobby. Who can afford a KWM380, Icom 720A, or any of the other new gear on the market? Not I! I remember that I first started with a $50 station and really had a lot of fun. I didn't work all that DX stuff, but I had fun trying.

The reason I am writing is to ask if any manufacturer or radio store makes or carries a good supply of inexpensive radio gear for us poor peons. I really like all the new gear that is on the market, but with the high price, it may as well be on the moon. I remember the old tube rigs that used to be around, but I don't seem to be able to find any of this equipment in decent condition at any of the local ham stores.

How about someone asking the big radio makers of the world to build some good equipment at an affordable price. I don't care if the radio has 10 vfo's, no-tune finals, and digital readout, but it would be nice if it didn't cost an arm and a leg.

I know that there are many articles on building equipment, but I don't have the time or knowledge to do so. There are only 4 hams in this area (none active) and parts are next to impossible to find locally. Maybe you or some of your readers have some suggestions on how the newcomer or us poor folk can get back on the air. If there are no new radios to be had, I would like to find someone who has a good stock of used equipment for sale.

I am also looking for a Tempo VHF One-Plus if any reader has one in good condition he wants to sell. I know it's a little big and doesn't have the features of the new rigs, but it is a lot easier to operate as far as I am concerned. I am interested in RTTY, FM, and satellite operation and would like to hear from those having the same problems. I am also interested in just getting back on the air and upgrading my license. I have been a Tech since 1968 and it is about time I did something!

Raymon A. Quinn WA7KGE
Forks WA

SPEAKER AVAILABLE

Your mention in the December, 1982, issue concerning noted individuals as hamfest speakers seems a very logical and clever idea. Kicking off a plan like that may be difficult, however. I would like to offer my services/abilities to interested groups. I have eight published books and over 250 published articles (all amateur-radio-related); I've presented programs in many areas of the US on topics ranging from slow scan and satellites to DXing, new gear trends, 10 FM, and QRP... plus holographic video and future communications concepts. If a hamfest/convention would like my thoughts, I would be honored to oblige.

Dave Ingram K4TWJ
Birmingham AL

AUNTIE BEEB

We greatly appreciated Roger Peterson's piece on Auntie Beeb in the January issue. We used to listen to World Service news when we lived in Berlin; also, we were happy to find out where Margaret Howard was these days. She attended Indiana University in Bloomington IN in 1969; I was fortunate enough to be in one of the same graduate school journalism courses that she was, and so we became acquainted. WD9HDZ and I last saw Margaret in London in 1975 or so and had since lost touch.

The frequency list is also much appreciated. Thanks again, and a Happy New Year.

Susie Scott N8CGM
Cincinnati OH

GENERAL CLASS ONLY

This letter was prompted by the letters that I read in the January issue of *73*. I have a few comments that I think will rile up hamdom as quickly as your comments.

First, I like the ARRL regardless of what you say and I am assuming that you get your copy of *QST* each and every month, if you will level with us. Second, I think that your opinions on *QST* are fostered by word-of-mouth interpretations of the goings on of the *QST* staff. Don't you wish that you had the income that is "wasted" by *QST*? Anyway, I subscribe to *QST*, *CQ*, and *73* because of the controversy that arises immediately after the publication of one of your tirades. Now, this letter is to create some kind of balance.

I am going on record now, and have before, as advocating a General license class *only*—no Advanced or Extra licensees from now on. Let's have the whole band for *all* amateurs and spread out for more comfort. Let's have no common denominator when we want to QSY. I also think that the different classes of licensees are creating a terrific case of class distinction and some snobbishness on calls that are completely out of line. Get rid of the different classes.

The cost of amateur gear is a constant issue with newcomers. May I say that there are terrific prices on some good used gear on the market? Don't forget, ham gear is not subject to salt and slush; 95% of ham gear is put on the market each year as a ham upgrades to the new gear for the fast electronic improvements that seem to be running away with us. Does anyone remember the $500 and $600 cost of Golden Eagles and Trams and the big Johnsons—5 Watts instead of 100 out?

The last of my comments is about the indiscriminate use of linears. What a band 20 meters would be if all the linears were shut off for 1 week on a trial basis. If linears had a built-in splatter guard and would shut down immediately if overdriven, it would be great and the band would be operable. My contention is that linears beget linears and the only things the guys want to hear are 40 over nine reports, regardless of audio clarity or bandwidth.

I am one of the "older" hams and like to feel that we are the stabilizing factor in good conduct. The younger ones with their so-called new ideas and limited resources are in no position to dictate on hamming until they get enough air time to make it count. The young fellows do very well as long as they use good common sense in their operating practices, and we do need them.

About home brew—outside of small projects, this is fine, but just try to design or even build anything to match what is on the market today, with its phase-locked-loop circuits and terrific engineering. Yes, the fun is in getting it to work, but I'll bet that is as far as it goes.

Jack Golden KK2W
Portville NY

Jack, many hams like the ARRL. After being a member for over 40 years I don't like 'em... and I don't dislike 'em... any more than I like or dislike a lot of other bureaucrats. And, yes, I do draw conclusions about what is going on at the ARRL from things insiders tell me... something wrong with that? Perhaps it is a frugal Yankee background which makes me dislike seeing money wasted... and remember that I am an ARRL member and presumably thus have a vested interest in getting the best for my investment. Your one-class idea isn't new or novel, but does have much to recommend it. I've written editorials suggesting just such a licensing arrangement. Ham-gear costs? If you put the cost of a new rig into any perspective it has to be one of the best hobby investments in the world. I can buy a darned good allband rig for about the same price as a wind surfer, a good camera, a twentieth the cost of a good sports car, a good typewriter, a computer, less than a good hi-fi, less than a good TV set, and so on. Put things into perspective. Only hams who are not progressing and using their hard earned skills are short of money. The world is anxious to pay almost anything for repairs of electronic equipment, help in setting up security electronics, and many things for which a good ham is eminently qualified, even in his spare time. And now, linears on 20m... yes, the band would be a lot quieter without 'em... and the hams in Asia wouldn't hear many US stations much of the time. I suspect we would still have plenty of interference, but just a couple of S-units weaker.—Wayne.

LEGALIZE MDS

I have an idea. I don't know if it is new, but it might help overturn some of the recent court rulings against owners of "illegal" MDS receivers.

Install 450-to-2300 ATV repeaters. We have the 2300-2450 band and it can be used for ATV. It also can be tuned very easily by any of the MDS receivers on the market. Besides stirring up activity on this band, it would permit clubs or individuals to "broadcast" CW or training classes or even official bulletins. I think this is just as legal as W1AW and it would give anyone a reason for owning an MDS receiver. After all, you don't have to be licensed to own a shortwave receiver.

Maybe some of the 2-meter FM pioneers that are looking for some new challenges can do this. The technology is simple and I think somebody is already marketing a low-cost 2300-MHz transmitter.

With such a system in place, it ought to be damn easy to get these outrageous rulings overturned. If we don't do something now, cases like these involving our personal freedom are only going to get worse.

Fred Studenberg W4BF
Melbourne FL

BIG-FOOT GRINGO

So, Wayne, you and your wife survived an odyssey through Colombia and the "barracudas" who besieged you at the street corners that serve as terminals for inter-city buses in Barranquilla and Cartagena!

I have been to the same corners looking for the same bus services as you did and fully agree with you regarding the inexcusable conditions at and around those spots. However, I must address and comment on some of the other concepts expressed by you:

1) *Poverty*—Yes, Colombia is poor. However, not all of it is in disrepair. Inexcusable, too, and for that matter even more so, is the heartbreaking squalor in some areas of New York City, Boston, New Orleans, and Appalachia in this, the richest country of the world.

2) *The "Barracudas"*—This type is found almost everywhere, not only in the so-called Third World. At least in Barranquilla and Cartagena those poor people were eagerly trying to make a buck by rendering some service and were friendly. A great number of the poor in the USA try to make a buck by staying on welfare. And, how about the "friendly" muggers, pimps, and prostitutes that teem in New York's Times Square and

in Hollywood, California? They are "barracudas" of a worse kind.

3) *The Buses*—For a USA world traveller of your kind (if it's Tuesday this must be Belgium), loaded with Yankee gold, you chose the cheapest mode of transportation. Didn't it dawn on you to check if a private, air-conditioned limousine was available? It could have been. I travelled by bus, for my interests and values are different from yours, of course.

4) *The Language*—In trying to be smart, your subconscious betrays you and your biases surface all too clear. In the Caribbean area, old man, there are millions of black people. For your education, Spanish, not Swahili, is the language spoken by Colombians of the black race. I wonder if you have travelled within the USA. In case you will ever travel through Washington, DC, Alabama, Louisiana, the Carolinas, Virginia, New York, etc., don't be surprised if the blacks in those areas do not speak Swahili but English.

5) *Amenities*—Ah, there was an ice machine on your floor at the hotel in Cartagena! Had you asked for it, you could also have had ketchup to go with your steak!

Old Man, it seems that the *73* publication has in you an editorialist who travels and sees the world and writes about it with the sensibility of the typical big-foot gringo oblivious of the fact that the USA, for all its might and glory, also has many an eyesore, both physical and of the soul, that can be easily exposed.

And what is even more pathetic, you visited Cartagena, which is, so to speak, a banquet in history and Spanish colonial architecture, and you missed it all, it seems, since you found nothing loftier to comment on than a street corner and an ice machine in your hotel. What an input for your readers; what a shame!

The foregoing may be an overreaction, but I hope that it will at least serve for you to understand and learn that writing about other countries and peoples requires much tact and responsibility. I dare you to give this letter equal time in your columns. Long live *QST*!

Alvaro Guzman WA6WMN
Arleta CA

Alvaro, you seem to have your own problems. I enjoyed Colombia and most of the readers enjoyed reading about my short visit there. I'm sure there is some rationale for publishing your letter, but other than to present a distorted view of what I wrote, I'm not sure what it is.—Wayne.

FUN!

THE YEAR THAT WAS—1964

Do you know what the Wireless Operators Memorial is? No, it's not a monument dedicated to those who died while waiting to make a contact off of a DX list. If you're ever in New York, you might want to make a trip to Battery Park to view one of the Big Apple's least-visited tourist attractions. A granite column with bronze plaques listing the names of 48 radio operators who went down with their ships while faithfully sending out distress signals, the monument was installed by a group called the Veteran Wireless Operators Association. If you have trouble finding the memorial, just remember that it's about halfway between a bust of John Wolfe Ambrose, known for his 40-year struggle to fulfill his lifelong dream of dredging New York Harbor, and a statue of John Ericsson, holding what looks like a scrub brush but is actually a scale model of his ironclad Civil War ship, the *Monitor*. Remember, you read about all of this in FUN!

Let's move on to more esoteric items. The other day, I was browsing through the on-line encyclopedia that's available on the Dow Jones News/Retrieval Service. Suddenly, I thought, "Gee, I wonder if they have anything on my favorite ham, Hiram Percy Maxim?" With that, I typed HPM's name into my TRS-80 and got the information that he invented the gun silencer, co-founded the American Radio Relay League, and did pioneering work on the automobile muffler. Nothing new there. What I did find fascinating, however, was Maxim's bibliography. According to DJNS, one of the primary sources of information about old Hiram is a nifty tome titled *Merchants of Death* (1934), edited by Clifton Johnson. Golly. The ARRL co-founded by a "merchant of death"? Something to think about.

Before we get to the puzzles, a few words about this month's topic. With this installment of FUN! we inaugurate a new feature—"The Year That Was." On an irregular basis, we'll be looking at specific years in ham-radio history; years that for one reason or another (usually several reasons) turned out to be pivotal times for our hobby. To kick off the series, we start with a look at 1964. Why 1964? Well, it really was a turning point in ham radio. Phone ops were finally making the big shift from AM to SSB in droves, the great incentive licensing debate was at a peak, and the ARRL was celebrating its 50th anniversary. On a more personal note, 1964 was the year I first came in contact with amateur radio. It happened at the 1964 New York World's Fair. The League had installed a station at one of the pavilions and was inviting the public to get a first-hand look at our hobby. I asked if I could twist the dials on one of the Collins rigs and was told—quite rudely, I remember—no. I later found out that the fellow who denied me access to the radio later became president of the ARRL. Psychologists, take note; I was 8 years old at the time.

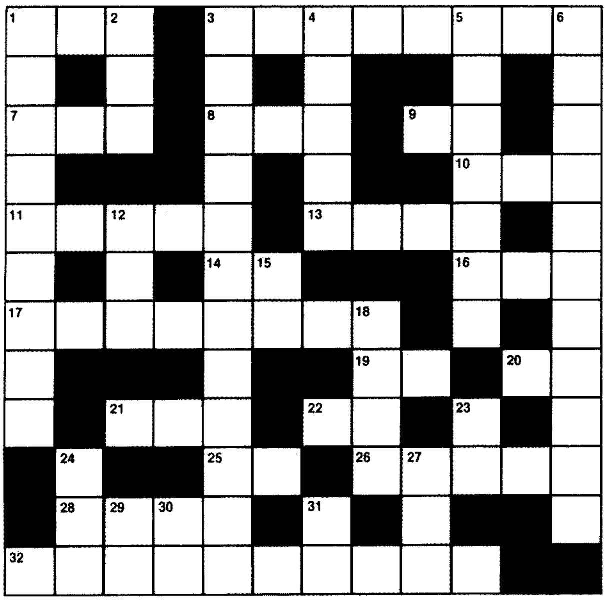

Illustration 1.

ELEMENT 1—CROSSWORD PUZZLE (Illustration 1)

Across

1) Ham slang for something nice
3) Lyndon . . .
7) Not 1 Down (abbr.)
8) World's radio board (abbr.)
9) Spain prefix
10) Month of ARRL's anniversary
11) Our globe
13) Little of this on 20 meters
14) Plate current
16) A personal listening apparatus
17) A primary goal of our service
19) Western city (abbr.)
20) Line power (abbr.)
21) Top DX frequency (abbr.)
22) Egypt prefix
25) An international organization (abbr.)
26) AC4-land
28) Threadbare
32) Big 1964-65 event (2 words)

Down

1) Ham who ran for president in 1964
2) Make a tape copy
3) Although HQ was built in 1962, ARRL still had this in 1964 (2 words)
4) Bird #3 was built in 1964
5) Where many jammers should be living
6) Site of 32 Across (3 words)
12) African broadcast company (abbr.)
15) The value of . . .
18) Abundance
23) Decibel (abbr.)
24) VHF band where activity was mostly AM in '64
27) Morse question mark
29) Digital gate
30) Radiolocation (abbr.)
31) Direction finding (abbr.)

ELEMENT 2—MULTIPLE CHOICE

1) As mentioned during the introduction, the ARRL had a ham station at the 1964 New York World's Fair. Pick the company that housed the station in their pavilion.
   1) Pepsi-Cola
   2) 7 Up
   3) Dr. Pepper
   4) Coca-Cola

Illustration 2.

2) The son of which former president of the United States was president of the ARRL in 1964?
   1) Woodrow Wilson
   2) Herbert Hoover
   3) Franklin Roosevelt
   4) Warren Harding

3) What city played host to the 1964 ARRL National Convention?
   1) Des Moines, Iowa
   2) Lincoln, Nebraska
   3) Independence, Missouri
   4) New York, New York

4) Amateur radio played a vital role (some say it was ham radio's finest hour) during this 1964 earthquake. Pick the disaster's location.
   1) California
   2) Mexico
   3) Chile
   4) Alaska

5) During 1964, the FCC began charging amateur radio license fees. How much did it cost back then to take an examination or renew a ticket?
   1) $2.00
   2) $4.00
   3) $10.00
   4) $20.00

ELEMENT 3—TRUE-FALSE

	True	False
1) The callsign of the ARRL's fair station was K2WF.	___	___
2) By 1964, more than 6000 hams had responded to the FCC about the incentive licensing proposal.	___	___
3) The first-ever Field Day was held in 1964.	___	___
4) The 1964 "Goldwater Bill" provided for reciprocal operating agreements for amateurs.	___	___
5) It cost $20.00 to request a special callsign in 1964.	___	___
6) The FCC celebrated its 30th anniversary during 1964.	___	___
7) The US Government celebrated the ARRL's 50th anniversary by issuing a commemorative medallion.	___	___
8) In June, 1964, the FCC temporarily outlawed the use of semiautomatic keyers ("bugs").	___	___
9) 1964 was the peak of a solar cycle.	___	___
10) As a feature of its anniversary year, the ARRL sponsored a contest in which selected articles submitted to *QST* were awarded a $25 US Savings Bond.	___	___

ELEMENT 4—HIDDEN WORDS (Illustration 2)

Hidden in this puzzle are the names of ten amateur equipment manufacturers active during the year 1964. The names are formed in any direction—horizontally, vertically, or diagonally, forwards or backwards. As you find each word, circle it.

THE ANSWERS

Element 1:
See Illustration 1A.

Element 2:
1—4 Coke was it.
2—2 Herbert Hoover, Jr. W6ZH.
3—4 New York, New York. The town so nice they named it twice.
4—4 The famous "Good Friday" quake.
5—2 See? Not everything has gone up in price!

Element 3:
1—False K2US.
2—True No apathy then.
3—False Long-time tradition.
4—True Help for the traveling ham.
5—True Let's see. For a 1 × 2 call that was five bucks a character. Not bad.
6—True Didn't you ever hear of the Communications Act of 1934?
7—False A postage stamp.
8—False Come on!
9—False No. But things were looking up.
10—True Look, it's more than they pay now.

Element 4:
See Illustration 2A.

SCORING

Element 1:
Twenty-five points for the completed puzzle or ½ point for each question correctly answered.

Element 2:
Five points for each correct answer.

Element 3:
Two and one-half points for each correct answer.

Element 4:
Twenty-five points for the completed puzzle or two and one-half points for each name found.

Know your nostalgia?

1-20 points—Born in 1965
21-40 points—Amnesia victim
41-60 points—Out of the country during '64
61-80 points—Remembers it well
81-100+ points—Photographic memory

REVIEW

LARSEN MOBILE MOUNT

Before I left my parents' home to go into the great wide world, my father took me by his side and offered sage advice from his years of experience.

"Son," he said, "never leave your mobile rig in the car overnight, or it will be stolen."

For years, I have followed his advice faithfully, disconnecting power leads, coax, and auxiliary speaker connections, fighting with jury-rig mounts made from rubber bands and plywood that substituted for a good, permanent installation. Though this nightly ritual quickly grew tiresome, it was not until recently that I discovered a different way that takes no time and little effort—the Larsen Quik-Change mounting system.

The Larsen mount comes in two pieces—one which is mounted in the car, with all of the connections permanently hooked up, and a lower half which is installed on the radio. A second set of permanent connections are made here, and the two halves slide together, completing the circuits and securely holding the radio.

Connections between the two halves are made via 4 pins and a specially-designed coax connector. All of the pin connections create a good electrical contact; I have had no interruptions due to poor contacts, although the unit has been tested over a period of several months, including driving on dirt roads with ruts that would dwarf the Grand Canyon.

Nor has the mount shaken loose. Larsen thoughtfully equipped the Quik-Change system with a plethora of mounting holes on the half which stays in the car. This makes it easy to install the unit across a wide range of automobile makes and models. The top half is composed of an impact-resistant plastic slide topped by a metal plate. Out of the back comes a short length of RG-58/U which ends in a female threaded coax connector; all other connections are made to a terminal located between the top plate and the lower plastic piece. When installing the mount, you must first make all of your connections, close the two pieces, then mount the top half under the dash or in another suitable place. If you pay attention to the routing of your wires and cables, once the top half has been secured, only about 3/4" of black plastic will show beneath the dash.

The bottom half sits on top of your radio like a saddle and is held in place by the standard side mounting holes. The width of the radio may vary from as narrow as the mount itself to about 9" wide. Again, all leads coming from the radio, with the exception of the antenna, are connected to a terminal on the back of the mount. Two leads come from the mount—a piece of coax and a connector which screws onto your radio's SO-239, and a dual-conductor wire which ends in a subminiature phono plug. This plug is for your radio's external speaker jack, and through the top half of the mount, it can be wired into any speaker configuration you desire.

Making the basic connections—power and antenna—do not use up all of the connecting pins, so this system leaves room for expansion if you want to add on any special features.

In use, the Larsen system has proved to be a boon to my mobile operating. When making a trip with frequent, short stops, it takes only seconds to pull the radio from the mount and swing it into the trunk. On my return, I slide the radio back into the mount, and it fastens with a satisfying click. The release mechanism has been designed for easy, one-hand operation so you can pull the radio and carry it without having to change your grip.

However, the advantages of the Larsen system don't stop there. If, like many hams, you own two cars and frequently find yourself driving the one without your rig, two Larsen mounts will solve the problem. With them, you can move your rig from one car to the other with ease. Or, if you have two rigs—for example, a 2-meter FM and a converted 10-meter rig—you can use the Larsen system in conjunction with a coaxial switch to easily change from one mobile rig to another.

The low profile and black plastic make the Larsen mount difficult to see once it is installed, and it will not interfere with passenger comfort in smaller automobiles. It has also been designed to be manufacturer-independent and will work equally well with almost all brands of radios.

Larsen also provides an optional key lock system which will lock the two halves together. That may be satisfactory for short hops, but this mounting system makes it so easy to remove the radio that there is no excuse for allowing your rig to become a sitting duck.

For additional information, contact *Larsen Electronics, Inc., 11611 NE 50th Ave., PO Box 1799, Vancouver WA 98668; (206)-573-2722.* Reader Service number 477.

The Larsen Quik-Change mounting system.

RTTY AND MORSE FROM KANTRONICS AND COMMODORE

Computerized RTTY and Morse have been technically possible for a long time. Unfortunately, "technically possible" too often translates into "complex and expensive." Consequently, the number of amateurs enjoying this interesting mode remained, until recently, relatively small. The advent of low-cost microcomputers was bound to change that situation. Enter the Commodore VIC-20, the Kantronics Hamsoft communications software, and The Interface terminal unit (TU), also from Kantronics.

A Three-Part System

In addition to your station transceiver, there are three main components to a computerized amateur communications system: a computer, software which causes the computer to behave as a communications terminal, and interface hardware to connect the computer to the transceiver. Let's examine each item.

The VIC-20 is an extremely popular computer. According to its manufacturer, several hundred thousand VICs are now in the field. For amateur radio use, this computer has two advantages. First, the VIC possesses a full-size keyboard; many other low-cost computers do not. A real keyboard is a must for comfortable typing, and believe me, you'll be doing a lot of typing when you get hooked on RTTY. A second reason for choosing the VIC is the Kantronics hardware and software, which is designed specifically for use with the VIC-20. This feature greatly simplifies the task of getting on the air. The retail price of the VIC is $299.95, but it is often discounted to well under $200.

A computer without software is like a stereo system without records—useless. Kantronics' Hamsoft program enables the VIC-20 to function as a communications terminal for RTTY and Morse transmission and reception. Such a terminal is sometimes called a "glass teletype" with some justification. Together, the computer and software comprise a substitute for a mechanical teleprinter, such as the venerable Model 15. The main disadvantage of the mechanical method is that the speed, mode, and other operating parameters are fixed. Changing speeds, for instance, requires changing parts inside the machine. By contrast, changing speeds in a computer-based system can be as simple as pushing a button. Switching from Baudot to ASCII or Morse is equally simple. Try that on your Model 15! Flexibility—that's the main advantage of going to a computer. This flexibility is illustrated by Table 1, which lists the features of the Hamsoft program.

Incidentally, Hamsoft is supplied, not on cassette tape or floppy disk, but as a small circuit board that plugs into the game cartridge slot of the VIC-20. The program resides in a read-only memory (ROM) on the board—very convenient. Hamsoft for the VIC-20 is priced at $49.50. The program is also available for the Apple II, the TRS-80 Color Computer, and the Atari 400 and 800.

Although Hamsoft may work with many different terminal units, Kantronics warrants it to perform correctly only with The Interface, Kantronics' own TU. The Interface is a small plastic box full of hardware that goes between the terminal (the computer) and your transceiver. It measures just 5" × 2.5" × 5.25". Under control of the Hamsoft program, The Interface keys your rig, converts received audio into TTL levels that the computer can accept, and converts computer-generated TTL levels into audio tones for RTTY transmission or into on-off keying for CW. The rear panel of The Interface is loaded with jacks for connection to the transceiver and computer. The front panel contains the power switch, a RTTY/CW selector, an LED tuning eye, and a 10-segment LED bar-graph tuning aid. The Interface contains active filters for both RTTY and CW. The Interface retails for $189.95.

Connections

Putting it all together is mainly a matter of wiring cables to connect your station transceiver to The Interface. Kantronics provides plugs to fit the jacks on the rear of The Interface, but you must supply connectors for your transceiver's mike, CW key, and external speaker jacks. The VIC-20/Hamsoft/Interface hookup requires five cables.

Using the System

With this system, the VIC-20 executes the Hamsoft program as soon as you turn the computer on. When all parts of the system are powered up, a short series of questions appear on the VIC's video display, allowing you to tell Hamsoft what type of terminal unit you are using, select a mode, enter a message into one of 10 buffers, or set the internal clock. If you select RTTY, the system goes directly into the 60-word-per-minute (wpm) Baudot mode. From there, however, you can choose other speeds and modes (ASCII and Morse) with a few simple keystrokes. The system is not quite as easy to use as some others, but once learned, works fine.

At this point, it's time to tune in a signal and see what prints on the video display. The tuning eye and bar graph on The Interface are valuable aids here, but it still requires careful tuning to get good copy. I found the best results when I followed the Kantronics tuning procedure. This involves beginning the tuning with the signal at a low pitch, then slowly increasing the pitch of the signal until the tuning indicators respond and good copy shows on the video display. It works that way most of the time, but there are the inevitable exceptions. Sometimes I tried several speeds before finding the correct one. At other times,

Morse Code
- 5-99 words per minute
- automatic speed tracking

RTTY
- Baudot: 60, 67, 75, 100 wpm
- ASCII: 100, 300 baud
- automatic CW ID

General
- split screen display
- 1024-character transmit buffer
- 10 255-character message buffers
- printer compatibility for hard copy

Table 1. Features of the Hamsoft RTTY/CW software.

copy was possible only by switching to the opposite sideband on the transceiver's mode switch. Of course, there were some instances where the filters in The Interface were not selective enough to separate two closely spaced signals.

I was disappointed in the manuals for the Kantronics products; neither was very well organized. In addition, the Hamsoft instructions were much too brief, lacking even one example of how to use the system. Examples are absolutely essential, especially for newcomers.

Conclusions

Buying a computer for RTTY and CW may seem like a big investment. It's important to remember, however, that that same microcomputer is also available for myriad other uses, limited only by your imagination. In addition, some ham dealers offer a low package price when you purchase the computer, software, and interface at the same time.

I have used the system for many successful contacts on both RTTY and CW, including DX CW QSOs and local 300-baud ASCII contacts. In comparison with other computerized CW/RTTY setups I've used (all more expensive than this one), the overall performance of the Commodore/Kantronics combo rates better than average on CW, a bit below average on RTTY. On a price/performance basis, however, the VIC-20, the Hamsoft program, and The Interface are hard to beat.

For more information, contact *Kantronics, 1202 E. 23rd, Lawrence KS 66044; Commodore International, 487 Devon Park Drive, Wayne PA 19087.* Reader Service number 488.

FIST FIGHTER

Think you're a pretty good CW man, eh? How are you with a hand key? Do those B's and V's leave a little to be desired? What about F's and Y's? Well, maybe you are pretty good at that, but I'll bet you that this little gem from the Blacksburg Group can make you better!

The boys at Blacksburg figured that you *can* teach an old dog new tricks, and it's even easier to teach a young dog new tricks, so they came up with a neat idea for creating the kind of fist you've always wished you could have. They designed a circuit that would have a built-in memory for perfectly-formed characters at any speed. They also programmed it so that the proper space between characters would be remembered. Now comes the neat part: Fist Fighter doesn't send code—you do, but it forces you to send it in accordance with the built-in memory. If your fist tries to do its own broken rhythm and jagged little dance on the key, you're in for a big surprise—nothing comes out of the box!

Well, you say, you can get around that easy enough by fooling the circuit, right? Nope, won't work. The only way you're going to fool the circuit is to send CW the way it wants you to send CW, not the way you want to. Dad-blamed thing is frustrating, believe me. First time I tried it, I got mad and left it in frustration and anger. No danged machine is gonna tell *me* how to send code, nossir.

I came back and tried setting it to different speeds . . . must be some speed I could have my way with it. Wrong again! More anger and frustration. Well, I did get even with the little critter in the end (heh,heh). I plugged it into the power supply with reversed polarity! Served the little demon right!

Well, I sent it back to the Blacksburg boys, and they fixed it . . . for good. They changed the circuit a bit and made it so that no matter which polarity you use when you connect it to your little 12-volt-dc supply, you won't hurt it.

Round three. At last, I was beginning to get the hang of it. So that's the way a Y oughta sound? Hmmm . . . lemme see, now a O. Not bad. That little machine is learning from me after all, says I, soothing my own ego a bit. Might not have to throw it out, after all!

Round four. Showed the little jewel to my buddy, Ken, who is learning to become a ham. He's been working on the code right along. Boy, bet this will fool him! Here, Ken, try this little machine . . . see if you can make it work. (Boy, this is gonna be fun, thought I . . . let's watch him sweat like I did.)

What's that—code, nice and easy and regular coming out? Can't be! Well, so as not to bore you any more, I'll make it short. That little Fist Fighter got along just fine with Ken; they *both* had nice fists.

Later, I said to Ken, "How do you figger that. Ol' Buddy? How come you can make that little rascal sit up and beg, while it just sits there and fights me? Heck, I been CWin' for 32 years and you haven't been CWin' for 32 hours yet!"

Well, Ken kinda sat back and smiled and said so quietly I could barely hear him; "Well, Jim, maybe you just have more to unlearn than I do."

Now, I'm not going to say that the Fist Fighter is for everybody, because it isn't! If you've got a short fuse and you hate to learn new tricks, stay away from it, because you're not going to get along. On the other hand, if you are willing to improve yourself or if you're just starting out and want to learn to send some of that machine-perfect code with a hand key, stick with the Fist Fighter. It's a better teacher than most, because you teach yourself. A little patience and discipline is all you need. Feller like myself, of course, goes back to his old ways and his friends say, "There's Ol' Jim . . . always can recognize that fist of his!"

If you want a little workout and think you're a better fighter than the Fist Fighter, why don't you prove it by sending your $59.95 to the boys in Ol' Virginny? Write *Blacksburg Group, Box 242, Blacksburg VA 24060, (703)-951-9030.* Reader Service number 476.

GALFO'S APPLE II AMATEUR RADIO COMMUNICATIONS PACKAGE

Without a doubt, the computer has entered into the amateur radio shack to perform a wide variety of functions. Perhaps one of the most established and growing areas involves RTTY communications. Mr. Galfo has provided the amateur community with a fine software package for RTTY, Morse, and ASCII purposes. The inexpensive software provides a flexible medium for communications and is very simple to operate. The Amateur Radio Communications Package for the Apple II computer is a versatile one indeed. It provides for transmission and reception of Morse, Baudot, or ASCII codes. The speed range is variable with buffering and memory capacity which is quite large.

The Morse portion of the program provides for transmitting rates between 2 and 125 words per minute. The speed which is selected for transmission also selects the optimum receiving speed. The actual speed of reception will adapt to within a 3 to 1 range of the sending speed. The dot to dash radio is set up at 1 to 3 with character and word spacing also included. The RTTY and ASCII portion uses the 5-bit Baudot or 8-bit ASCII codes with a continuous speed range of 32 to 300 baud. The usual control characters are quite easily accessed. Transmit/receive switching is available from the keyboard (ESC) or from the software (control C). Morse characters such as end of message, end of QSO, end of work, go ahead, end of line, wait, and break are included. CW ID followed by a carriage return, line feed, and letter sequences are also available with one command. An interesting feature involves an end of text marker in the transmit buffer. When this signal is encountered in the text, the transmission is terminated, followed by CW ID. One is then ready to receive or continue the same or another memory.

The program's *transmit buffer is large.* For an 8K Apple, there are 500 bytes available; for a 48K Apple, there are 20.5 kilobytes available for the transmit buffer. With the use of the end of text marker in the transmission buffer, this allows for extended type ahead usage. The stored message texts range from 2 kilobytes in the 8K Apple to 22 kilobytes in the 48K Apple.

The message text can be formatted in a variety of ways but basically consists of using a key word in the text to bring up any one of a variety of messages which can be created and entered into the software program itself.

One example is typing into the buffer "okay, control A TNX control A." The output would be transmitted as "okay, thanks for the call" provided that you had previously entered the key word and message into memory. For those individuals not familiar with programming, it only involves two steps to create a memory such as this:

```
DIM TNX $ (20)
TNX $ = "thanks for the call"
```

There is a 255-character limit in each message memory. In using the key words, one only needs to enter "control A" before and after the key word to identify it as a key word for memory recognition. With 22,000 bits of information available for message storage, one can readily see the flexibility of having a wide variety of subjects covered for use without having to resort to changing programs, whether it be contesting, DXing, or rag-chewing with the usual crowd. The ID key word is specific in that it will send the proper Morse identification prior to the receive mode.

The type of receiver, transmitter, transceiver, terminal unit, frequency shift key circuit, and CW threshold detector are all independent of the program. A simple and reliable schematic is available with the software ("Got an Apple? Want RTTY?", Constantine Papas, *73*, October, 1982). One or two evenings should normally be more than adequate to build and interconnect the Apple II computer with the terminal unit, transmitter, and receiver. A store-bought terminal unit with AFSK only takes a few minutes to plug in.

The program itself is in two parts. A set of machine-language routines handles the real-time task and code conversions, while Basic is used to execute the conversion between user and computer. The software is available from tape or diskette. The diskette programs are always more easily used, but even loading the program from cassette is quick and non-traumatic. After loading the program, the package is set into motion by entering "run" as a basic command. Buffer and memory allocations are automatically set according to the memory space available. The program begins by requesting several types of information, basically whether or not one is to use Morse, Baudot, or ASCII. The word or character mode is determined next. When in the word mode, the transmitter will not transmit the last word until it is complete and a space has been typed. In the character mode, each character is sent and is released from the text buffer one by one. The transmission speed is determined next. The 2- to 125-word-per-minute Morse and 32- to 300-baud RTTY speeds are all available. A fill character is requested, should the transmit buffer empty; one or two non-printable characters or no characters at all may be chosen, in which case a steady mark is maintained when the buffer is empty.

Following the initial setup, the program will go into its receive mode to copy signals present on the input line. The screen is now divided into three separate fields. The top 16 lines are the received text. A single center field is the field showing the character being sent, as well as the next 38 characters to follow. The last five lines on the bottom of the screen show the text that is being placed into the transmit buffer. The fields grow individually as text is added to each. Word wraparound is automatically adjusted for a 40-character line on receive.

When ready to transmit, the escape key will allow you to toggle between transmit and receive. Entry into the transmit buffer may be made during transmit or receive from the keyboard. If the transmitter buffer empties, the characters will stop until you once again enter information to be transmitted. The escape key may be used to return the state to receive or, at the end of a transmission, one may enter a "control C." When the "control C" is encountered, the program will go into its receive mode automatically following a CW ID.

The text you prepare does not require carriage returns or line feeds. They are generated automatically to give a standard 72-character line that does not split short words when operating RTTY. The carriage return, line feed, letter sequence is placed at the beginning of each transmission automatically. CW transmission is a continuous stream, as one would normally find. Character spacing is three dots with word spacing of five dots on transmit.

Another item included in the software is

HAMEG OSCILLOSCOPE

● 20 MHz Dual Trace
● Built-in Component Tester
● X-Y Operation (1:1 Ratio)
● 2 x 20 MHz, Max. 2 mV/cm
● Timebase 40 ns ~ 0.2 s/cm
● Trigger Bandwidth 30 Mhz

✓133 Rivendell Assoc.
RFD-5 DERRY, N.H. 03038 WARNER HILL (603) 434-5371

✓See List of Advertisers on page 114

"control B" which clears the text buffer, clears the entire screen, and returns the system to the receive mode. With the ability to use the forward and backspace cursor movements, modifications can be easily made to the transmit text prior to it being transmitted. Should a speed change be required, a simple "control S" returns the system to the interactive mode for a speed change or other control change.

All interconnections to the Apple computer are made through the game port. The RTTY input signal, RTTY output signal, Morse input signal, transmit/receive control, and Morse output signal are the only five connections other than a common ground required.

There are no provisions for received message storage or the ability to print out the received text. There is also no provision for "WRU" (who are you?). It is quite simple to load the program, answer a few questions, and begin receiving or transmitting. The combination of simultaneous reception with the ability to use the extensive buffer and memory storage space makes for a relaxed communication program, providing an enjoyable means of operating.

The Rest of Ham Radio
Dan Fox W2IQD

Foundation Publishing
PO Box 805
Merrimack NH 03054
173 pages, $13.95

The generic fad has overtaken amateur radio. We have generic callbooks and logs. Who knows, before the year is out someone may introduce a generic rig. It will come in a white cardboard box and bear the label "Transceiver." With this in mind, I was not surprised to find a generic operating manual in my mailbox. But once you look beyond *The Rest of Ham Radio*'s plain wrapper, you'll be pleasantly surprised by its contents.

Readers familiar with Dan Fox W2IQD's earlier effort, *The Apartment Dweller's Handbook*, can attest to his ability to get to the heart of a subject and present practical solutions to everyday problems. In *The Apartment Dweller's Handbook* it was solving the problem of limited resources, whether it be money, room for antennas, or ways to beat TVI. Now, with the task of assembling a station out of the way, W2IQD focuses quite literally on "the rest of ham radio." Acknowledging that newcomers to ham radio have plenty of literature to get them through their first QSOs and that old-timers probably don't need a new book, *The Rest of Ham Radio* is aimed at the advanced beginner.

Two chapters are devoted to DX, another two cover contest operation, there is a section on awards, a chapter on repeaters, and so on. Pastimes like QRP operation, satellites, RTTY, and SSTV are the final four chapters. Purists may criticize the lack of coverage of such topics as hang-gliding mobile or coherent CW, but the author, wisely remembering that a book cannot be all things to all people, decided to stick to amateur radio's most popular haunts.

Unlike many of amateur radio's traditional tomes, *The Rest of Ham Radio* doesn't rest on an ivory tower view of what the author thinks amateur radio should be. Instead, W2IQD combines his twenty-five years of operating experience with advice from acknowledged experts and a lot of research. The book that results is a lot like a smorgasbord: You might not like everything that is offered, but you're sure to find something that will satisfy your appetite. And if the information on such subjects as satellite operation or SSTV doesn't appeal today, then it might next year.

Perhaps it is nitpicking, but I was just a tad uncomfortable about paying $13.95 for a book that has a homemade appearance. After realizing that everything costs more these days and that you really can't judge a book by its cover or the typewriter-style print and amateurish drawings, I've concluded that we need more books like *The Rest of Ham Radio*. In remembering the experienced beginner or General/Technician class licensee just starting out, W2IQD has given the "forgotten ham" something to cheer about.

The Rest of Ham Radio is distributed by *Birch Hill Sales, PO Box 234, Peterborough NH 03458.* Reader Service number 487.

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

I promised a tip of the hat to Al Jolson last month, so here we go. Though April showers bring May flowers, the columnist's mailman brings letters, and do we have a bunch this month!

Let's start with a topic I don't think we have touched upon ever in this column. Francis Surovec WD9HPA of Fort Wayne, Indiana, writes that he is using a "clean" Teletype® Model 28 in his RTTY station, but would like to quiet it down. He lives on the second floor of a duplex, and despite the open-mindedness of his neighbor, he is still concerned about the amount of noise, particularly the hum of the running motor.

Well, when I lived in an apartment (also on the second floor) with a Model 15, I faced much the same problem. I remember the day that a new family moved in downstairs and the man of the house came upstairs to see us. It seems that he was an old Navy communications man and "could have sworn he heard a Teletype machine," but couldn't believe his ears. When he saw the Model 15 in my bedroom, well, you can imagine his face. The racks of old equipment didn't hurt, either. Nonetheless, I did what I could to soundproof the machine, and here are a few tips.

Go to a well-stocked hardware store and look for a "fatigue mat." These are thick (one to two cm), dense foam mats that are used at counters for people to stand on. Cut one to size and use it *between* the machine and table, if possible. Another mat may be used under the table, between legs and floor. Building an acoustic enclosure of lumber and lining it with ceiling tile also helps to cut down on transmitted kerchunking. You can often get slightly damaged two-by-four-foot ceiling tiles for the asking at building supply houses. They are ideal to line such a cabinet. Finally, experiment with where in the room you put the machine. Random resonance in the floor may magnify the sound quite a bit in one area, attenuate it to almost nothing a few inches away. It's kind of like swr! Try these ideas out and let me know what happens.

Regards to another medical colleague, Dr. G. Bescher F6ADX, from Plerin, France. His letter relates his use of a TRS-80 for both computing and amateur radio and the acquisition of a Dataproduct T-1602 printer. He is in need of technical information for this printer. Anyone with a manual or such can write to him at 64 Rue du Roselier, Plerin, France 22190. I'm sure he would appreciate the help.

Richard Flink WB2SOU in Hillsdale, New Jersey, is another individual looking for frequencies of commercial stations broadcasting with RTTY. We have described several sources for such information here in the past; I just found another! Now this is going to get a bit off the track, but bear with me.

Universal Software Systems, Inc., has put together a RTTY program for the Apple II computer. Called "Super-RATT," this combination of machine language and Basic sends, receives, saves to disk, or sends from disk on an Apple II and almost any demodulator. It is user-modifiable and may be backed up or copied for personal use without problems. RTTY is supported at all common speeds, and CW from five to 100 words per minute. Several unique features include the ability to decode bit-inversion ciphers, such as used in various press signals, a file transfer system for interstation exchange of data, and video or hard-copy output. As if that is not enough, a full Radio Bulletin Board system is built into the software, allowing your computer to become a central focus in a communications system.

As part of the ongoing support for users of Super-RATT, USS is publishing a newsletter, *The RATT's Nest*. In its premier issue, a listing of RTTY press stations logged by users is given. Also included is news of new products and updates, as well as user modifications passed along but not guaranteed by the management. Looks like a nice package, available from Universal Software Systems, Inc., 9 Shield's Land, Ridgefield CT 06877. Be sure to tell them RTTY Loop sent ya! As I said, the story was a bit convoluted, but it all comes out okay in the end, right?

Steve Stout KA5CRI sends along a few circuits that will interest quite a few of you. Fig. 1 shows a low-voltage loop supply that Steve uses to run his Model 15. His terminal unit requires an external loop, as do many of the newer solid-state units, and using this low-voltage, current-limited supply has a side benefit of preserving the terminal unit's output transistor's life.

Fig. 2 is a circuit Steve put together to "expand" the loop to add another pair of selector magnets, which happened to be encased in a reperforator. In the old days, a power supply of 200 volts or so was used to run two or more RTTY machines in series. Stringing them together formed a "loop," thus the name, local loop (and, by extension, RTTY Loop!). But these days, with low-voltage transistorized outputs, putting two or more sets of selector magnets in series loads down the output to the point where the system will not operate; thus, this circuit. The optoisolator basically keys the second loop, and several of these circuits may be chained together to expand the loops *ad nauseum*. Thanks to Steve for passing these ideas along.

For the past several months, this columnist has been looking into a RTTY terminal program for a 6800-type computer. I have been told that such a program would interest maybe six people worldwide. Is that true? I may change my mind and pursue the 6800, but I am beginning to think that that may be a dead system for wide circulation. Mine is far from moribund, but is it a dinosaur at age seven? My current plans are to complete the "block diagram" discussion, which is processor independent, then look into program development for a 6502-based system, very possibly the Atari. As I said last month, the membrane keyboard is "feh," but I hope to acquire an upgraded Atari with a real keyboard and disk which would lend itself to developing such a program on it. The sound generation system in the Atari may also lead to AFSK without much bother; I don't know. Let me know what you think. Is the 6800 dead as far as you all are concerned? Would you rather see an Atari version? What features are important, which others are nice, fluff, or useless? Drop me a card to voice an opinion. It will count.

Next month some more on the above, and more from out there, all from in here, the old-fashioned, high-voltage RTTY Loop.

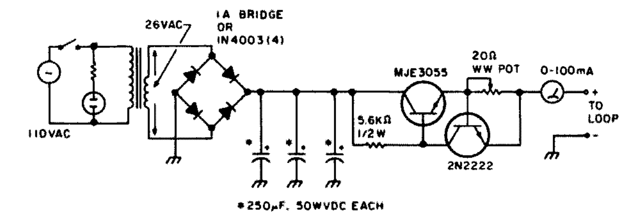

Fig. 1. Low-voltage loop supply.

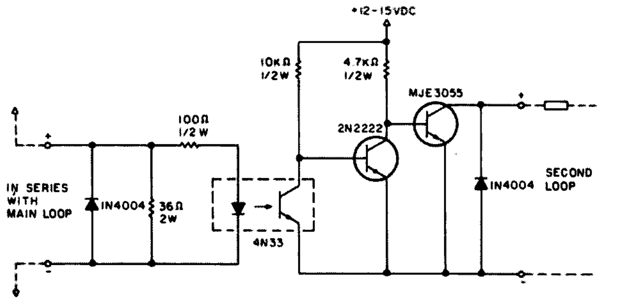

Fig. 2. Loop expander.

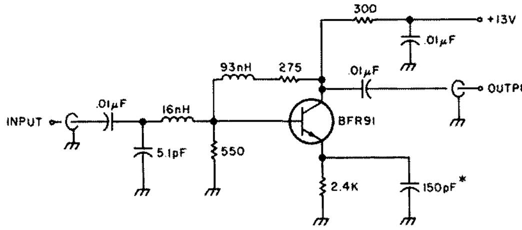
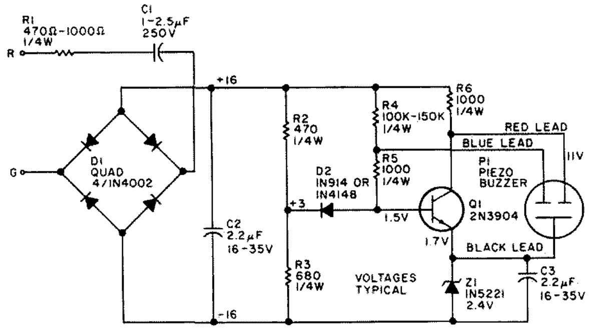
CIRCUITS

Do you have a technique, modification, or easy-to-duplicate circuit that your fellow readers might be interested in? If so, send us a concise description of it (under two pages, double-spaced) and include a clear diagram or schematic if needed.

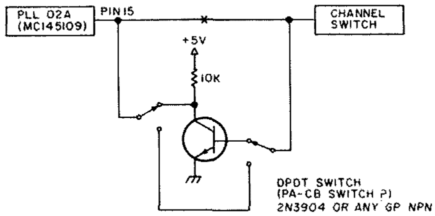
In exchange for these technical gems, 73 offers you the choice of a book from the Radio Bookshop, *to be sent upon publication. Submit your idea (and book choice) to: Circuits, Editorial Offices, 73* Magazine, *Peterborough NH 03458. Submissions not selected for publication will be returned if an SASE is enclosed.*



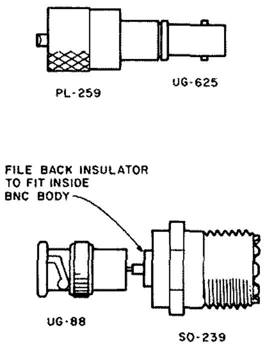
COMPUTER-OPTIMIZED LOW-NOISE BROADBAND AMPLIFIER: Used as a preamp for your tired receiver or to boost levels anywhere in a home-brew project, this amplifier provides 10 dB of gain from 10-600 MHz, and has a 1.5-to-1 match at 50 Ohms. The BFR91 has a 1.5-dB noise figure at 500 MHz, and the circuit requires 13.5 V dc at about 13 mA. The only construction caution is to keep the leads on the 150-pF emitter bypass capacitor as short as possible. I used a chip capacitor with excellent results. The 16-nH coil is 2.5 turns of #26 enamel wire on the shank of a #40 drill. The 93-nH inductor is 10 turns of the same material.—Rick Ferranti WA6NCX/1, Cambridge MA.



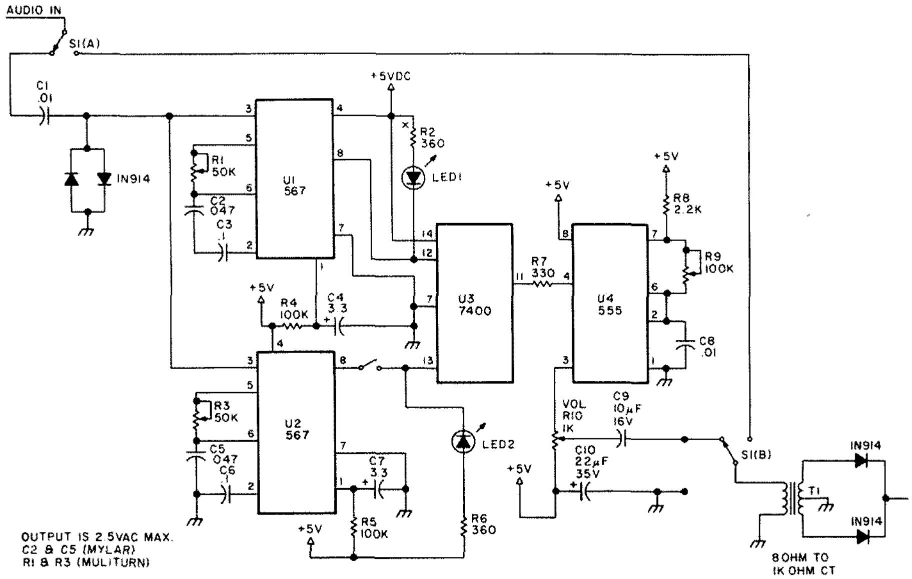
DING-A-LING: This electronic bell needs no power supply. The layout and most of the resistors are not critical, although C2, R2, and R3 work best at the values given. Leaving out R1 will make the unit ring louder. The piezo buzzer may vary from store to store, so if it has two leads, connect the red lead to the collector and the black lead to the emitter of Q1. If a third (blue) lead is present, connect it to the base of Q1.—E. C. Sherrill W5TPP, Fort Worth TX.



USE THOSE MISSING CB CHANNELS: Add more frequencies to your PLL CB-to-10 conversion by adding a switch and a transistor to invert the least significant bit going to the PLL chip. With the switch as shown, you can get 10 kHz above channels 3, 11, and 19, as well as 10 kHz below channels 8 and 16.—Bob Raker WB8ZFF, Cincinnati OH.



BETWEEN-CONNECTOR SERIES ADAPTER: A BNC female (UG-625) fits nicely in a UHF male (PL-259). Just solder a wire to the BNC center and insert it in the body of the PL-259. Solder the center conductor and the seam between the bodies. With just a little more difficulty, an SO-239 can be attached to a BNC male (UG-88). An "F"-type female will thread directly into a BNC male. SMA to BNC (both ways) can be done just as easily.—Bob Raker WB8ZFF, Cincinnati OH.



QRM ELIMINATOR FOR COMPUTER CW: Here is a dandy circuit which will filter out a substantial amount of QRM, enabling a computer to copy CW with ease. The LED on the output could be used to help the hearing-impaired to copy CW. The heart of the circuit is a pair of decoders tuned to slightly different tones which overlap each other. The outputs are fed to a NAND gate, which will key whenever a tone is detected by either detector. The operating bandwidth is now 200 Hz. This circuit will enable you to read CW in bad QRM and with low signal level. The bypass switch is used to check the band without the filter in place. A volume control connected to the output through a headphone or speaker will enable you to monitor the output.—Bill Buckingham WA3LIL, Osceola PA.

HAM HELP

Can anyone provide me with a manual for the Heath model O-10 laboratory oscilloscope? The manual is no longer available from Heath. I will pay all costs or copy and return.

Robert Ross VE3LPJ

Brampton L6W 2R4
Ontario, Canada

Wanted: 220- and 440-MHz boards for a UV-3 transceiver. I will pay a reasonable price for them.

Johnny E. Carr WA4FCC
Route #2
Rockmart GA 30153

Does anyone have a noise-blanker circuit that will work in a National HRO 500?

Bill Blackwell K8LO
180 Woodmere
Detroit MI 48209

I am looking for a new QSL service for outgoing QSL cards. Can anyone help me find one?

Paul Desharnais WA1IPD
22 Cote St.
Somersworth NH 03878

I would like to get a program for Oscars 8 and 9, as well as the RS satellites, for the VIC-20 with 8K. I am also looking for a hook-up to use a Model 33 printer with the computer. I will pay for tapes.

Jim Fyles WB0CZI
820 El Paso Blvd.
Denver CO 80221

I am compiling a list of amateur frequency use, including DX nets, special interest nets, calling frequencies, and band/mode limits. I need details or nets with their designated frequency as well as band limits from 1.8 MHz to 54 MHz.

Ash Nallawalla ZL4LM/VK3CIT
RAAF Academy
Point Cook VIC 3029
Australia

I need the original manual for the Johnson Viking Valiant—no copies, please.

Russ Lawson K1MOU
124 South Grand St.
West Suffield CT 06093

I need schematics and service information for the Knight KG-635 and Precision EG-550B oscilloscopes and the Digicom 800 2-meter radio.

Robert Ball KL7AH
PO Box 74645
Fairbanks AK 99707

I would like to find the manual for a DuMont model 304-A oscilloscope. I am willing to buy the manual or copy and return it.

Gordon Fulp W6FBH
4740 Scotch Pine Lane
Placerville CA 95667

I have a small dc motor that has good ball bearings. I want to use it as a drill motor for PC boards. How do I make a chuck to hold a drill bit with a 3/16" shaft?

Patrick Chirington
1478 Grace Ave.
Lakewood OH 44107

I am looking for an early-production-run Kenwood R-1000, preferably pre-1980.

Victor Barz
Rm. 3305 Cross-Baits II
Ann Arbor MI 48109

I need a schematic for the Tennelec model TN 800 scanner. I will pay for any copies.

Chuck McGinty
RR 11 Box 451
London KY 40741

I have a Pace model CB 144 CB radio which I converted to 10 meters. It receives on 10, but transmits on 21.269 MHz. Can anyone tell me how to get it to transmit on 10 meters?

Joe Oden WD0HVM
4129 South Wichita
Wichita KS 67217

I am seeking the schematic and owner's manual for a National NC-303 receiver. I will pay all postage and copying costs.

Jim Pemberton
7324 Oxmoor Dr.
Rt. 20
Knoxville TN 37921

Does anyone know where I can buy or how to make solid-state replacements for the 6X4 and 12AV7/12AX7 tubes?

Kevin Neal
Route A Box 221A
Flippin AR 72634

Can anybody tell me how to take incoming signals for a Motorola teleprinter and convert them to a format usable by a TRS-80 Model I? Any help or suggestions would be appreciated.

David Youngs
519 N. Pine Way
Anaheim CA 92805

CORRECTIONS

An incorrect drawing accompanied "Ni-cad Charger With Current and Voltage Limiting," which appeared in the "Circuits" feature on page 99 of February's issue. The two bottom diodes in the bridge rectifier should be reversed in order for the circuit to operate properly.

BATTERY ELIMINATORS FOR HAND-HELDS

Handi-Tek has announced its line of battery eliminators for a variety of hand-held radios. These voltage regulators allow continuous operation of handie-talkies without nicad drain or radio modification.

The eliminators plug into an automobile cigarette lighter and provide a regulated voltage supply for Icom, Kenwood, Yaesu, Wilson, Tempo, and other brands.

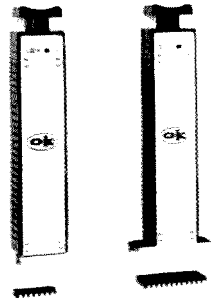
Constructed on glass-epoxy circuit boards from high-quality components, Handi-Tek regulators sport ample heat sinking and a sturdy plastic case.

The six models of eliminators supply a regulated voltage from 8.4 to 10.8 V and, in some cases, may be substituted for the radio's battery pack.

For more information, contact *Handi-Tek, PO Box 2205, La Puente CA 91746.* Reader Service number 485.

IC INSERTERS FOR PC BOARDS

OK Industries, Inc., has just introduced a new series of IC-insertion tools with dimensions optimized for direct insertion into PC boards without sockets. Special long body style facilitates firm grip and thumb action for accurate and comfortable one-hand operation. Rugged nickle-plated steel guides ensure durability and provide static safety, important when using MOS and CMOS ICs. Designed for 14-16-pin ICs (model BBI-1416) and 24-28-pin ICs (model BI-2428). These new inserters are available from stock at local electronics retailers and distributors nationwide, or directly from *OK Industries, Inc., 3455 Conner Street, Bronx NY 10475.* Reader Service number 479.



IC inserters for PC boards from OK Industries.

650-MHZ FREQUENCY COUNTERS

The new Models 6000 and 6500 650-MHz Frequency Counters, introduced by Global Specialties Corporation, offer outstanding performance and ease of operation. The 6000 features a trimlined front panel with optimally accessible controls, push-button operation, bright LED display, and extremely accurate frequency measurement from less than 5 Hz to more than 650 MHz. The standard Model 6000 Frequency Counter has a 3.579545-MHz temperature-compensated crystal oscillator time base. An optional crystal oven oscillator time base is available on the Model 6500.

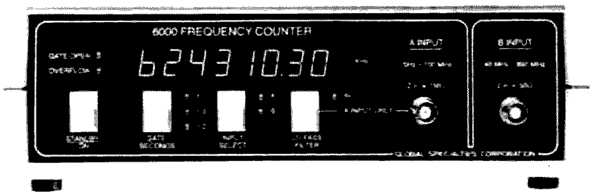
These frequency counters feature two front-panel-mounted BNC input connectors which allow greater flexibility in frequency measurement. The A input accepts signals from 5 Hz to 1 MHz with an input impedance of 1 megohm @ 25 pF. A switchable low-pass filter, with an LED indicator light, provides a 3 dB per octave rolloff at 60 kHz to facilitate audio and ultrasonic measurements. The B input is used for signals from less than 40 MHz to over 650 MHz with an input impedance of 50 Ohms @ 10 pF. Selection of A or B input is via a simple push-button control with LED indicators.

The 6000 and 6500 also feature three switch-selectable gate times, with simple push-button operation and LED indicators. This enables the user to choose gate times of 0.1 second with 10 MHz resolution, 1 second with 1 Hz resolution or 10 seconds with 1/10 Hz resolution. LED indicators for GATE OPEN and OVERFLOW provide additional user convenience.

The easy-to-read 8-digit LED display features leading-zero blanking, bright 0.43-inch characters, a decimal point in the kilohertz position, and a contrast-enhancement filter to ensure legibility in high ambient light.

The clean, well-designed front panels of the 6000 and 6500 allow ready access to controls and efficient operation. The easy-touch push-button controls include: Standby/on switch, Gate time selector, A/B input selector, and Low-pass filter in/out control. A flip-up leg provides added flexibility for benchtop use.

The 6000 and 6500 650-MHz Frequency Counters measure 3 × 10 × 7 inches (H × W × D), weigh 3.5 lbs., and come with a comprehensive instruction manual. For additional information, contact *Global Specialties Corp., 70 Fulton Terrace, PO Box 1942, New Haven CT 06509; (203)-624-3103.*



Global Specialties' Model 6000 Frequency Counter.

Kenwood's TS-430S HF transceiver.

TS-430S HF TRANSCEIVER

The TS-430S, a recent addition to Kenwood's line of high-frequency transceivers, is an all solid-state SSB, CW, and AM transceiver, with FM optional. Designed to cover the 160-10-meter amateur bands, including the new WARC bands, it also incorporates a 150-kHz-30-MHz general-coverage receiver having an exceptionally wide dynamic range. Other features include dual digital vfo's, eight memories, memory scan, programmable band scan, fluorescent tube digital display, all-mode squelch, VOX, speech processor, i-f shift, notch, and a NARROW-WIDE filter-selector switch for use with various optional filter combinations. For additional information, contact your local Kenwood amateur radio dealer, or write to: *Trio-Kenwood Communications, 1111 West Walnut St., Compton CA 90220.*

TC25G ELECTRIC GENERATOR

Thermax Corporation has just released the efficient new TC25G small-scale electric generator. The generator is designed to produce electricity at low rpm's.

The specially designed TC25G is ideal for battery charging in boats, in recreational vehicles, or at remote sites such as Field-Day or repeater locations. It will charge in any system from 6 to 36 V dc. A detailed manual is included with each generator. With each generator sold, Thermax offers free plans to build a wind, water, or pedal-power generating system.

For more information, contact *Thermax Corporation, One Mill St., Burlington VT 05401.* Reader Service number 478.

The TC25G generator from Thermax Corporation.

225-400-MHZ SCANNER CONVERTER

An improved 225-400-MHz scanner converter has been announced by Grove Enterprises. The new CVR-1B Scanverter includes a built-in preamplifier for increased sensitivity and allows complete coverage of the 225-400-MHz military/federal government aircraft band when used with a standard aircraft band scanner.

The unique Scanverter makes it possible for scanner listeners to hear NASA space shuttle support, military tactical communications, Coast Guard missions, federal government agencies in flight, and more.

An exclusive Grove Enterprises development called "bandstacking" allows the entire 175-MHz-wide UHF aircraft band to be compressed into the 118-136-MHz range, tunable on any scanner capable of standard aircraft reception. No tuning or adjustments are necessary with the fully automatic converter.

Reception for hundreds of miles is possible with the use of an outside antenna. Additional features of the Scanverter include:

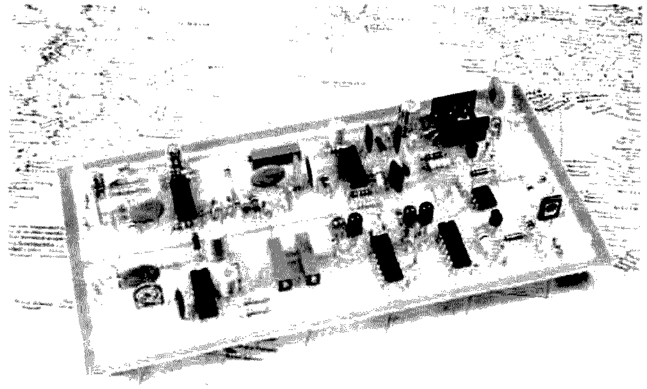
- high-sensitivity, low-noise microstripline circuit
- all metal cabinet for superior shielding
- double-balanced mixer for reducing images
- nine-pole filter for suppressing out-of-band interferences
- crystal oscillator for providing high stability
- zener diode voltage regulation to limit drift
- powered by convenient 12 V dc

A handy list of active nationwide UHF aircraft channels is included. The Scanverter comes complete with power cord, interconnect cable, and full instructions.

For additional information, contact *Grove Enterprises, 140 Dog Branch Road, Brasstown NC 28902; (800)-438-8155 (except NC). All others call (704)-837-2216.* Reader Service number 480.

RADIOTELETYPE AFSK MOD/DEMOD

Now available from GFS Electronic Imports of Mitcham, Victoria, Australia, is the MDK-17 RTTY mod/demod terminal unit. It is designed for HF and VHF amateur radio and/or commercial use at baud rates of 45 to 50 with a shift of 170 Hz. Other baud rates and shifts may be accommodated, but some component changes are necessary. The MDK-17's unique design makes for simple hookup to transceiver, Teletype*, and/or computer terminal. Its 10 ports provide for all combinations of TTL and high-



RTTY AFSK mod/demod terminal unit from GFS Electronic Imports.

voltage 20-60-mA send-receive systems. An open collector output allows direct keying of HF transceivers.

State-of-the-art circuitry is used throughout its design including the XR2211 IC which combines both limiter and active bandpass filter in the one package. The tone generator uses an XR2206 IC which allows for excellent temperature stability. Accurate setting of tone frequencies and demodulator center frequency is provided for by using 15-turn trimpots in these critical areas.

Other features include the provision to invert the signal sense in both the send and/or receive modes. LEDs are used to indicate transmitted tone and correct receiver tuning. An auto start output is available for driving TTL circuitry. Only a single +12-volt supply is required as the power source.

The kit is supplied with comprehensive easy-to-follow assembly instructions. Approximately two hours is required to assemble and test it.

For further information, contact *GFS Electronic Imports, 15 McKeon Road, Mitcham, Victoria 3132, Australia; (03)-873-3939. Reader Service number 481.*

HT POWER AMPLIFIERS

Mirage Communications' pocket-size B23 (2-meter) and C22 (220-MHz) power amplifiers, ever-popular with HT users and experimenters, have been upgraded for even greater versatility. A new power switch permits selection of full amplifier power on a non-energized bypass mode when only HT power is desired. The FM/SSB switch controls choice of rapid or delayed relay action. Power amplification is linear in either mode. The B23 produces 30 Watts (minimum) for 2 Watts in, 15 Watts for 1 Watt, etc. The C22 produces 20 Watts (minimum) for 2 Watts in, 10 Watts for 1 Watt, etc. Duty cycle of both amps is continuous. The B23 and C22 are made in the US and carry a 5-year general warranty with 1 year for power transistors.

For further information, contact *KLM Electronics, Inc., PO Box 816, Morgan Hill CA 95037; (408)-779-7363.*

HI-RIZER ANTENNA

Com-Rad Industries is introducing an even lower profile version of their popular Hi-Rizer restricted-space antenna. The height has been reduced from 20 to 15 inches to enable the portable/fixed antenna to be operated mobile! 40 through 10 meters are obtainable by the use of a 5-inch-diameter magnetic connection base or a vice-grip connection base with large metal surfaces such as automobiles, balcony rails, etc. A portable cylinder ground-plane system is available for use where metal surfaces don't exist. Construction consists of 3/8-inch-diameter aluminum tubing and stainless steel hardware throughout. For more information, contact *Com-Rad Industries, 1635 West River Parkway, Grand Island NY 14072; (716)-773-1445.* Reader Service number 484.

MULTI-MODE CODE RECEIVER

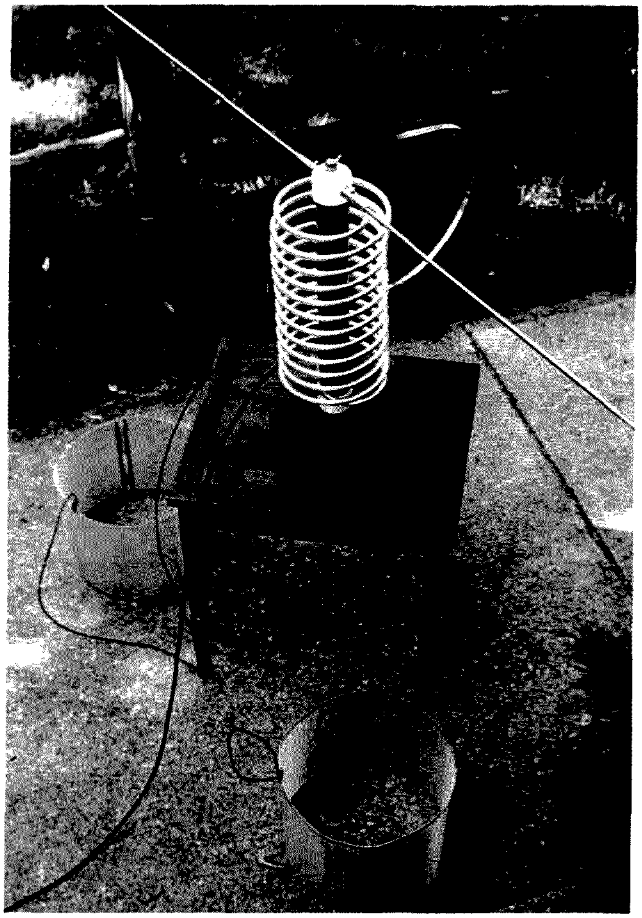
Universal Electronics has announced the new Universal M-600 multi-mode code receiver. The M-600 receives RTTY sent with bit inversion, TOR, SITOR, and nonstandard shifts. It also will be capable of copying AMTOR as soon as that mode is approved.

The M-600 also can receive all speeds of Baudot, ASCII, and Morse-code transmissions. Special features include an automatic speed search for ASCII and Baudot which will automatically find and lock onto the speed of the received signal.

The video output includes a 64-character ASCII set, a 5 × 7 dot-matrix display, and four formats. The cursor may be turned on or off, and the display also has automatic scrolling capability.

The printer interface includes a 2K buffer which allows downconverting and printer handshaking. An optional 60-mA/20-mA auto-adjusting loop supply is also available for the M-600.

For additional information, contact *Universal Electronics, Inc., 1280 Aida Dr., Reynoldsburg OH 43068; (614)-866-4605.*



Hi-Rizer restricted-space antenna from Com-Rad Industries.

CATV CONVERTER

Tayco's new Magnavox FV-25 CATV converter includes a 25-channel capacity and a remote control for easy use.

The FV-25 consists of the push-button remote control unit (housed in a high-impact plastic enclosure) and the con-

Upgraded B23 power amplifier.

The M-600 multi-mode code receiver from Universal Electronics.

verter, which is designed to be easily mounted near the television.

The converter provides up to 9 dB of gain, enabling distant location of the unit from the TV receiver. It has been designed to avoid interference from direct pickup of strong local signals. Input and output terminals are threaded, coaxial 75-Ohm F-type.

The remote control is connected by a 25-foot, two-wire shielded extension cable. The 13 push-button switches select the appropriate channel within either band, and the fine-tuning control permits minute picture adjustments.

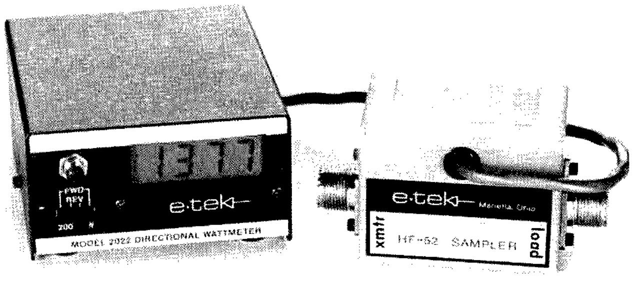
For additional information, contact *Tayco Communications, R3-146A Narrows Ck. Rd., Corning NY 14830; (607)-962-7313.* Reader Service number 482.

DIGITAL WATTMETER

E-tek, manufacturer of digital frequency readouts, has announced the introduction of a new digital directional wattmeter. The Model 2022 HF Directional Wattmeter features a high-contrast LCD readout of both forward and reflected power from 5 to 1999 Watts. Both the 199.9- and 1999-Watt scales provide an impressive improvement in resolution and readability when compared with conventional analog wattmeters. A new diode pre-biasing technique enhances accuracy over the entire 1.5-to-30-MHz frequency range.

Connected by an unpluggable cable to a remote rf sampler, the attractive readout unit measures only 3.6" W × 2.1" H × 4.0" D. The heavy 20-gauge steel cabinet is protected by a black, multiple coat, polyurethane finish accented by the brushed aluminum and black photo-anodized front panel. The high-contrast 0.5-inch black LCD digits are easily read from across the room.

Power for the Model 2022 HF Directional Wattmeter is provided by a standard 9-volt transistor radio battery rated for at least six months under normal use. Battery life is maximized by the use of a unique new low-power multiplier circuit and further enhanced by an rf-detecting automatic disconnect circuit.



Digital wattmeter and remote rf sampler from e-tek.

For further information, contact *e-tek, PO Box 625, Marietta OH 45750; (614)-374-2280.* Reader Service number 483.

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

CARF PHONE COMMONWEALTH CONTEST

Starts: 1200 GMT April 9
Ends: 1200 GMT April 10

This contest is open to amateurs in all countries of the Commonwealth of Nations. Entrants may work other amateurs in the Commonwealth using SSB only, on 80- through 10-meter bands. Work only stations outside your own call area. Each station may be worked once on each band. There is one entry class for single-operator stations in all- or single-band classes.

EXCHANGE:

RS report and a consecutive serial number, starting with 001.

FREQUENCIES:

3600, 3760, 7080, 14130, 21200, 28480 plus or minus 20 kHz.

SCORING:

Each completed contact will score 5 points. In addition, a bonus of 20 points may be claimed for the first, second, and third contacts with each Commonwealth call area on each band.

AWARDS:

A plaque will be awarded to the top scoring allband entry. Certificates will be awarded to top scorers in each class in each Commonwealth call area.

ENTRIES:

A valid entry must include log sheets, dupe sheets, a checklist of Commonwealth call areas worked on each band, and a summary sheet showing claimed QSO and bonus points as well as final claimed score calculations. Summary and call-area checklist sheets are available for an SASE. Entries should be mailed within one month of the contest to: CARF, PO Box 2172, Station D, Ottawa, Ontario, K1P 5W4 Canada. Results will appear in *TCA*, the Canadian amateur radio journal. Nonmembers of CARF may wish to include an SASE with their entries for a copy of the results.

CALENDAR

Nov 19-20	ARRL Sweepstakes—Phone
Dec 3-4	ARRL 160-Meter Contest
Dec 10-11	ARRL 10-Meter Contest

HOLIDAY IN DIXIE QSO PARTY

1800 to 2300 GMT April 16

Holiday in Dixie is an annual 10-day celebration held in Shreveport, Louisiana, commemorating the Louisiana Purchase. The event was first organized in 1947 and the QSO party event began in 1978. The radio amateurs set up stations at Hamel's Amusement Park on the Red River in Shreveport and operate 40 through 10 meters. For CW, look around the lower 60 kHz of each band. For SSB, check 7240, 14280, 21380, 28580.

Holiday in Dixie provides commemorative certificates to hams establishing 2-way contact with one of the HID stations. All that is required is sending a QSL card verifying the contact to Holiday in Dixie QSO Party, PO Box 1485, Shreveport LA 71164. Be sure to include signal report and the name and call of the HID operator you contacted. Don't forget an SASE!

In addition to the certificate, a commemorative doubloon will be sent to the first 100 stations. These doubloons are thrown out at the Classic Parade by HID vice presidents in downtown Shreveport.

ARBOR DAY CELEBRATION

Starts: 2400 GMT April 22
Ends: 0600 GMT April 25

A special events station will be operating from the Nebraska State Arbor Lodge, former home of J. Sterling Morton, founder of Arbor Day, in Nebraska City, Nebraska, during the annual Arbor Day Celebration. This station, in addition to other club member stations, will be operating in the general portion of the phone and CW bands on 80 through 10 meters. All amateurs contacting this station or any other club member station during this time will be eligible to receive an Arbor Day commemorative certificate from the Nebraska City Amateur Radio Club. Please send one dollar and a business size SAE to: Nebraska City Amateur Radio Club, Box 8, Nebraska City NE 68410.

QRP ARCI SPRING QSO PARTY

Starts: 1200 GMT April 23
Ends: 2400 GMT April 24

Stations may be worked once per band and mode for QSO multiplier credits. Participants may operate a maximum of 24 hours during the contest period.

EXCHANGE:

Members—RS(T), state-province-country, and QRP ARCI membership number.

Nonmembers—RS(T), state-province-country, and power output.

SCORING:

Each member QSO counts 5 points regardless of location. Nonmember QSOs are 2 points with US and Canadian stations; others, 4 points each. Multipliers are as follows: 4-5 Watts CW or 8-10 Watts PEP. . . ×2, 3-4 Watts CW or 6-8 Watts

The Minuteman

NEWSLETTER OF THE MONTH

From an area rich in Revolutionary War history comes this month's newsletter contest winner—*The Minuteman*, bulletin of the Minuteman Repeater Association, based in Lexington, Massachusetts.

This is a jam-packed newsletter for a vigorous and versatile club. The MMRA operates several repeaters in eastern Massachusetts, runs an active public service system, and involves itself in the technical education of its members. And there is a space for all of these activities in *The Minuteman*.

It is not unusual for *The Minuteman* to run 10 to 12 pages long, and little space is wasted. The reporting in the newsletter is succinct and informative. One recent issue contained an article on the care and feeding of nicads as well as an in-depth look at the status of MMRA's newest repeater. This article included not only what was done to the repeater and why, but it also contained oscilloscope-generated graphics illustrating key points of the machine's operation.

The issue also included an up-to-date listing of the middle-eastern New England repeaters and news of upcoming and past public service activities.

But all is not stuffed-shirt. One-liners are judiciously sprinkled throughout the newsletter, and the comments of the columnists are evidence that this club does not let business interfere with levity.

Congratulations to *Minuteman* Editor Bill Shaughnessy WB1GVA for his fine work.

To enter your club's newsletter in *73's* contest, just send it to *73*, Pine Street, Peterborough NH 03458.

PEP . . . × 4, 2-3 Watts CW or 4-6 Watts PEP . . . × 6, 1-2 Watts CW or 2-4 Watts PEP . . . × 8, less than 1 Watt CW or 2 Watts PEP . . . × 10. Entries from stations running more than 5 Watts output CW or 10 Watts output PEP will count as check logs only. Stations are eligible for the following bonus multipliers: if 100% natural power (solar, wind, etc.) with no storage, × 2; if 100% battery power, × 1.5. Final score is total QSO points times total number of states-provinces-countries per band times the power multiplier times the bonus multiplier (if any).

FREQUENCIES:

CW—1810, 3560, 7040, 14060, 21060, 28060, 50360.

SSB—1810, 3985, 7285, 14285, 21385, 28885, 50385.

Novice/Tech—3710, 7110, 21110, 28110.

All frequencies plus/minus to clear QRM. No 30-meter contacts will be counted!

AWARDS:

Certificates to the highest scoring station in each state, province, or country with 2 or more entries. Entries automatically considered for annual Triple Crown of QRP Award.

LOGS AND ENTRIES:

Separate log sheets are suggested for each band for ease of scoring. Send full log data, including full name, address, and bands used plus work sheet showing details and time(s) off air. No log copies will be returned. All entries desiring results and scores please enclose a business size envelope with return postage for one ounce or an IRC. It is a condition of entry that the decision of the QRP ARCI Contest Chairman is final in case of dispute. Logs must be received by May 21st to qualify. Send all logs and data to: QRP ARCI contest chairman William W. Dickerson WA2JOC, 230 Mill Street, Danville PA 17821.

TSRAC SCAVENGER HUNT CONTEST

Starts: 0000 GMT April 23
Ends: 2359 GMT April 24

Sponsored by the Triple States Radio Amateur Club, this contest is based on the old-fashioned scavenger hunt in which each person was given a list of items to find and the person who found all or most of the items was declared the winner. CW and phone contacts are both allowed.

EXCHANGE:

Normal QSOs or "CQ TSHT TEST."

FREQUENCIES:

20 kHz above the bottom of any General or Novice band.

SCORING:

The scoring is the unique part of the contest. You make points by finding and making contacts in specified geographic areas. Contact with 7 of the 10 call areas is worth 10 points, with 1 point for a duplicate area contact and a 15-point bonus for making contact with all 10 call areas. One QSO with a Canadian station is worth 5 points, with 1 more point given for each additional Canadian contact. A contact with a 1 × 2 or 2 × 1 callsign is worth 5 points, and 1 point is given for each additional QSO. The first contact with a 2 × 2, 1 × 3, or 2 × 3 US callsign is worth 5 points, with an extra point for each additional contact. A QSO with any DX station except Canada nets 10 points and a 2-point bonus for subsequent contacts. The first QSO with a TSRAC member is worth 5 points, and there is a 2-point bonus for each subsequent contact. One contact on each band from 80-10 meters (except 20 and 30) gets 10 points, and the first QSO with a YL is worth 15 points, with 3 points given for each subsequent contact. 100 bonus points are given if the contestant scores on all 10 items.

ENTRIES:

Send your entry no later than May 25 to contest chairman David M. Kinney KC8YR, RD #1, Mingo Junction OH 43938.

AWARDS

Bill Gosney KE7C
Micro-80, Inc.
2665 North Busby Road
Oak Harbor WA 98277

THE WAVO AWARD

WAVO (Worked All VO) is available to any amateur not a resident of Newfoundland or Labrador, operating from one call area, who can show proof of two-way contact with forty different stations operating fixed, portable, or mobile in the province. One of these stations must be using a VO2 Labrador prefix.

WAVO is also available to all VO, VO mobile, or VO portable stations operating either VO1 or VO2 (not both in one application) that can show proof of two-way contact with sixty different stations operating fixed, portable, or mobile within the province. Two of the stations worked must be using a VO2 Labrador prefix.

WAVO VHF is available to amateurs who show proof of contact with twenty stations using a simplex mode of operation. Repeater operation is not permitted. All contacts must be later than June 1, 1946. No endorsements are available.

QSL cards are not needed as proof of contact. The log-book entries must be certified by an executive of a recognized club or two other amateur operators. The submitted list of log-book entries must include the call of the station worked, date, time, band, mode, signal report given to the VO station, and the signed report received from the VO station.

WAVO applications should be sent to: VO1FG Awards Chairman, PO Box 501, Carbonear, Newfoundland, Canada.

WORKED ATLANTIC PROVINCES AWARD

To qualify for this award, eleven VE1 amateurs must work eight different counties of Nova Scotia, eight different counties of New Brunswick, two different counties of Prince Edward Island, and five different counties of Newfoundland. All other stations must work four different counties of Nova Scotia, four different counties of New Brunswick, one station in Prince Edward Island and three different Newfoundland stations.

QSLs must be in the applicant's possession. To apply, send log data and 50 cents or 5 IRCs to: Walt Jones VE1AMR, 79 Waverley, Moncton, New Brunswick, Canada E1G 7T8.

WORKED ONTARIO COUNTIES AWARD

The Worked Ontario Counties contest is intended as an operating challenge to radio amateurs and to encourage the working of Ontario stations by those located beyond as well as within the province.

Two Worked Ontario Counties certificates are offered. The first, WOC-30, will be awarded to each operator submitting QSL cards representing thirty of the counties in Ontario. The second, WOC-50, will be awarded to an operator submitting an additional twenty cards representing an additional twenty counties. It is not necessary to obtain the WOC-30 before applying for the WOC-50.

The Province of Ontario consists of 54 counties and districts. The word county, as used in connection with the WOC contest,

will be understood to mean county and/or district.

For the purpose of these awards, Lennox and Addington (though politically merged into a single county) will be scored as two counties. The four townships in the southwest corner will be considered Lennox and the balance of the county Addington. The Lennox townships are Richmond, North Fredericksburgh, South Fredericksburgh, and Adolphustown. Napanee is in Lennox; Odessa, Camden East, and Cloyne are in Addington.

Also, Patricia will be considered to be all that part of Kenora situated along or north of the CNR main line from Cochrane to Winnipeg and will score as a separate county. Red Lake, Pickle Lake, and Sioux Lookout are eligible in Patricia.

Contacts must be made, using your own equipment, from the home location or from within twenty miles from the home location. Contacts made from outside the home county will not count for the operator of the mobile but may be scored by the other operator in the QSO as a contact for the county in which the mobile is located. Each QSL card must show the county in which the issuing station was located at the time of the QSO. Each station must work the other directly with no relaying of information by way of intermediate stations.

Contacts may be made on any band, and any mode or combination of modes may be used. Any contact made on or after January 1, 1957, may be included. There is no deadline unless otherwise announced at some time in the future.

All regulations enforced by the Department of Communications applying to amateur radio stations shall be observed by Canadian stations. Similarly, stations in other countries must observe the regulations of their respective governments.

Cards for judging should be mailed to the awards manager. Although the club will endeavor to return all cards safely, no responsibility can be assumed for cards which may be lost in transit. Sufficient postage must be included for the return of your cards by the method you specify.

In case of dispute on any matter relating to the WOC contest, the Executive Committee of the Metro Amateur Radio Club will decide the issue and their decision shall be final. Mail applications to: Awards Manager, Al Brown VE3AB, 360 Manor Road East, Toronto, Ontario, Canada M4S 1S2.

FRASER VALLEY DX CLUB AWARD

To apply for this distinctive award, Canadian and American stations must contact fifteen club members. DX stations contact five. All contacts must be after May 1, 1978.

To apply, typical log information is required. Canada and USA stations forward $1.00 with your log data and DX stations may send five IRCs. Mail them to: Fraser Valley DX Club Awards Manager, Howard Martin VE7AFY, 45-9960 Wilson Road, Ruskin, British Columbia, Canada V0M 1R0.

THE WINNIPEG DX CLUB AWARD

The award consists of a personalized presentation case containing a genuine new Canadian silver dollar issued by the Royal Canadian Mint.

Amateurs throughout the world are eligible but American and Canadian applicants must be members of the DXCC and must submit the number and date of the DXCC certificate. Amateurs in other countries of the world do not have to be DXCC holders in order to qualify for the award.

All contacts must be made after January 1, 1970. Thirty-one are necessary, representing five from each one of the continents of Africa, Asia, Europe, North America, South America, and Oceania; also necessary is one contact from any Antarctic station. The five contacts from each continent may be from different countries on that continent, but the five North American contacts must be with members of the Winnipeg DX Club. Members of the club include: VE4s: AA, AE, AH, AS, AT, BJ, CJ, EW, MP, RP, SA, SK, SL, SW, XJ, and SN.

QSLs for all contacts must be in the applicant's possession. To apply for this award, send certified log data and fifteen IRCs or $3.00 to: Sandy Wohl WE4SW, 33 Cherryhill Road, Winnipeg, Manitoba, Canada R2V 2L1.

SKI CANADA AWARD

Eric Walden VE3HLL advises us that he is award manager for the Ski Canada Award. To qualify for this certificate, all amateurs must work two stations from each of the major skiing provinces: British Columbia, Alberta, Ontario, and Quebec. A total of eight contacts is required. All contacts, to be valid, must be made on or after January 1, 1978. There are no band or mode limitations.

The major ski areas from each province are: for British Columbia: Vancouver, Vernon, Kamloops, Penticton, Kelown, Kimberley, Princeton, Revelstoke, Nelson, Prince George, and Port Alberni; for Quebec: Montreal, Quebec City, Saint Jerome, Saint Adele, Saint Jovite, and Sutton; for Ontario: Collingwood, Thunder Bay, Ottawa, London, Barrie, Kitchner-Waterloo, Huntsville, Orillia, Brace Bridge, Own Sound, Flesherton, Sault Saint Marie, and Meaford; for Alberta: Calgary, Edmonton, and Banff.

Applicants are asked to send all log data and $2.00 to: Eric Walden VE3HLL, Rural Route 1, Gowanstown, Ontario, Canada N0G 1Y0.

FRAMINGHAM AMATEUR RADIO ASSOCIATION

The Framingham Amateur Radio Association, Framingham, Massachusetts, will commemorate its 50th anniversary by awarding certificates throughout 1983 to any station contacting the club station, W1FY, or three club members.

Send a large SASE and log information to FARA, PO Box 3005, Framingham MA 01701.

W1FY will operate on Saturday mornings from 1400Z to 1600Z on phone, 14.280-14.290.

ALAMO VILLAGE DXPEDITION

Members of the Border Amateur Radio Society and the Uvalde Radio Club are offering an award to stations who work the clubs' annual Alamo Village DXpedition.

A handsome certificate depicting the main street of this replica of the famous Texas shrine will be sent to all stations that work the DXpedition and send an 8 × 10 SASE.

The Alamo Village station will be operating from 1800 UT April 16 to 1800 UT April 17 on the phone and CW portions of 40-10 meters.

SASEs should be sent to the Border Amateur Radio Society, PO Box CQ, Brackettville TX 78832.

READING RAILROAD 150th ANNIVERSARY

To celebrate the Reading Railroad 150th Anniversary, WB3AAL will operate on April 1, 2, and 3 from 1300Z until 2330Z, daily. Frequencies: 7.250, 14.300, and 21.375, plus or minus 5 kHz, starting on 7.250 at 1300Z and working on up in frequency every one and a half hours; Novice—21.150 daily from 1600Z until 1730Z. The first 150 contacts will receive a certificate; after that, contacts will receive a special QSL card celebrating this anniversary. To receive the certificate or QSL card, please send your QSL card with one US dollar to: Ronald J. Polityka WB3AAL, 1046 Weiser St., Reading PA 19601.

Santa Rosa CA 95402

SUITLAND ISLAND —A NEW ONE?

In late September last year, a station signing KJ6DO/KH7S appeared on the bands, claiming to represent a new country. Almost 2000 amateurs fought their way through the pileups to work the station, in the hopes of catching this "new country." Within a few hours, however, the word was out: KJ6DO/KH7S was a pirate, a bootleg station, and contacts with the station had no DXCC value.

The Suitland saga had started earlier that month when the various DX bulletins received a letter purportedly from an amateur radio club on Johnston Island in the North Pacific. The letter included a copy of a map labeled Suitland Island, a thousand miles north of Hawaii. Also enclosed was a news release draft suggesting Suitland was a top-secret military base being returned to civilian control and a copy of a letter to Don Search W3AZD at ARRL headquarters, requesting separate-country status for the previously unknown island.

Fig. 1. DXers taken in by the Suitland hoax last fall will get this reminder of their eagerness from their QSL bureau.

Since one of the requirements for new-country status is a successful operation from the island, the radio club stated that they would be on the air from Suitland in a matter of weeks with the call KJ6DO/KH7S. All the DX bulletins dutifully shared the information with their readers.

On the announced day a station with that call did indeed come on the air and began working the pileups. As the operation continued, a few amateurs began to notice some strange facts. The KJ6DO/KH7S signal was weak and fluttery in California, as though the station were located on the West Coast and not the Pacific. W5 stations beat out the W6 stations to "Suitland"—not likely if the station were really in the North Pacific. Then Lee Wical KH6BZF took a careful beam heading on the station, using the sharp null on the side of the antenna pattern. The heading was 60°, or directly toward the States, and not north or northwest as the advertised location of Suitland would suggest.

These irregularities prompted listeners to ask questions about location, permission, etc. The KJ6DO/KH7S operator gave evasive replies. After a while, KH6BZF relayed the information that the Suitland operator was giving his QSL manager as HØAX. Eventually the station shut down, the fun over.

The Suitland hoax was not a typical pirate operation. Not many amateurs provide advance information on their hoaxes. Should the DX bulletins have been more skeptical about the letter? The letter to the DX bulletins with maps and background information looked, on the surface, to be legitimate. But a close examination of the information reveals numerous clues for the skeptical DXer. The mere fact that there is no public record of the island should have been warning enough; in these days of satellite photography and the Freedom of Information Act, anyone can obtain detailed maps of the area, including the ocean floor. Not only do such maps show no island in the area, but there also are no seamounts or undersea mountains. Did the US military forge every undersea map to hide their secret island? Unlikely!

The map contains other clues suggesting a hoax. The magnetic deviation on the compass rose puts the map on the east coast of the US. The park, cemetery, railroads, and churches are not typical of a top-secret military base. The airport runway is a mere 3000' long, totally inadequate for the stated purpose.

The letter announcing the "DXpedition" also might have aroused the suspicions of a careful observer. The group specifically requested *no* contributions and *no* SASEs

Photo A. Martti Laine OH2BH (right) led a group of 60 hams to Aland Islands for the CQ WW contests.

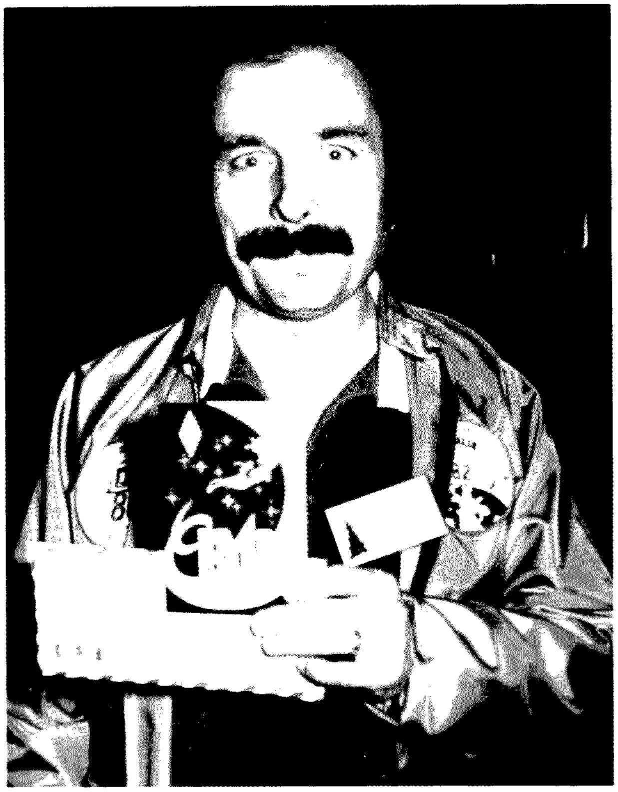

Photo B. "I can't believe I worked the real thing!" Redwood Empire DXer, Len Geraldi K6ANP, flashes his BY1 QSL, his first real QSL after five contacts with pirate BY1AAs.

with the QSLs. The QSL address was an APO box with no stateside manager. It would be hard to imagine a legitimate DXpedition setting up such a strange QSL route.

But this analysis has been made with the benefit of hindsight. It does not surprise me that the bulletin editors were taken in by the documentation; so seldom do they get such good information far enough in advance to be useful that they eagerly published the data.

The Suitland hoax did not end with the last contact, as most such operations do. A couple of months after the operation, QSL cards (see Fig. 1) began to appear in bureau shipments. If you were among those hams who worked Suitland, keep an eye out for your card.

Suitland was not the only amateur radio hoax of 1982. Dozens of amateurs worked a station signing BY1AA (see this column, July, 1982) last year. Unfortunately, this station was *not* located in China. Bootleg BY1AA stations made far more contacts than did the real China reporter.

Any amateur working a station signing BY1AA would immediately shoot off a QSL card with an SASE and hope for the best. Most of these amateurs received a nice postcard in return, but no QSL card. The card says, "Sorry, your QSO not in log. You must have contacted a bootleg station. Better luck next time." And most of these hams honestly thought they worked BY1AA. A station signing that callsign acknowledged their call. Unfortunately for the stateside amateur, the station signing BY1AA was not the legitimate one, and the contact does not count for DXCC.

While bootleg BY1AA stations worked dozens of stations, some other unusual callsigns attracted considerable attention. Every April 1st, dozens of strange calls appear on the bands, and many attract sizable pileups. Long-time DXers have learned to ignore the CQ DX of such stations as APR1L, F0OL, and that famous Russian RG8U!

Such antics are by no means limited to April Fool's Day. Hardly a day passes without some bogus station making a handful of contacts, then quickly disappearing. Many of these stations sound legitimate and reasonable, often using names and QSL addresses of active DXpeditioners.

Your DX editor's callsign has been taken in vain by several phony operations. I was supposed to be in Macao, operating CR9, one week. Another bootleg operation using my call as QSL manager was a European station signing an HI9 call who worked dozens of fellow Europeans on 80 meters. Many of those European stations thought they had snagged a rare one on 80 meters, only to receive word that the operation was bootleg and the contacts valueless.

Why would otherwise skeptical amateurs line up to work RG8U? The answer is "Work 'em first; worry later!" Too many DXCC countries have appeared on the bands suddenly, without warning. Perhaps a well-traveled DXer in the country managed to talk a government official into permitting a short operation session. In any case, the stateside DXer might get only one chance at a contact before the rare station disappears again. Rather than waste valuable operating time discussing the legitimacy of the station, the stateside DXer jumps into the pileup with both feet to make a contact, just in case.

This attitude prevails especially among the DXers with 250 or more countries. These amateurs have worked almost every country with active amateurs. Now they must await a DXpedition, or reactivation of a long-quiet country. Small wonder that these operators jump at any new or different callsign, especially when the magic phrase "new one" is bandied about. Whenever a new country or even an unknown callsign appears on the band, those DXers striving for the Honor Roll feel they must "get in the log," on the chance that it might count for DXCC. This group of avid and undiscriminating DXers provides an inexhaustible pool of contacts for hoaxers and bootleggers.

The motivation on the other end, although I cannot condone it, is easier to understand. What amateur, after years of fighting DX pileups from the States, Europe, or Japan, wouldn't enjoy being on the receiving end of a pileup for a change? But this means going to a rare country, getting permission to operate, setting up a station, and then answering all those QSL cards. Too much work. It's so much easier just to use the rare callsign!

How can you recognize a bootleg operation? No infallible rules can separate legitimate contacts from bogus ones—one reason why there are so many bootleg operations. You have to look for a pattern of behavior to recognize the culprits. First, almost all bogus operations are conducted on CW. It is so much more difficult to ask penetrating questions on CW as opposed to phone, and those questions are easier to ignore on CW as well. Bootleg stations tend to omit such data as name, QTH, or operating schedule. A notorious bootlegger used the name "Slim," and that name has since come to mean any illegitimate operation, as in, "I think that BY is a Slim." Another possible clue is the QSL information. If a very rare station suggests QSLing via the bureau, you should beware. The QSL bureau is seldom the preferred means of exchanging cards, especially among the more impatient DXers. A station requesting cards *only* via the bureau might be pulling your leg.

Some hoaxes have been less than pleasant. Don Miller once claimed he operated from Maria Teresa reef in the Pacific. Satellite photographs eliminated any chance that an unknown island might still exist. This and other frauds eventually forced the ARRL to disallow DXCC credit for many of Don's claimed DXpeditions. A lawsuit against the League followed, but Don's word was discredited and one of the longest and most widespread DX hoaxes came to an end.

Fun it may be, but hoaxing is also illegal. FCC regulations specifically prohibit transmission of "false or deceptive signals." Also, using another callsign without proper permission is prohibited. The perpetrators of the hoax probably avoided mail fraud by specifically *discouraging* contributions and SASEs, but the federal government has a lousy sense of humor in these matters.

The reaction of the DX bulletins to being taken in by the Suitland hoax reflects the different attitudes of DXers toward such shenanigans. *The Long Island DX Bulletin* cried foul, mentioned a "full-scale federal investigation," and ended, "We're sure you agree that this sort of thing just *ain't funny*!"

On the other hand, *QRZ DX* called the hoax "a good afternoon of late summer's fun and excitement." The Texas-based newsletter even congratulated the perpetrators of the hoax, "who reminded us once again that this really is just a hobby and just for fun."

This writer tends toward the *QRZ DX* viewpoint. After all, DXing is only a game, and one shouldn't take the whole thing too seriously. But this does not suggest that amateur radio needs more such hoaxes. As long as the joke is done in the spirit of good fun and money stays out of it, a good hoax once in a while livens up the bands. But it would be very easy to have too much of this good thing. In short, a little fun goes a long way on the DX bands.

So the first time you discover you worked a pirate, don't be disappointed or discouraged. After all, you are in good company. Every DXer has worked Slim many dozens of times. If you find yourself on the list for RG8U, discover your BY1AA contact was a pirate, or find a black QSL with a skull and crossbones in your bureau shipment, remember that you're not alone.

HEARD ON THE LONG HAUL

Tahiti—FO8 Ross Forbes WB6GFJ passes on word of the new address for the Tahiti QSL bureau. Send your FO8 cards to: Radio Club of French Polynesia, B. P 5006, Pirae, Island of Tahiti, French Polynesia, South Pacific Ocean. Don't send cards for FO0 calls, as these are usually visitors to the islands and will not receive cards sent to Tahiti. Find a stateside manager or QSL address.

Philippines—DU Rick Todd N8CWX offers CW contacts from the Philippines. Drop him a line via PSC#2 Box 12956, APO San Francisco CA 96311. QSL via N2BCF.

Abu Ali—/A Lloyd and Iris Colvin (W6KG and W6QL) stopped at this small rock in the Red Sea long enough to make 4000 contacts, with the help of F0ECV and F6GBQ. QSL via Yasme, Box 2025, Castro Valley CA 94546.

Aland Islands—OH0 Martti Laine OH2BH (see Photo A) and 60 other Finns put OH0W on the air for the CQ WW contests last fall. The group gave out 30,000 contacts from the islands, which lie between Sweden and Finland in the Baltic Sea. QSL your OH0W contacts via OH2BAZ, Patolantie 10A10, 00640 Helsinki 64, Finland.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 8

nese and you'll see the difference. Our ZL friend finds he has to glue decals back on, straighten screws, and in some cases respray the cabinets. Sloppy workmanship and little, if any, quality control.

The Japanese are almost fanatics when it comes to both workmanship and quality control. Indeed, I'd like at this time to ask *what few American manufacturers there* are left if they will take a pledge to see that their products are quality perfect. This means a final test of every unit and meticulous inspection. It also means after-sale support with information and replacement parts.

In order to help all of the firms in our ham industry, I'm asking readers, readers anywhere in the world, to let me know which firms you've found put out the best products and support them the best and which you've been disappointed in or have given you a hassle when you've had a problem. You can be sure that I'll pass the word along to the appropriate people in the firms involved. Those with strong recommendations will get a listing in my column.

EARPHONE JACKS

One of the conveniences starting to show up on car stereo radios is an earphone jack. Just in case you are not a stereo fan, let me explain that no loudspeaker system can be quite as good as a good earphone system for hearing sound. Oh, with some good speakers, high-power amplifiers, and so on, you can do a pretty good job. . .but it won't be better than phones.

I put in a pair of Ads speakers and an Ads amplifier in my 280Z and the sound was superb. Then I tried to duplicate the installation with the Jaguar and the sound came out terrible, despite an awesome investment. Someone swiped the 280Z speakers but forgot the matching amplifier (ha), so I wasn't able to duplicate exactly the winner I had in the 280Z. Woulds't that the radio in the Jaguar had stereo phone jacks.

Since one of the more serious problems with most amateur radio mobile installations is the crummy voice quality which results from low audio power, a cheap little speaker, and often the speaker not being aimed at the driver, what would it hurt to put in one or two phone jacks? Two, I recommend, so the passenger can be in on the conversation. It would be a lot easier to hear and the quality would be enormously better.

Yes, I know that there are some states where it is illegal to wear headphones in the car. The law doesn't make a lot of sense to me, but then there are a lot of laws which fit that category. Sure, I know that if you are listening to loud music with earphones you might not hear a car hooting at you, but if the radio is up to the usual rock and roll volume, you aren't going to hear anything either. . .and your hearing is probably well on the way to being ruined for life.

But instead of arguing the point, why not just come up with a solution which is better? *Here it is: How about an outside mike* to pick up loud traffic noises and override the music? Any of you who have Walkman stereo players know there is a little mike built in and an override switch in case you want to talk over the music. Well, with an outside mike and an electronic override switch, you'd get the car hoots better than you might if you had no earphones. The circuit is simple and would add little in expense to the radio. . .but a lot in value.

Just in case any car radio people are reading this, what is the matter with you turkeys? You finally, grudgingly, have given us FM in our car radios, but you're still behind. Many of the new Japanese cars are coming through with AM/FM/TV sound now. . .yep, an audio tuner for the television channels so you can at least hear the audio portion of shows. And many require not much more than that. Let's start seeing some three-band car radios with two earphone jacks.

One more thing. With the newest in earphones, no one is going to know you're using 'em in the car. These are tiny phones which are in a wad of soft foam plastic, but with no headband. You just stick the foam into your ear and it holds fine with the thin wires hanging down. These are the latest for the Walkman radios and also are used for the wrist-radios.

SEE YOU AT DAYTON?

The conditions under which I tried to talk last year were so frustrating that I didn't really want to do that again. It was hot and stuffy and the noise from adjacent sessions was so bad that it was almost impossible to talk. The Dayton people suggested a Friday talk, where there would be no nearby sessions, thus keeping the noise down. Well, I'll give it a try.

They always want to know ahead of time what my subject is going to be so that they can put it into the program. I unkindly point out to them that as far as I know, no one ever consults the program, during or after the Hamvention. But that doesn't stop the need for an answer.

I'll put it up to you. Presumably, a fair percentage of you will be coming to Dayton this year, so what would you like to hear about? Drop me a line and give me some ideas, if you will.

1. Packet radio. I can explain what this is, how it works, and why I see a big future for it in amateur radio. This is a computer-oriented communications system which can be made high-speed and error-free. It can work with a single channel repeater, thus taking up less spectrum space. This is an area where an enterprising experimenter could come up with a good commercial system which could then be manufactured and be quite profitable. Certainly, there is going to be a growing market for ham packet-radio equipment.

2. No code. . .if anyone really wants to hear about that any more. It's been about beaten to death. . .without any sign that the FCC is going to slow down in moving toward a no-code license. Is it possible that we might even see more interest and enthusiasm for the code if it were not dictated by the government? I can also give some hints on just how the FCC is going about getting rid of the code.

3. What is the future of emergency communications and what part will amateur radio play in it? Will our country be able to get prepared to provide dependable communications in time of nuclear war? What is the role of the new FCC Long-Range Planning Committee and what has happened to the many NIAC groups which we have had for years and which have recently been completely reorganized? Where does amateur radio fit into the picture?

4. How possible are the rumored plans for routine amateur communications via commercial satellites? How could this be organized and what commercial hay can be made from the needs for equipment?

5. What role do computers have now in amateur radio and where is this going? Are we headed toward ham communications which will be largely digital, with automatic error-free relaying of messages anywhere in the world? How practical is it to get in on computers and amateur radio right now?

6. Should amateur radio be considered a total failure and disbanded as an almost total waste of radio spectrum?

7. How can you use your ham skills to start a small business at home and build it up to where you are independent?

8. What are the prospects for getting amateur-radio clubs started in schools and thus getting amateur radio into a strong growth mode. . .with the possibility for providing our high-tech firms with enthusiastic technicians and engineers so that they can start competing with Japan? Or has America lost its high-tech lead forever?

9. Should anyone really care that ham licenses can now be gotten by people with absolutely no knowledge of code, theory, or rules via the Bash materials? We already have a code-free license, for that matter, so why the fuss about Morse code?

10. We try to make *73* reflect your interests. . .yet when we mail out letters to non-subscribers we often get only a few percent response. What, if anything, can be done to arouse the interest of the majority of licensed amateurs in *73*? Should we just capitulate and put out a rag-chewers magazine and forget editorials, computers, repeaters, slow-scan, RTTY, packet radio, and so on? Is the interest in small construction projects dead?

Well, there are some ideas. I can also hold forth at great length on the ways to get in there and make millions of dollars via some of the new small computers which are on the market. . .but I get the impression that hams in general prefer to remain poor, complain about subscription rates, go on social security, and not be really interested in getting rich. Pity, for through some of my magazines I've helped to make hundreds upon hundreds of new millionaires. . .and I probably could help do it for you, if you weren't so set on being poor. And with some of the opportunities in communications just ahead, the door is opening for enterprising hams to get some of the action.

Please do drop me a QSL card or a note and let me know what you'd prefer to hear at Dayton. Pick one subject, okay? This isn't going to be a speaking marathon like I pulled when I visited South Africa.

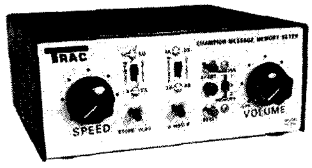
TRAC



Features:
- State-of-the-Art-CMOS Circuitry
- Choice of Message Storage
  - A. Six 50 character messages
  - B. Twelve 25 character messages
  - C. 27 combinations of message C programming
- Records at any speed—plays at any speed.
- Memory operating LED
- Use for daily QSO or contests

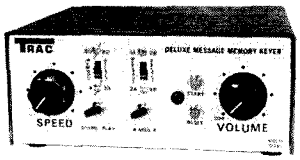
PLUS:
- Self completing dots and dashes
- Both dot and dash memory
- Iambic Keying with any squeeze paddle
- 5-50 w.p.m.
- Speed, volume, tone, tune and weight controls
- Sidetone and speaker
- Low current drain CMOS battery operation—portable
- Rear panel Jack for auxiliary power
- Deluxe quarter inch jacks for keying and output
- Keys grid block and solid rigs
- WIRED AND TESTED FULLY GUARANTEED—LESS BATTERY

CHAMPION MESSAGE MEMORY KEYER

Model TE-292

$125.95

DELUXE MESSAGE MEMORY KEYER

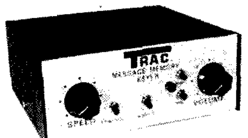


$89.95

Model TE-284

Features:
- State-of-the-Art CMOS Circuitry
- Three choices of Message Storage
  - A. Two (50 character each) message storage
  - B. Four (25 character each) message storage
  - C. One 50 character and two 25 character message storage
- Records at any speed-plays at any speed
- Memory operating LED
- Use for daily QSO or contests

PLUS:
- Self-completing dots and dashes
- Both dot and dash memory
- Iambic Keying with any squeeze paddle
- 5-50 w.p.m.
- Speed, volume, tone, tune and weight controls
- Sidetone and speaker
- Low current drain CMOS battery operation-portable
- Deluxe quarter-inch jacks for keying and output
- Keys grid block and solid state rigs
- WIRED AND TESTED FULLY GUARANTEED—LESS BATTERY



Features:
- Advanced CMOS message memory
- Two (50 char. each) message storage
- Repeat function
- Records at any speed—plays back at any speed
- Longer message capacity Example: send CQ CQ CQ DX de WB2YJM WB2YJM K—then play second message on contact—de WB2YJM QSL NY NY 579 579 Paul Paul K
- Use for daily QSOs or contests

PLUS:
- State-of-the-art CMOS keyer
- Self completing dots and dashes
- Both dot and dash memory
- Iambic keying with any squeeze paddle
- 5-50 wpm
- Speed, volume, tone, tune and weight controls
- Sidetone and speaker
- Low current drain CMOS battery operation—portable
- Deluxe quarter inch jacks for keying and output
- Keys grid block and solid state rigs
- WIRED AND TESTED FULLY GUARANTEED—LESS BATTERY

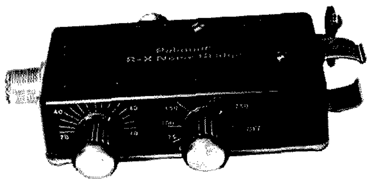
R-X Noise Bridge



- **Learn the truth about your your antenna.**
- **Find its resonant fequency.**
- **Adjust it to your operating frequency quickly and easily.**

If there is one place in your station where you cannot risk uncertain results it is in your antenna.

The Palomar Engineers R-X Noise Bridge tells you if your antenna is resonant or not and, if it is not, whether it is too long or too short. All this in one measurement reading. And it works just as well with ham-band-only receivers as with general coverage equipment because it gives perfect null readings even when the antenna is not resonant. It gives resistance and reactance readings on dipoles, inverted Vees, quads, beams, multiband trap dipoles and verticals. No station is complete without this up-to-date instrument.

Why work in the dark? Your SWR meter or your resistance noise bridge tells only half the story. Get the instrument that really works, the Palomar Engineers R-X Noise Bridge. Use it to check your antennas from 1 to 100 MHz. And use it in your shack to adjust resonant frequencies of both series and parallel tuned circuits. Works better than a dip meter and costs a lot less.

The price is $59.95 in the U.S. and Canada. Add $3.00 shipping/handling. California residents add sales tax.

master charge VISA

Send for FREE catalog describing the R-X Noise Bridge and our complete line of SWR Meters, Preamplifiers, Toroids, Baluns, Tuners, VLF Converters, Loop Antennas and Keyers.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

BREAKING LOOSE

One of the difficulties about trying to explain amateur radio to friends is the wide variety of hobbies which make it up. The general public, if it has any image of amateur radio at all, tends to think of it as a bunch of kids talking to people around the world from their attic or cellar ham stations. In some respects, this isn't far short of the mark... we *are* kids, having one hell of a lot of fun. And a fair percentage of us are in there working DX.

Not so well known to the public are the tens of thousands of us talking with each other through repeaters from our mobile stations or hand-held rigs. And virtually unknown are the thousands of us who are mixing computers and amateur radio over the air, working via ASCII, packet radio, and RTTY, or are into such fascinating aspects as SSTV, facsimile, satellite communications, low-band DXing, VHF DXing, meteor bounce, aurora bounce, and so on.

Indeed, I'd venture to guess that there are tens of thousands of hams who are missing out on much of the fun and value of amateur radio just because they are off stuck in some corner, perhaps spending the remaining days of their lives rag-chewing on 75m or being alternate net control on some nightly net.

The monthly infusion of excitement from *73* helps to break up these gradually hardening patterns of life. By publishing articles on the fun of some new aspect, it gets dozens more broken loose every month. You can help with this process, making amateur radio more fun and of more value to both hams and our country. You can do this by writing articles on an activity you are involved with which you think should be enjoyed by more amateurs. You can do it by trying out some new aspect of the hobby and talking to your friends about it... talking it up at the ham club.

Building some new gadget is a ball. Not only is it a challenge to do, but when you get through you have something to show to your family and ham friends. No, you don't want to try to build a synthesized sideband transceiver from scratch. But you might want to try your hand at something easier, such as one of the small construction projects in *73* each month.

Over 60,000 hams have expanded their interest in amateur radio to include computers, with the result that a growing number are getting on the air and making high-speed computer-aided CW contacts, computer-run RTTY contacts, and so on. Further, a surprising number have taken their newfound computer interest and escalated it into a small business... with many going from tiny part-time efforts to million-dollar-size businesses.

The world is heading toward a major communications change. This means that amateurs have an opportunity to be in the vanguard of the change... or, as for the last twenty years, they can hang back, keeping alive the spirit of the 30s more than the 80s. It is surprising, and disappointing to some, how few real changes have been made in the last fifty years of hamming. Oh, the time was when new modes of communications were invented and pioneered by hams. We did a pretty good job of this with sideband thirty years ago and with FM and repeaters fifteen years ago. But even these technology changes have made little impact on the old-time ham... so far. Indeed, a ham going through time from 1933 to 1983 and tuning the ham bands would find it difficult to tell that 50 years has passed.

When one looks at the possibilities which we have with the technology already at our command and then looks ahead a few years to see what we might be able to develop, the prospects are exciting. Repeaters are okay, buy why not start linking them up via remote controls so they can relay, probably via 450 MHz or even 1200 MHz, so longer-range contacts can be made easily? And how about setting up some low-band links via repeaters? Now that the FCC says they are going to stop restricting our experimenting, it is time for us to get cracking.

The day isn't far off, if we get moving, when we will be able to have local repeaters route contacts via other central repeaters, then up via a satellite such as Telstar using space commercial channels and back down again anywhere in the country, again routing from a central satellite link to a local repeater, and out. Granted, we won't be able to do a lot of voice communicating via such links, but once we get the hang of RTTY and ASCII communications, we'll be able to zip messages around almost anywhere in the world.

The new message-boy satellite will get us used to sending messages up to a repeater, having them stored there for drop as the satellite circles to some other part of the world... picking up traffic for us perhaps over Bangkok and dumping the message as the satellite goes over North America again a few hours later.

Sure, you're going to have to start getting some new equipment. You're going to have to start building some of it, too. And the secret to all of this is in your monthly magazine, which will keep you in touch with the other people experimenting with new techniques and services. I really feel sorry for the ham who is so dead that he doesn't get *any* ham magazines... and would you believe that over half of the licensed hams read no ham magazines at all? If you know someone like this, try to get an issue of *73* into his hands, even if only overnight. Let him see the wide variety of simple construction projects which he could have fun with... the excitement of getting onto RTTY or slow scan. A brain without stimulation turns to garbage... check the bands and see if I'm not right.

Talk up the magazines over the air; get fellow hams into reading 'em. Sure, the magazines seem expensive at $25 per year, but put that into perspective. Remember that deluxe cars were only $500 a few years ago. Modern presses have kept the cost of magazines down substantially, with the main cost these days being the postage, which has gone up beyond belief.

As a continuing source of state-of-the-art information, there is no substitute for magazines such as *73*. If you want a lot of club news with a few technical articles, you've got *QST*. If you want contest info, you've got *CQ*. If you're hot for super-complicated contruction projects, there's *HR*. For articles on lots of gadgets you can build, info on the latest in RTTY, ASCII, SSTV, and other new developments, thorough coverage of FM and repeaters, and also the best international coverage, there's *73*. The main aim of *73* is to make amateur radio more fun.

THE ASCII INRUSH?

Considering the growing number of contraptions to interface computers and ham rigs, we may be able to get some interest in joining the ham ranks by computerists. Now, with computers costing under $50 (the Timex TS-1000 is reported to be $59.95 at Osco Drugs, less a $15 Timex rebate) and with a projected sale of well over two million computers for 1983, we may be developing a large untapped source of hams who will go for a digital communications system.

Tell you what, if you'll start writing some articles on the amateur radio use of computers and submitting them for publication, I think I can get our computer magazine editors to give this movement a push. Articles on using the TRS-80 systems will obviously be routed into *80 Micro*. Those which are Apple-based will go to *inCider*, our new Apple magazine. Those which are based on other systems will probably be aimed at *Microcomputing*.

By the way, in case you're interested, *inCider* got off to a fine start with the January issue and has, so far, been growing even faster than *80 Micro* did when we launched it back in 1980. *80* is running 400-500 pages a month these days and is still growing nicely, with around 300,000 regular readers. By the time we add the readers of the three magazines together, we reach about 700,000 computerists each month. If we only interest 10% of them in trying amateur radio, that'll be the biggest jump in new hams in over twenty years.

Mind you, I'm not looking for a one-shot promotion. When we started pushing FM and repeaters, we didn't get that moving with one or two articles. It took hundreds of them, backed up with books, FM symposiums, a monthly repeater newsletter, and so on. So we'll be needing articles on the fun of ASCII communications, articles on the use of all of the gadgets now on the market, construction projects for rolling your own, words on how to do digital via OSCAR, and info on how to set up repeaters so they can handle a second digital channel as well as voice relaying, how packet radio works, how to use the coming messenger-boy satellite, and so on.

We need articles on using all of the low-end computers for ham communications. There's the VIC, the T. I. 99/2, 99/4A, and 40, the Timex TS-1000 and new 2000, the Atari 400, 800, 1200, and coming 600, the Jupiter

QSL OF THE MONTH

This month's winning QSL comes from Jim Kirkreit K7YLM in Tacoma WA. The munchkin curled up on top of the radio is a caricature of Jim, and it was originally a pen-and-ink drawing by an inmate incarcerated at the federal prison where Jim worked. The drawing depicts "what he thought I looked like when I was transmitting," Jim said. But, "I must be honest," he added, "I usually don't operate while sitting on top of the rig."

If you think your QSL card is a winner, put it in an envelope with your choice of a book from *73*'s Radio Bookshop and send it to *73*, Pine Street, Peterborough NH 03458, Attn: QSL of the Month. Entries without an envelope or book choice will not be considered.

Ace, the Panasonic JR-200, the two new Sanyo computers, and so on. Experimenters will undoubtedly make improvements on the commercially-available interfaces, which means more articles.

Then we need to get cracking on 1200 baud and higher speeds, working out the kinks of high-speed digital communications through QRM, QRN, fading, and so on. We need to seriously tackle the problem of error-correcting. If we are going to do any relaying of digital communications, each step in the relay must be error-corrected before the relay is continued. And we're looking at developing systems which will perhaps relay from a transceiving keyboard to a repeater direct to a second party, or perhaps via a relaying system through several more repeaters, or even a satellite or a low-band link. . . each step with error-correcting. Yes, we need a lot of experimenting. I think we're going to have more fun with all of this than anything else we've ever done in amateur radio.

In the meantime, let's start with what we've got and get going. Get your computers communicating over the air and write articles. . . which in turn will get more people playing around and incite manufacturers to turn out more interfaces for us. The secret to getting anything moving is to get the word spread around. Remember that FM and repeaters were being enjoyed by only a few hundred hams until I started making a big deal about it in *73*, and after that we managed to develop a whole industry around this activity. With computers and amateur radio I think we can get new blood into our hobby and have more fun than we have had in years.

WHAT COMPUTER?

A recent poll of *73* readers showed that over 37% already have some sort of microcomputer and about 80% are interested in 'em. The question which gets asked several times a day of any computer owner by friends is, "What computer should I get?"

With almost 300 different makes of desktop computers, one would think that a truly objective answer to that question would be impossible. After all, with over 400 different computer models being made, how can any one person know what really is best. . . and from what viewpoint?

Fortunately, the answer isn't anywhere near as complex as it would at first appear. Oh, I suppose if someone was interested in buying a small computer for one specific application and was absolutely positive that it wouldn't be used for anything else, the choice could get complicated. But the facts of life are clear: No matter what application someone has in mind when they get a computer, it isn't long before the uses of the system are expanding almost beyond control.

Perhaps I can state one basic rule of the computer field: Whatever you buy, it will merely be the beginning of a long string of purchases as you expand your system. There is no known limit to this.

But to get back to an attempt to answer the question of what computer system it would be best for you to buy. Before I name names, which I will, I've been around the darned things ever since they were invented, so I have a fair perspective on 'em. . . one which is not particularly colored by self-interest, though it may not give that impression.

The value of a computer system lies in three factors. Each of the three, I regret to say, appears to be of equal importance. They are, simply, the hardware, the software, and the instructions. Well, big deal, you may say. Yep, it is, and you'd better read on before chalking that up to just one more platitude.

To give a horrible example before I go into details on what I'm writing about, a very nice little portable computer arrived a few weeks ago for review by our staff. We got it out to a reviewer and after he had finished with his report, I asked to have the computer brought to my office so I might have a chance to work with it. It looked great and came with some powerful programs ready to use.

A couple of hours later I was almost screaming in frustration. I couldn't get *anything* to run on the damned thing. Oh, the disks would start up and the prompt appear on the screen, but nothing I could discover would get a program into operation. And, yes, I tried to use the instruction book. What a terror that was! I've been around microcomputers for seven years now and I couldn't make anything out of the instructions. Nothing anywhere in the manual explained how to put in a disk and get a program running.

Experienced computerists will be provoked with me for my anger. . . pointing out that *most* computers come with these big fat, almost useless books of instructions. The manuals are filled with computer scientist jargon, not simple how-to-do-it information. The sorry fact is that few equipment manufacturers provide much of value in the way of operating instructions for their gear. . . and that goes for software firms, too. This may help to explain why system-specific magazines such as our *80 Micro* grow so rapidly in circulation and size when they are announced.

Let me put this bluntly: If you opt for a computer system which is *not* supported by a magazine, you are going to lose much of the value of having a computer. The system-specific magazines serve several purposes, all of importance to you. First, they provide you with a continuing source of information from other users on how to get the most from your computer. In that respect, the magazine is like an enormous users group. Until you start getting one of these magazines, you may find it difficult to understand how much there is to be learned about your computer and how important it is for you to get this constant update.

A second value of such magazines lies in their use as a medium for the manufacturers of accessories, the publishers of programs, and the publishers of information about the system to reach you with their wares. Many of these firms are small and, without such a magazine, they would never even have a chance to get started since the several thousand computer stores have no way to seriously deal with hundreds upon hundreds of small suppliers. Being small, you'll often find some remarkable bargains via these firms.

A third benefit of your system-specific magazines lies in the wealth of programs which are published in each issue. *80 Micro* often has 20-40 programs listed in an issue, ranging from home programs to business, educational, simulations, scientific, and so on. These are available from some magazines in machine-readable form so you don't even have to sit there for two weeks typing in the listings. We have *Load 80* for *80 Micro* readers, either on cassette or disk.

Another benefit, and not a little one, lies in the discounts you'll find in these magazines. The buyer of a Radio Shack TRS-80 Model III system can often save up to $1,000 on a complete system by buying through some of the discount houses advertising in *80 Micro*. Even on one of the color computers, you may be able to save around $400 on a system, according to the editors of our new magazine, *HOT CoCo*, due out soon.

If you do decide to get a system which is not supported by a healthy system-specific magazine, you are going to have to make do with a minimum of help, support products, software, and discounts. Good luck, buddy. It's a route I would never recommend to anyone.

Okay, what systems are supported by such magazines? Well, there are several magazines for the TRS-80 computers, with *80 Micro* being the largest and best read by a wide margin, running from 400-600 pages a month. The Apple system is supported by several magazines, with our new one, *inCider*, already having the largest paid circulation in the field. That's self-serving, granted, but it is also the plain truth.

The IBM system is supported by a growing number of magazines, starting with *PC*. This is almost entirely a business-oriented system, so I'm not sure how much you may want to horse around with it. The Apple and TRS-80 have turned out to be of much greater interest to hobbyists, and so we are seeing a wider range of interesting uses. Still, the IBM does have strong magazine support. Beyond that you are in shallow waters. Commodore has effectively discouraged third-party publishers from doing anything for their computers by putting out their own in-house magazines, but these are so self-serving that they are of little value. Ditto most of the other such efforts. Osborne announced his own magazine supporting his system, but I've seen nothing beyond the first issue, so perhaps that fell through. They would do better to encourage a third-party publisher than to do it themselves. Apple has their own magazine, but slick as it is, it doesn't do much to help the Apple owner. Ditto the Radio Shack in-house magazine, which seldom has anything of much interest or value, or much material, and positively no discount ads.

Are you beginning to get the idea that this is coming down to a recommendation that newcomers to computers can expect to get into a lot of trouble if they go any route other than Apple or the TRS-80? Well, that's the way it seems to me. Remember, too, that because we have had these magazines providing communications between small firms and the users, we've had an incredible number of good programs developed. Firms don't put a lot of money into writing and publishing programs for systems where it is hard to reach the users.

The Timex-1000 computer is so cheap it is ridiculous. . . and it *is* a good computer. But the instructions which come with it will drive you up the wall, and good luck getting any help from any other source. With the system selling through a nearby drug chain for $59 and a factory $15 rebate, one could hardly find a cheaper computer. It's a marvel at that price, but only if you know what you are doing and don't mind the lack of instructions.

The VIC-20 is down to $150 via mail order, I see, though I think the firm selling it at that price may be connected with Commodore in some way. But even at that price, and considering the value of the computer, unless Commodore decides to get out of the publishing business and work with a third-

ARTICLES WANTED

For *73*, we need articles on: RTTY/ASCII construction projects, mods of commercial RTTY/ ASCII interfaces, computer ham applications, error-correcting developments, packet radio equipment and activities, digital communications via ham satellites, advanced repeater services and equipment. For our computer magazines, we need articles on the use of ham bands for computer communications.

Construct This Classic Transmitter

From the era of the tube comes this ageless design, runner-up in 73's Home-Brew II Contest. It's perfect for a first project or as a backup rig.

There are only two reasons you'll want to copy this little rig: It won't cost much and it's a lot of fun to build and use. This one-tube, crystal-controlled, 15-Watt oscillator is a copy of the type of transmitter built by thousands of hams in the post-WWII years as a first rig. Operating on 80 and 40 meters, it will load into practically anything and can provide solid contacts over distances of up to several hundred miles and even an occasional bit of real DX.

Collecting the parts and building the unit is half the fun. As can be seen in the photographs, the construction technique (true to the nature of the originals) could best be called free-style breadboard! With the exception of the tube and two old-style broadcast receiver tuning capacitors, most of the parts came from a discarded black and white TV chassis. While it's conceivable that all of the parts could be purchased new (for about $30), you'd be making a mistake if you did so. This is a low-pressure, easygoing junk box project, a strictly-for-fun test of ingenuity. Rummage around in the basement, ask your neighbors about their attics, visit your fellow hams—and above all, enjoy yourself!

Parts are cheap at Joe Ham's Curbside Parts Emporium! This TV chassis provided 80% of the transmitter's components.

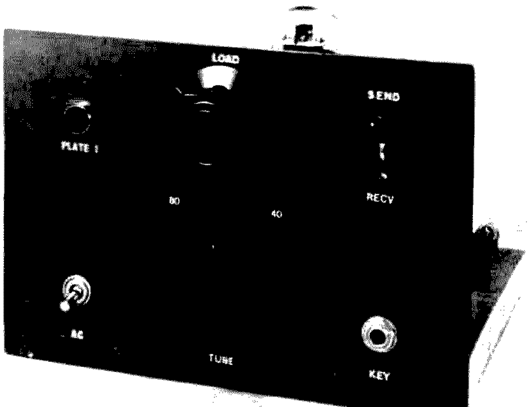
A Touch of History

In the 1950s, it was much more common than it is today for a ham to build some major piece of station equipment. One reason is that the surplus market was flooded with inexpensive radio parts. Another is that up-to-date ham equipment, particularly for transmitting, was a lot simpler then. Crystal frequency control was common, and a CW transmitter, even one in the several-hundred-Watt class, was often just an oscillator driving one or maybe two paralleled output tubes. With no vfo, mixers, gang tuning, or even bandswitching (use plug-in coils!), the transmitter could be a pretty simple affair.

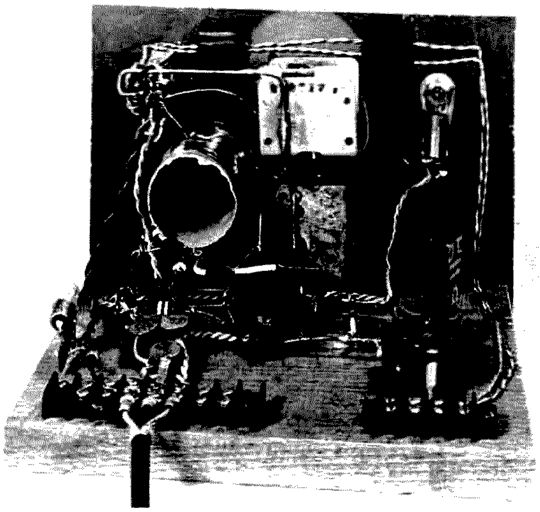
When the Novice license was created in 1951, it required the use of a crystal-controlled transmitter of less than 75 Watts input power and consequently the one-stage power oscillator became a popular home-brew item. The output obtainable from a crystal oscillator is limited primarily by the power sensitivity of the tube used and the amount of rf current the crystal can handle before fracturing. Some of those war-surplus crystals were pretty rugged, but even the smaller FT-243 quartz blanks worked fine with the sensitive tubes being developed for the postwar radio and TV boom. Single-tube oscillators soon were common on the 80- and 40-meter Novice bands, and gradually some really memorable designs emerged from the crowd.

One of the cheapest ham transmitters ever sold came out in 1960—the Ameco ATC-1, a one-tube 6V6 oscillator selling in kit form for less than $20. It was rated at a full 15 Watts input on 80 and 40 and came complete with all tubes, a crystal, and even a punched chassis! Perhaps the cleverest example of cheap and simple transmitter construction is a design from the 1950 *ARRL Handbook* which takes full advantage of a feature then common in commercial receivers. Perhaps as a holdover from the days when vacuum tubes were very expensive, many of the receivers of that time had the audio for driving headphones taken from a low-level stage so that the big

2



The front panel is dominated by the tune and load controls. The wide-range-output circuit will load power into practically anything.



Behind the attractive front panel the layout is true breadboard. Not pretty, but simple and effective. The single tube plugs into the center socket; the two on the right are for crystals. Wires taped across the top of the panel are receiver antenna and power leads.

audio-output amplifier was really used only with the speaker.

Once resigned to using the headphones only, the amateur could unplug the unused audio tube and build his transmitter around it —perhaps using some handy orange-crate slats for a chassis. A short cable and an octal plug fashioned from the base of a carefully-broken tube would then allow the transmitter to draw its filament and B+ power from the receiver's power supply: out of the same socket that previously held the output tube! No whining in those days about the high cost of ham equipment!

Noncritical Circuit— Easy To Copy

The "1950s Special" described here runs between 10 and 30 Watts input depending upon the tube type and power-supply voltage used. Output power ranges from 3 to 15 Watts, and that's plenty for making lots of solid contacts, particularly if a good antenna system is used. The circuit shown in Fig. 1 will work with a 6L6, 6V6, or 6K6 tube. While those tube types are common (they were popular for use in the audio stages of TVs, radios, and phonographs), the circuit is so noncritical that just about any power pentode in the 10-to-20-Watt class will work if the socket wiring is arranged to suit the tube pinout.

The oscillator itself is the grid-plate circuit familiar to anyone who has studied for the FCC amateur exam. The output circuit is a pi-network chosen for its ability to match a wide range of loads and simultaneously provide a high amount of harmonic rejection. Unlike the modern "no tune-up," solid-state equipment, this transmitter will load up into almost anything—even the proverbial damp string. A single-pole double-position slide switch adjusts the pi-net for either

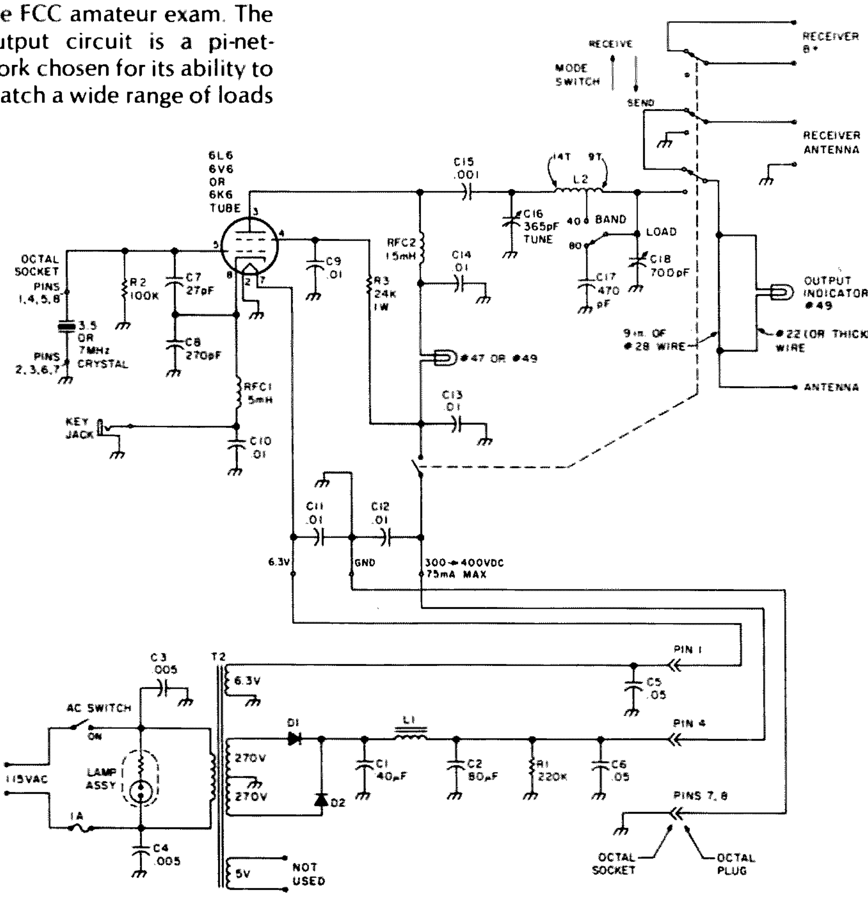


Fig. 1. Schematic of the one-tube transmitter and its power supply.

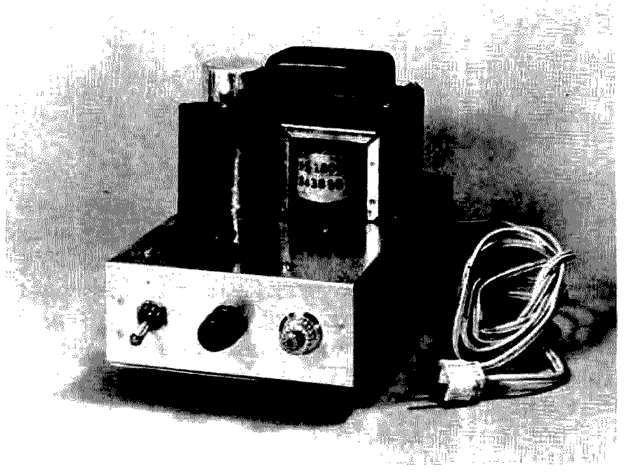
(3)



The separate power supply is built almost completely from TV-set components. Neatly built, it doubles as a useful general-purpose power supply.

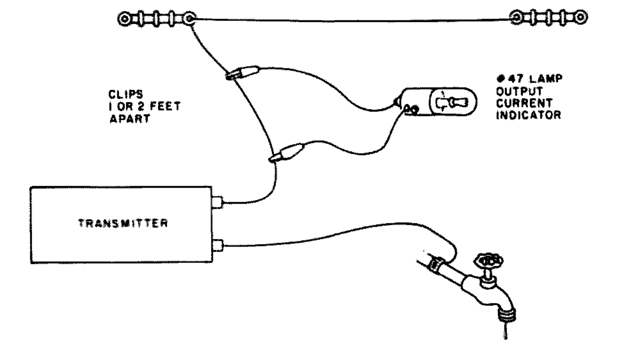


Fig. 2. Poor ham's variable rf ammeter as used with endfed antenna system.

80- or 40-meter operation, and a panel lamp in series with the plate power lead makes a cheap and effective replacement for the usual milliammeter.

In a similar vein, a second lamp is used as an output-power indicator in a version of the "Poor Ham's Variable Rf Ammeter" (see Fig. 2). This circuit is a real classic—the bulb is shunted across a portion of the antenna lead with the distance between clips determining the drive to the light. This surprisingly sensitive indicator is thus easily adjustable for a wide range of impedance and power levels. The dimensions given in Fig. 1 are suitable for loads of around 50 Ohms, and the more flexible arrangement shown in Fig. 2 can be used if necessary with random-length endfed antennas.

The only unnecessary frill added to the circuit is a 4PDT lever switch used to control the transmit-receive switching of the transmitter and its companion one-tube receiver (more on that later). The ac switch on the front panel is not used, for reasons explained shortly.

The power supply is built as a separate unit. This isn't strictly necessary, but I wanted to build the transmitter on a real breadboard, and for safety's sake an enclosed metal chassis is required for the power supply. Another important consideration is that the supply can then be used on other projects in the future.

One nice feature of the older TV receivers is that they usually have a power transformer instead of the series filament string "ac-dc" type of setup. These transformers provide for 6-volt filaments and about 275 volts on either side of a center tap—perfect for a small transmitter. If you have a choice, look for a black and white set because of its smaller (and lighter) transformer. Some of the older color sets have power transformers more suitable for 500-Watt linears than 15-Watt oscillators! In any case, the power transformer and filter components of my supply all came from Joe Ham's Curbside Parts Emporium (see photograph).

Real historical honesty would require the use of a vacuum rectifier tube, but I cheated slightly and used a more modern pair of TV-set silicon diodes; they are smaller and cooler than the tube. Feel free to use whatever you have or can get the easiest, however. After all, that's what this project is all about.

What About TVI?

Old-timers who remember breadboard-style transmitter construction also will remember the TVI problems which contributed to the use of the metal chassis, pi-networks, and coaxial cable. There are two reasons why TVI is not a big problem with this transmitter: (1) Its low input power keeps any harmonics that much weaker to begin with, and (2) the pi-network does an excellent job of filtering the antenna output. While the signal reaching the antenna is pretty clean, the grid circuit of the oscillator is rich in harmonics and direct radiation from the transmitter wiring may be a problem. In my case, the transmitter, when operating on 40 meters with the 6L6, produces noticeable cross-hatching on channel 5 when the TV and transmitter are in the same room. The sets next door are completely unaffected, as is my own TV when it's moved to the garage 75 feet behind the house.

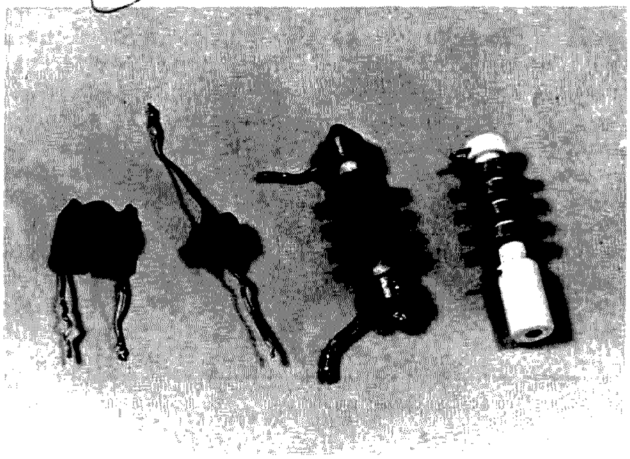
Operation on 80 meters is TVI-free, and several simple precautions can reduce the local 40-meter problem. Using the lower-power 6V6 or 6K6 tubes helps considerably. A proper balanced dipole is better than a random-length endfed wire antenna since less rf gets accidentally coupled into the house wiring, plumbing, etc. Harmonic generation and radiation also are reduced significantly if the plate-tuning control is adjusted slightly to the low-frequency side of the peak-output point.

TVI is an unsavory subject to bring up in a transmitter construction article, but the issue should be faced. Interference is not a real problem with my set, and I took no particular precautions against it during construction. If you live in a crowded apartment complex, however, it might be wise to build the transmitter on a metal chassis. Placing all the grid-circuit components under the chassis and then screwing on a metal bottom plate will go a long way towards preventing even the minor TVI I observed.

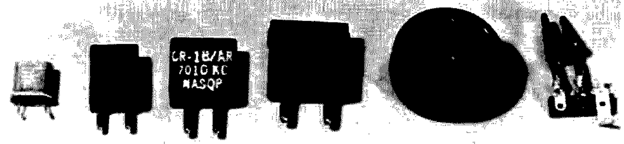
Construction Tips

I built my transmitter on a 7" × 8¼" pine board which is ⅞" thick. A 6" × 8½" piece of 1/16" aluminum serves as the front panel and mounting support for many of the components. The several tube sockets are screwed to the board using ¼"-long wood, plastic, or metal spacers as standoffs. Newer hams may not know the trick of using an octal socket for crystals: The popular FT-243 holders will plug in nicely. I wired my socket as shown in Fig. 1 so that a crystal can be plugged in any pair of holes and still make proper electrical contact. Some of my crystals are real old-timers and have oddly-sized pins. To accommodate these, I also added the

4



The standard 2.5-mH rf chokes (the right-hand pair) are nice to use if you can get them. Several TV-style chokes (left-hand pair) in series will work just as well in this low-power circuit.



Second-hand crystals come in many sizes—all of them useful! Many hams prefer the standard FT-243 holders (second from left) which means that the others are cheaper to buy. The "universal crystal pin-grabber" (far right) will hold any of them.

old-style 6-pin tube socket visible in the photograph. In a pinch, even a *real* crystal socket would work!

Much of the rf circuit and ground wiring is done with thick copper house wire with the insulation stripped off. Many of the smaller components are supported simply by soldering them to these heavier bus wires. Use insulated wire for the high-voltage-dc circuits though, and make an effort to minimize the amount of exposed conductor in the plate and screen circuits. *Be careful to choose a socket for the panel lamp which has both contacts insulated from ground.* Some sockets automatically ground one side of the bulb—a real health risk in this application. My lamp socket has a pretty red jewel, but, to be honest, I usually look at the bulb by peeking over the top of the panel.

The power and antenna wires connect to the transmitter through an old-style barrier strip mounted on the rear of the board. Those wires could just as well be soldered to several salvaged TV terminal strips if you don't have the screw-type connector. My transmitter has a panel-mounted ac-power switch to control the external power supply. This isn't a good idea because the 115 volts gets exposed on the rear terminal strip. I never used the switch for anything, and the front-panel space would have been better utilized as a mounting place for the crystal socket. That also would remove the temptation to reach behind the panel and change crystals while the B+ is applied.

For the sake of historical authenticity, the plate-circuit pi-network coil is wound on a cardboard tube salvaged from a roll of toilet paper. These tubes aren't as sturdy as they used to be, and it was necessary to give this one several heavy coats of varnish before it was stiff enough to take the winding tension of the wire without collapsing. The coil requires about 12 feet of #20 wire. Solid hookup wire is ideal, but wire salvaged from the secondary of an audio-output transformer or deflection yoke will work fine, too. Of course, just about any of the commercial air-wound coil stock could be used, but there is a lot to be said for the thrill of building as much as possible of this rig with your own hands!

To wind the coil, first punch several small holes about ¼" apart near each end of a 3" section of the cardboard tube. Clamp one end of the length of wire in a vise and stretch the copper out by pulling on the far end to get it straight and kink-free. Thread the end through one pair of holes on the form leaving a 6" tail for the coil lead and then wind the 23 turns on the form as you walk towards the vise. If the coil is wound too loosely it will not hold its shape; too tightly, and the cardboard tube will collapse. After winding, thread the end wire through the other pair of holes and then spread the turns out to evenly cover about two inches of the form. When it looks as neat as possible, the turns can be fixed in place by running several beads of model cement down the length of the wiring. At first, I mounted the coil in the transmitter using only the leads for support. That wasn't stiff enough with the soft wire I had used, so I added a few drops of glue to steady it against the back of the front panel.

The plate- and load-tuning capacitors were salvaged from old broadcast receivers. The tuning capacitor is a single 365-pF section while the loading capacitor has two sections in parallel to total about 700 pF. When the bandswitch is in the 80-meter position, an additional 470 pF is added to the loading capacitor. That won't be necessary if you can scare up a tuning capacitor with three or more sections totaling 1000 pF or more.

Old-fashioned pi-wound rf chokes are a rare item these days, but fortunately a suitable substitute can be found in many old TV sets. The TV chassis I salvaged for parts had four small single-section chokes in it. Their inductance values ranged from .5 to .8 mH, so several placed in series make a good replacement for the old 2.5-mH standard. The transmitter requires two chokes, and at first I used two 2.5-mH units from my junk box. That worked fine, but I found by experiment that the transmitter worked just as well if a single TV choke was used in the cathode circuit and the three remaining units were series connected in the plate circuit.

The biggest problem in collecting parts for this little transmitter is finding some crystals, and the only economical solution is to get them from other hams. It's been years since low-band crystal control was popular, but hams rarely throw anything away. Any amateur flea market is likely to turn up someone with a box full of ham-band crystals priced at not more than fifty cents apiece. Twenty-five cents is a good price, but try offering the fellow a buck and a half for the whole box. If the flea market doesn't pan out, talk to some of the older fellows in the local club. Don't be afraid to buy old-style crystals in odd-looking holders (see photograph); they work

5

fine and make interesting additions to your collection of rocks.

No sockets for them? Try old-style tube sockets or—as a last resort—use a couple of alligator clips on the end of some stiff pieces of wire and build a "universal crystal pin-grabber" into your transmitter. As a final solution to the crystal procurement problem, you can always use the 3.579-MHz burst crystal from a junked color TV set. The biggest trouble there is that every color set in the neighborhood is radiating energy on that frequency and you may have to put up with a lot of unnecessary interference in your receiver.

I built this transmitter for use with the one-tube regenerative receiver described in "The Tube Returns" (*73*, December, 1982). To make combined operation easier, the transmitter send-receive switch incorporates some features which aren't strictly necessary. The minimum requirement is for a transmit-standby switch which opens the transmitter B+ line on standby. Having an old 4PDT lever switch, I wired it so that, in addition, it (1) connects the antenna to the receiver on Receive, (2) shorts the receiver antenna input on Transmit, and (3) opens the receiver B+ line on Transmit. Depending upon your needs and resources, you can add any or all of those extra functions.

The front panel was finished off with gray paint and press-on lettering—very unauthentic for a 1955 replica. My excuse is that the salvaged panel was already painted and scratched up from its previous use. Don't feel that you have to apologize to anyone if your version features unfinished aluminum and penciled-on control labels. Many of the original one-tubers didn't even *have* a front-panel—just parts mounted on a board or inverted cake-pan chassis!

The separate power supply is pretty conventional in circuit and layout. My collection of parts fits nicely on a 5″×9″×2″ chassis. The power transformer, filter capacitors, choke, bypass capacitors, and miscellaneous hardware were all salvaged from the TV chassis shown in the photograph. A full-wave rectifier using two TV power-supply diodes is mounted on a terminal strip under the chassis. Any diodes rated at more than 800 volts and 1 Amp will work fine, as will any of the common rectifier tubes (5Y3, 5Z3, 5V4, 5U4, 5R4, etc.). A bottom plate covers the under-chassis wiring for safety and neatness.

If you have trouble finding a real chassis, you can always use an inverted baking pan—the bread-pan size should be about right. For a bottom cover use a piece of board cut to fit tightly just

Parts List

Preferred values are shown on the schematic; a usable range of substitute values is given here.

C1, C2	20 or more uF at 350 or more working volts
C3, C4	.001 to .01 uF, 400 V or more
C5, C6	.001 to .1 uF, 400 V or more
C7	10 to 56 pF
C8	220 to 390 pF
C9-C14	.001 to .05 uF, 400 V or more
C15	.001 to .01, 600 V or more
C16	Single section of broadcast variable, 365 pF
C17	390 to 680 pF
C18	2 or more paralleled sections of broadcast variable, 700 pF or more total
D1, D2	1 Amp or more, 800 or more piv (TV rectifier diodes)
R1	220k to 470k, 1/2 Watt
R2	100k to 470k, 1/2 Watt
R3	22k to 39k, 1 Watt (may be 2 parallel 1/2-Watt resistors)
L1	TV power-supply choke (Typically 1 H at 350 mA) or any choke rated 1 H or more at 75 mA or more
L2	23 turns, 2″ long, 1-5/8″ diameter, #24 or heavier wire, tapped at 9 turns. Turns and dimensions may vary by +/− 20%
RFC1	.5 to 2.5 mH, TV set rf chokes in series
RFC2	1.5 to 2.5 mH, TV set rf chokes in series
T1	TV power-supply transformer. 220 to 325 volts ac on each side of center tap at 50 mA or more, and 6.3 volts at 1 Amp or more

BUYING PARTS

Readers living in truly remote parts of the US or on isolated Pacific atolls may genuinely not be able to scrounge parts, so here is a list of mail-order suppliers for the major transmitter components:

- **Fair Radio Sales, 1016 E. Eureka St., Lima OH 45802 (1982 Catalog).**

Power transformer	cat. no. TB1RX03LB/FGC-29	$5.95
Filter choke	cat. no. TF1RX04LB/FGC-29	3.95
6L6 tube (unused! but not new)		3.00
Octal sockets (2-hole mounting, 3@35¢)		1.05
		$13.95

- **John Meshna and Sons, Inc., PO Box 62, East Lynn MA 01904 (Catalog #23, Spring 1982).**

3 broadcast tuning caps (ask for AM style)	cat. no. SP-117	$1.00
40-meter crystal (choose 1 freq: 7.025, 7.050, 7.075)		1.00
10 1-mH rf chokes		1.00
Filter capacitor	cat. no. MC-6	.25
6 slide switches (SPDT)	cat. no. SW-103	1.00
10 ceramic disc caps (ask for eight .015 1 kV, one 22 pF, and one 270 pF)		1.00
3 key jacks	cat. no. H-38	1.00
3-Amp, 1000-piv diodes (2@45¢ each)		.90
3 indicating fuseholders	cat. no. SP-30-21	1.00
		$8.15

Meshna has a $10 minimum order; you might want to write for their catalog first and see what else looks good.

- **Radio Shack (1982 catalog).**

Barrier strip	274-670	$1.39
Knobs (2)	274-407	1.29
Alligator clips	270-380	1.19
1.5-A fuses (3)	270-1274	.59
470k, 1/2-W resistors	271-042	.19
47k, 1/2-W resistors (parallel for R3)	271-042	.19
#47 lamps (2)	272-1110	.69
6-V, 60-mA lamps	272-1144	.99
		$6.52

Total project cost: $13.95 + 8.15 + 6.52 = $28.62. With a little effort put into scrounging parts, the actual cost should be something under five dollars. If your immediate circle of friends fails to produce a suitable TV set, remember that many supermarkets have bulletin boards where "want" notices can be posted at no cost. And don't overlook the possibility of putting a want ad in the local newspaper. Something like this should produce results: Old TV??—I'll Haul it Away Free! Experimenter desires donations of old working or nonworking TVs and radios for educational project. Let me help clean your cellar!

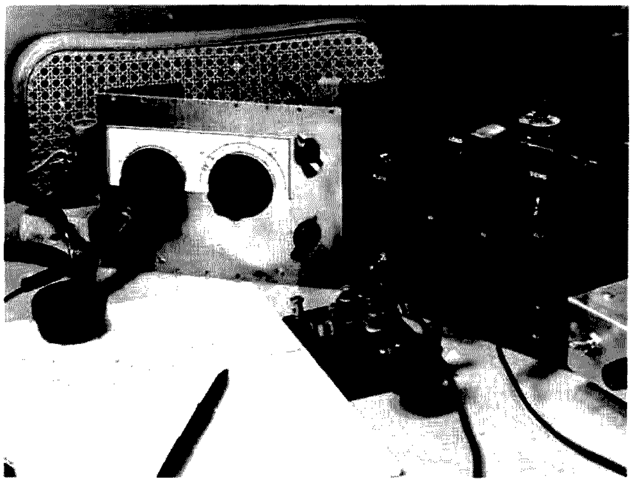
6

inside the bottom opening and secured in place with wood screws. Don't forget to include an ac line fuse even if you have to buy the holder. My supply is good for 375 volts at 200 mA or so, and 6.3 volts at 3 or 4 Amps. The transmitter will draw at most 75 mA of B+ current and less than an Amp at 6.3 volts.

Tuning Up

Before actually discussing tune-up, let's discuss safety. There are high voltages exposed on the components and wiring of this transmitter. That's easy to forget in these days of transistor equipment and 12-volt power supplies. Remember that the high voltage is there, and remember that the filter capacitors will stay charged for some time after the ac is turned off. Watch your fingers! Watch out also for small children or pets when you're using this rig. This little transmitter is a lot of fun to use but don't let an accident zap your enjoyment.

With only two controls, tuning up doesn't take much time. The procedure is basically the dip-and-load operation used with most tube-type transmitters. Connect an antenna or dummy load (a 7- or 10-Watt, 115-volt bulb works fine as a dummy), plug in a key and crystal, and turn on the power. Eighty-meter crystals will work on 80 or 40 by the way, but the output power is cut almost in half when the transmitter is doubling, so 40-meter crystals are recommended for that band. Set the loading capacitor to maximum capacitance, hit the key, and rotate the tuning capacitor until a dip in plate current is reached somewhere around the middle of the capacitor's range. As always, minimum plate current (as indicated by a drop in the brightness of the plate-current indicator bulb) corresponds with maximum power output.



The complete two-tube station, ready for action. The 6SN7 receiver was described in the December, 1982, issue of 73. This simple and inexpensive setup can provide solid contacts over hundreds of miles on the 80- and 40-meter bands.

There are several peculiarities of this circuit which will be observed. Tuning the output network also affects the oscillator portion of the circuit, so the dip is not always as sharply defined as it would be in a plain amplifier-output stage. If the output is tuned too far below resonance, the oscillator will quit entirely and the plate current will jump to some high level. The desired dip is found at a plate-tuning setting just a little on the low-capacity side of the point where the oscillator starts. When the transmitter is fully loaded, the dip is sometimes hard to observe on the plate-current bulb and the output-current lamp will then provide a better tuning indicator.

Operating Hints

The best way to initiate a contact with this little rig is by calling CQ. Practically everyone else on the band will be using a vfo and super-selective receiver, so unless the other station just happens to be very close to your crystal frequency, the chances of making a contact by answering a CQ are poor. A good antenna will always help, and having several crystals for each band is also an asset. Last but not least, don't let the low power level discourage you. In the last ten years there has been quite an upswing in QRP activity, and many hams operate entirely with power outputs lower than that offered by this one-tuber. Remember that at the distant receiver, 10 Watts is only about an S-unit and a half weaker than 100 Watts!

I've been using the one-tube transmitter as a companion to my one-tube regenerative receiver. Like the transmitter, the receiver was built with the goal of duplicating something a 15-year-old Novice might have constructed around 1955. Together, the two pieces of gear make a nice matched station and have provided many enjoyable hours of air time.

The receiver has plug-in coils which provide plenty of bandspread on both 80 and 40, but operation has mostly been on 80 meters during the early evening hours. Forty meters at night is just too big a challenge for the receiver, although several daytime contacts have been made on that band without difficulty. Eighty is an ideal band for this type of equipment: The lack of interference, strong stable propagation, and slightly better receiver performance all contribute to long and enjoyable contacts.

The biggest practical problem is spotting the transmitter's crystal frequency with the receiver. Presumably, this wasn't as much a bother in the old days—contacts just didn't always occur on one frequency as they do now. I solved the spotting problem by cheating a little: A weak test signal is generated by plugging the crystal into a simple transistor-oscillator circuit. Perhaps some reader can suggest a more authentic spotting procedure.

Relax and Enjoy

One of the amazing things about ham radio is its great variety. Equipment can't get much cruder than the station described here: a 40-year-old circuit design using obsolete salvaged parts and hand-built with carpenter's tools. Yet this set can provide reliable communications over hundreds of miles. Most impressive of all is that more often than not when I exchange signal reports with that distant ham and his $1200 transceiver, I give him the same RST 579 he honestly gave me! (I make it a habit to get a signal report *before* I describe my equipment—that avoids the "sympathy vote.") You'll also find that nothing seems to get past the standard hello/good-bye contact habit faster than a description of this two-tube ham station. Often I can almost see the tears in the other fellow's eyes as he tells me about similar equipment built and operated in the dim past.

I'd be the last to claim that you can set the band on fire with this little transmitter, but I will promise that it's an almost zero-cost source of great entertainment. Discover (or rediscover) for yourself the flavor ham radio had in the days before passband tuning and digital readout. Build it—and enjoy it! ■

Build the Revolutionary Parastat

After some rule-bending and wire-straightening, N6LM discovered the parastat antenna. It has gain when you want and a null when you don't.

This article is directed to the experimenter, particularly one who is partial to wire antennas. No construction information, other than minor basics, is included.

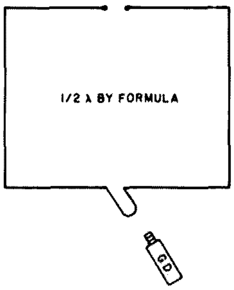

Fig. 1. Square half-wave radiator.

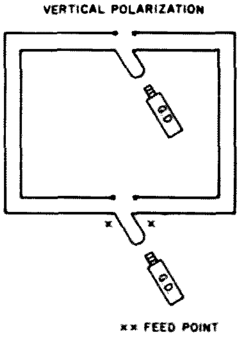

Fig. 2. Setup for vertical polarization.

The individual is permitted to fly on his own. A wall, a barn door, or Grandma's old curtain-stretchers may be used for a test stand.

To investigate the potential of an antenna for a restricted area, the old idea of the square radiator, i.e., a half-wave radiator equilateral, fed as a dipole, was resurrected. (See Fig. 1.) Years ago, this antenna was used as the basis for a spider-web array.

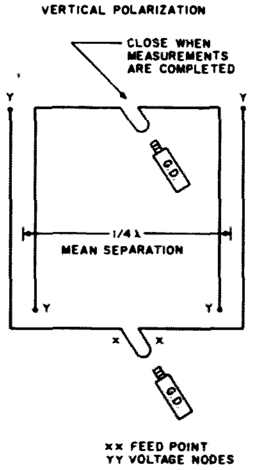

Fig. 3. Quarter-wave separation between legs.

A light X-frame was made up of 6-foot lengths of ¾-inch wooden stock, and a stand of scrap plywood

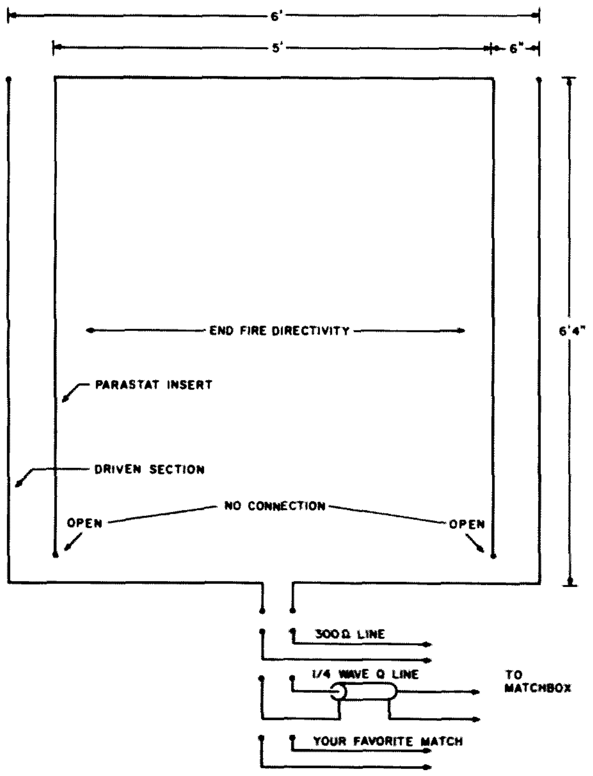

Fig. 4. Details of completed parastat antenna. Skeletal configuration guide—21.100 MHz; vertical polarization; zero broadside null. Radiation resistance is 38 Ohms, approximating that of a close-spaced radiator/director beam antenna.

was constructed to serve as our "test bed." One-inch wire finishing nails were tacked at two-inch intervals on the far ends of the X-frame to wrap, or support, our experimental antenna. No. 22 wire was used in our design. However, no. 18 bell wire or similar light copper stock would be preferable.

It is essential that a portable grid-dip meter and sensitive field-strength meter be available for pruning the antenna to desired frequency and for subsequent testing.

Getting back to our square half-wave radiator, it loaded well but its performance left much to be desired. As a receiving antenna, it was no match for a reference dipole. Rather than discard our efforts completely, we decided to play around with an unorthodox idea. Let's bend a few rules and see what happens when another element is placed inside our loop, opposite in phase, and driven electrostatically in parasitic mode (hence the name coined for this radiator: the "parastat"). See Fig. 2.

We had assumed this configuration would lower the resonant frequency, but we were not prepared for the extent of variation. At this point the grid-dip meter becomes indispensable. Start out by cutting both driven element and parasitic element to ½ wavelength of the chosen frequency, in our case 21.100 MHz. A single turn in the center of each element is set up for grid-dip-meter insertion.

Begin pruning the ends of each element for the desired frequency. Due to the proximity of the elements, an L/C relationship exists and "pulling" will occur as each is pruned to the frequency of the other. Continue pruning until the desired frequency is reached and the elements "slide" together in frequency.

Our antenna has now shrunk significantly, but it still retains some desirable features. It still loads satisfactorily; it approaches the receiving capability of the reference dipole. It also shows a marked increase in directivity and the broadside null is accentuated. Noise pick-up is greatly reduced; in fact, the antenna is now quieter than the reference dipole. On-the-air testing was favorable, signal reports were OK, and some DX was worked.

Considering further improvement, we decided to try ¼-wave separation of the two ¼-wave legs of the parastat, resulting in Fig. 3. Plan on a minimum of 20 feet of wire for each element (21.100 MHz) before pruning. Our test frame is revamped to accommodate the new structure.

A parastatic element is inserted and pruning is again undertaken to reach our selected frequency. A considerable reduction in physical dimension is again realized—to about 18% shorter than that produced by the classic formula for a ½-wave dipole. This system loaded well, showing a reasonable frequency response each side of the selected cut frequency. The system was fed with 300-Ohm ribbon line. A ¼-wave Q transformer between the antenna feedpoint and the 300-Ohm line was also tried. The ¼-wave Q line was made up of a short length of RG-58/U grid-dip cut to the operating frequency. A transmatch was used for tuning the system.

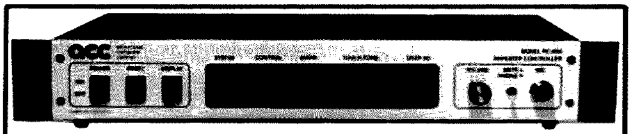
An interesting condition occurred while we were checking the directivity of the system. It was noted that the field-strength meter returned to a zero reading before the system was turned fully and completely broadside. Wondering about this somewhat strange behavior, the field-strength meter was picked up and moved to the system on a line broadside to the elements. Nothing happened to change the zero reading even when the instrument was placed directly in the center of the system. Very intriguing—a completely dead area, devoid of all radiation. Moving the field-strength meter about in this "black hole," it was found that the dead area was quite extensive, several feet in all directions from the center point of the system.

Also of interest, rather than two doughnuts or circles cheek to cheek as in a dipole radiation pattern, we found a definite elongated figure eight, indicating a reasonably sharp directional pattern.

It was a pleasant surprise to discover our latest effort surpassed the receiving capabilities of the reference dipole. It was nothing intense or remarkable, but there was a solid lift in signal strength, plus a significant decrease in noise. Signals formerly masked by background noise became readable. Local, stateside, and DX stations were worked—all continents. And the base of our test antenna stood only one foot above ground.

This configuration may be of interest to the apartment dweller or the amateur who must hide his activities in restrictive neighborhoods. It works out nicely from an interior room, having sufficient concentrated directivity to punch out a respectable signal. In areas where certain interfering signals are prevalent, its broadside black-hole null may be helpful in working around competition. It also suggests a superb HF direction-finding mode, in that the null will not spin out upon closure to a strong signal source.

For mechanical considerations and convenience, 21 MHz was used as a starting point; however, bolder amateurs may wish to project the idea to the lower frequency bands. ■



We're changing what repeaters can do . . . for YOU!

Whether you're a repeater owner, control op, or user, the RC-850 controller offers you capabilities you've only dreamed of. Like natural sounding speech synthesis . . . easy, remote Touch-Tone programming . . . talking meter readback . . . synthesized remote base operation . . . and an autopatch with features you have to hear to believe.

Most important of all, upgrade through software, prevents obsolescense. Which lets us bring you new features, like our scheduler, for automatic changeover of repeater status by time and day of week . . . And our mailbox, for leaving messages for your friends. Plus much, much more!

The RC-850 Repeater Controller—The New Standard in High Performance!

Ask anyone that owns an RC-850 controller. Or ask us for our demo tape, so you can hear for yourself.

Talk Softly and Load a Big Stick

Turn a six-foot stick into an antenna that will ramrod your signal into the ether. And when you're off the air, you've got a coat rack.

This particular antenna was born out of need for a compact aerial that could be carried easily and set up quickly, primarily for indoor use but also for outdoor application, without need to suspend the system between two points. To achieve this end I decided to use a helical-whip configuration capable of working on all bands. The whip length purposely was limited to 2 meters (a little over 6 feet—or 79").

The helix was wound on a collapsible varnished bamboo fishing pole. This choice is the least expensive and most easily available. The pole is sold as a three-piece, 3-meter length (10-foot) unit, but to allow for easy indoor use when desired, it was cut to the aforementioned 2-meter length, consisting of two sections which fasten together.

For indoor use, a wooden board 61 cm by 61 cm by 2 cm (24" by 24" by 3/4") was fitted with a vertical plate of aluminum at the board's center. The plate was drilled to accommodate two 6-32 mounting screws to hold the antenna pole at its lower portion. The mounting holes were drilled 7.62 cms (3 inches) apart. This method of construction facilitates moving the aerial around in the house (and cellar). Ease in moving it also proves useful in portable camping type of operations. See Fig. 1.

Since the plug-in portions of the pole consist of copper-plated ferrule-like fasteners, these were taped over to allow the magnet wire to be wound over the metal portion and still have a measure of good insulation. A length of #16 enameled wire 42.6 meters (140 feet) long was wound on the pole as indicated in Fig. 2. Since my antenna was intended mostly for indoor use, the pole was not weatherproofed.

The antenna has been loaded on the 80-, 40-, 20-, 15-, and 10-meter bands by means of a random-wire antenna tuner. However, especially on the 80-meter band, a very good grounding system is important. An swr ratio of less than 1.1 to 1 has been achieved on all bands.

At my location the aerial grounding system has taken the form of a water-pipe ground plus a counterpoise wire about a quarter wave long. The counterpoise was cut primarily for the 80-meter band and made to extend around the radio-room floor. Care must be taken, as the end of the wire becomes hot with rf. Because of the importance of good grounding techniques, following are some observations on developing good grounds for indoor or portable operation.

A bad ground system results in difficulty in coupling the transmitter to the antenna and creates poor harmonic suppression resulting in TVI and RFI. This is due to (1) creation of an additional impedance level because of transmitter-chassis-system-to-ground impedance, (2) loss of rf power in poor grounds as a result of radiation in the transmitter's power cord, cabinet, and ground system itself, and (3) partial loss of effect of chassis bypassing resulting in harmonic currents radiating out rather than being bypassed to ground because the chassis is not then at ground potential.

The first and easiest approach to a good system is to connect the ground at a metal cold water pipe. This should preferably be done at the point where the pipe from the local water supply enters the dwelling. Another useful ground point is the metal pipe feeding the outdoor garden hose. (Be sure that the piping is of metal and not of plastic as it sometimes is.)

A counterpoise wire (or wires) is most useful (and many times an additional necessity) as an alternative to obtaining a good ground system. That is especially true in outdoor portable use or when setting up a rig

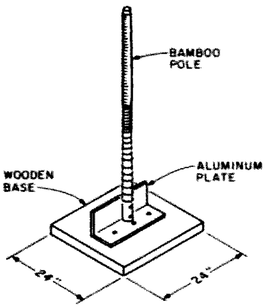

Fig. 1.

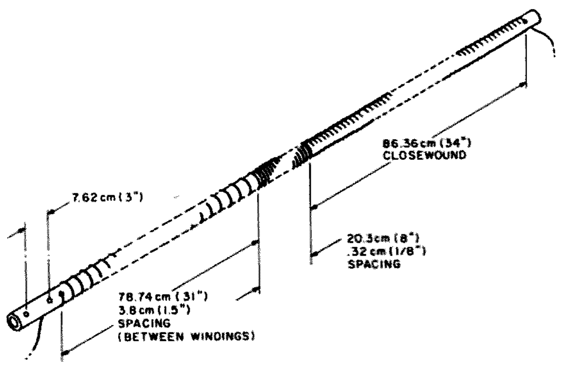

Fig. 2.

in a hotel room when traveling. The counterpoise consists of one or more wires connected to chassis ground. Each of the wires is cut to a length equal to .2 to .25 wavelength for each of various bands. The wires may have to be trimmed down a little at a time to get the most efficient ground as indicated by swr readings while the transmitter is loaded into the aerial. However, the surest way of checking out the total system is to use an antenna impedance bridge.

Either or both of the grounding methods just described plus use of an efficient random-wire antenna tuner will help load this helical antenna on all bands. With regard to the random-wire tuner, every radio amateur should have this accessory. It makes for more flexibility in antenna application, not limiting the operator to a particular type of antenna and operating band. It allows for use of almost any wire length for all amateur bands.

The antenna cost for basic materials was four dollars for the bamboo pole and two dollars and a half for surplus enameled magnet wire. The latter was easily obtained from a local transformer repair company.

As to antenna efficiency, with an output power of 20 Watts on 80- and 40-meter CW, with the aerial *in my cellar radio room*, consistent reports of 5-5-9 to 5-7-9 have been received at medium distances. This performance indicates that with placement of the antenna outdoors, it should perform as well or better than the common 30-foot base-loaded vertical. The six-foot helical antenna thus has the advantages of compactness, ease of installation, and physical durability when the aerial has been carefully weatherproofed. ■

AT LAST!

This service will be available nationally. Lab tested & time proven modifications professionally installed in your amateur Handy-Talkie 2M, 220, 440, MH2 transceiver by Henry Radios warranty technicians (KNOWN AS "A&W PRODUCTIONS")

HAVE ALL PL TONES AVAILABLE AT YOUR FINGER TIPS

Outboard the dip switch! Have it neatly inlayed into the back cover of your Handy-Talkie making all 32 PL Tones Selectable at a moment's notice.

$25 Got your own PL? Send it to us with your Handy-Talkie unit and we do the professional installation for you.

$55 We will install a new PL and inlay the dip switch into the back cover of your Handy-Talkie ready to operate.

Send us your Handy-Talkie unit and a check or money order plus $3.50 for shipping and handling payable to **A&W PRODUCTIONS, INC.**

For **TEMPO** units the dip switch is inlayed into the Push-to-Talk bar. The **TEMPO S-15** will have the dip switch inlayed into the back cover.

$45 We will install a **NEW BATTERY BEATER** in your **TEMPO S-1, S-2, S-4, S-5 READY** to operate. Your New Battery Beater will use the same jack as the charger with no new holes and regulation circuits built into unit. Comes with Cigar Lighter Adapter with internal fuse.

CONTACT A&W PRODUCTIONS FOR SPECIAL MODIFICATIONS YOU MAY WANT TO HAVE DONE. WE SPECIALIZE IN THE TEMPO HANDY-TALKIES.

WE ARE AN OFFICIAL "TEMPO" REPAIR STATION
ALL WORK GUARANTEED FOR 30 DAYS. SEND YOUR HANDY-TALKIE AND A CHECK OR MONEY ORDER TO:

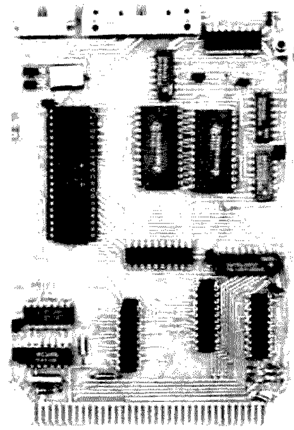
CONTROL IN BASIC

FOR $169.95



No Need For
-Assembly Language
-Development Station
-Expensive Test Gear

. . Just a Terminal

THE JARR Z8 BSC CONTROLLER

INCLUDES:
- Tiny Basic Monitor
- Timer/Event Counter
- 4K User Eprom or Ram
- Over 200 Pages of Documentation
- RS-232 Serial Line
- 14 Parallel I/O Lines
- Expandability!

FOR INTERFACING TO:
- Sensors
- Triacs
- Displays
- Relays
- Keyboards
- Switches
- SCR's
- A/D & D/A

APPLICATIONS:
- Heating Control
- Home Security
- Lighting Control
- Speech Synthesis
- Programmable Rotor Controller
- RTTY / CW Control
- Home Automation

With the Jarr Z8 Controller, 1000's of dedicated microprocessor control applications can be realized.

Development ol a control program is easy!
By utilizing simple BASIC commands, create a program to accomplish your specific task. When your program does what you want, simply download from RAM to EPROM. From, then on, whenever the Z8 controller powers up it will automatically execute your control program.

JARR Z8 Controller Peripherals:
- Eprom Programmer/Cassette Interface (Model # Z8-ECI)
- 24 Line Parallel I/O Card (Model # Z8-PIO)
- 8 Channel Relay Control Card (Model # Z8-RCC)
- 2 Channel Temperature Sensing Card (Model # Z8-TSC)
- Breadboard Interface Card (Model # Z8- BIC)
- Speech Synthesizer Card (Model # Z8-SSC)

Nick Testa K6KTS
6420 Dominica Avenue
Cypress CA 90630

Build This Cornerless Quad for 2 Meters

Here's an antenna that you can cut corners on. All you lose is high cost.

A little over a year ago my oldest son, Nick, now KA6OXP, expressed an interest in becoming a ham. After dusting off a lot of vacuum tubes, it became clear that some new equipment was in order. Among the things purchased was a pair of two-meter hand-held transceivers.

Back on two meters after many years, I wondered whether I could work some DX and contact my old friend Tom WA6FIO. Tom lives some 50 miles away across Los Angeles. Our first contact was via repeater but left a lot to be desired in a rag-chew, with timers, QRM, and breaks to contend with. After spending a modest fortune to re-equip our ham shack, the prospect was dim for obtaining a linear or even a commercial high-gain 2-meter antenna. Enter LC4ELQ!

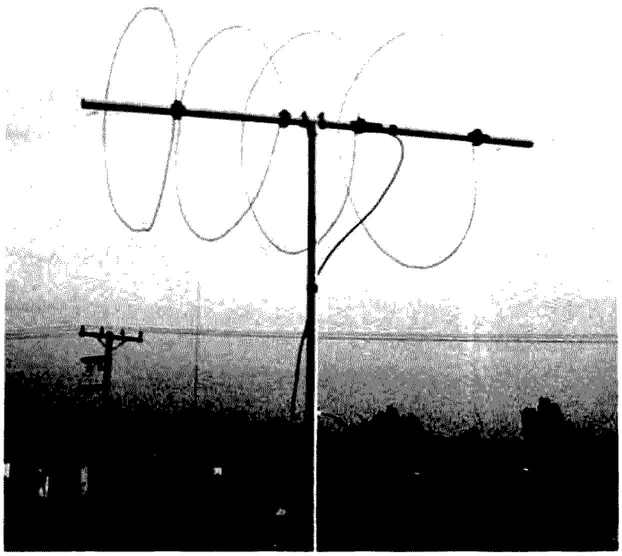
It is the answer to the question of how to boost your signal and reception on 2 meters at the lowest cost. If you have a low-power hand-held and want to use simplex across substantial local distances, as I did, or an SSB transceiver and are looking for the real DX, then LC4ELQ is for you.

It stands for Low Cost 4-Element Loop Quad. The antenna design is based on the 4-element quad but with some important changes to cut costs and simplify construction. A well-stocked junk box may contain all the necessary parts. Even if you have to buy all the parts new, except for an entire case of wire (which you will need only a small portion of), the expense will be under $10.00.

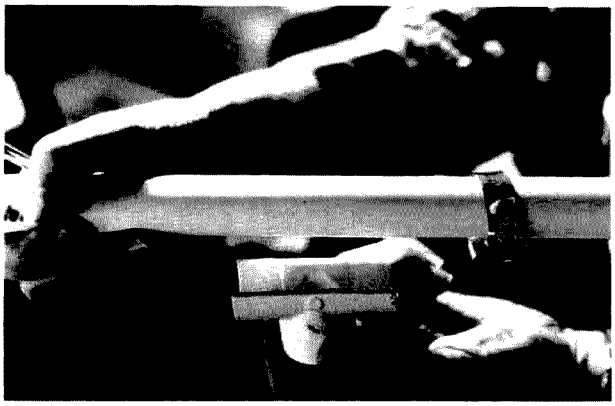
Construction

My trip to to the junk box yielded some 3/4-inch schedule 40 PVC pipe left over from a sprinkler system installation and a quantity of #8 aluminum ground wire (Radio Shack #15-036) left over from grounding my low-band rig.

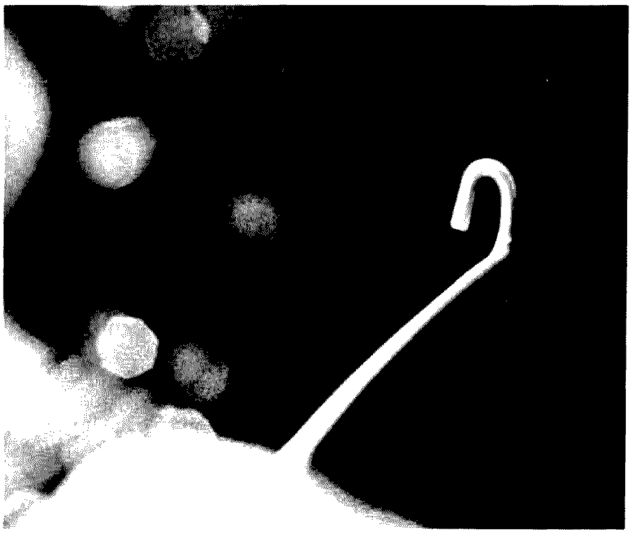
Since I was interested in the design which would have the best chance of being self-supporting, I decided to make the elements loops instead of squares. This has the added advantage of allowing adjustment



The LC4ELQ.



The cut T being positioned on boom. The hose clamp is one of two which will be used to secure the T to the boom.



Forming the bolt hook and the 90° bend.

The end of each element should look like this. Length measures in the table are from the 90° bend to the one at the opposite end. The hook is not included in the dimension.

of the element size without the constant adjustment of corners. This in fact proved very handy at the tune-up stage. Due to the stiffness of the #8 wire, adjusting corners would have made the antenna look like it had been salvaged after being hit by a truck.

Four pieces of the wire were cut to length for a driven element, a reflector, and two directors. The lengths were determined as in a 2-meter quad design such as is found in the *ARRL Antenna Book*, plus 1 inch to allow for forming hooks at the attach points, less the length of the bolts through the boom for the reflector and director elements. In those three elements the 1/4-inch by 2-inch bolts serve as 1 inch of the resonant length. Each element was then formed into a hoop with the ends bent at 90 degrees and then bent to fit around the bolt and screw heads.

The next step was to prepare the boom and mast. I cut the 10-foot piece of PVC into a 4-foot and a 6-foot length. I also cut the top bar of a PVC T joint in half lengthwise. The stem portion of the T was glued to the end of the 6-foot piece of tubing to form the mast. I mounted the 4-foot length for the boom in the U-shaped cradle formed by the remaining top of the T using a pair of 1-1/2-inch-diameter hose clamps. The hose clamps can be loosened to allow for rotation of the boom for vertical or horizontal polarization.

Three 1/4-inch holes were drilled through the boom, one for the reflector and one for each of the directors. A 5/64-inch hole was drilled through the boom for the driven element. A 1/4-inch by 2-inch hex-head bolt was passed through each of the larger holes with a pair of flat washers on each side of the boom. The small hooks at the ends of the elements were slipped between the washers at each side and a nut used to fasten the assembly.

For the driven element, a #8 by 3/4-inch sheet-metal screw was inserted in each side of the boom. Each screw has a pair of 1/4-inch washers and a #8 washer, nearest the head, mounted on it. When the driven element is mounted, the shield and center conductor of 50-Ohm coax are connected, one to each screw. The screw acts as a terminal to connect the coax to the antenna. Solder or crimp #8 spade lugs to the end of the center conductor and shield to ensure good attachment to the antenna.

To tune the antenna, I adjusted the element lengths and spacings until the antenna provided a nearly perfect match to the transceiver across the entire 2-meter band. This gave me a prototype antenna with a few extra holes in the boom. The final lengths are shown in the table of element lengths. Be sure to note that the table gives the length between the 90-degree bends and not to the tip of the wire. I recommend that you form a 90-degree bend and a small bolt hook on the end of the wire and then measure to the next bend point. Make the bend, allowing enough wire to form the

hook around the bolt or screw, and then cut the entire piece off.

In making the swr measurements, I noticed that the relative motion between the elements was enough to change the swr. To prevent this I added three pieces of fishing line tied to each element and to the ends of the boom which extend beyond the elements. If, for example, the loop is fed at the 6 o'clock point looking at the antenna straight down the boom, a length of fishing line runs along the 9, 12, and 3 o'clock positions. A knot was tied at each element with a slight inward bend of the wire at the knot point to retard slippage. The ends of the three pieces of fishing line were tied together and then passed through spare holes at each end of the boom. George N6FFA, in testing copies of the antenna, found that squareness to

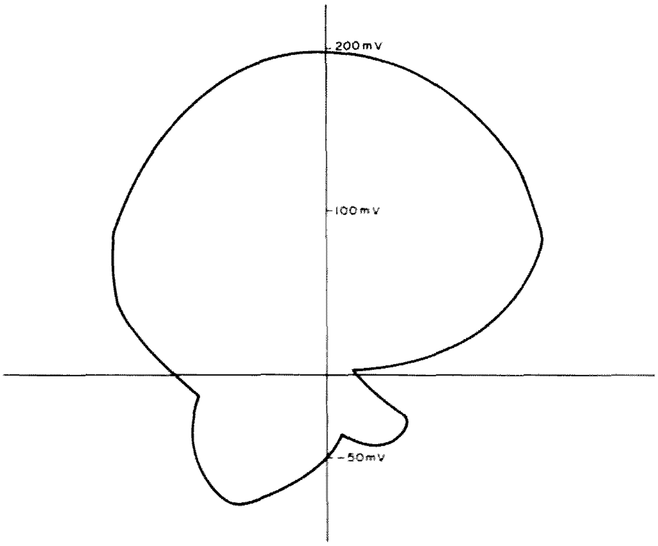

Fig. 4. Antenna pattern measured by N6FFA and KD6EH in millivolts of signal. The LC4ELQ was used as the transmitting antenna and rotated to produce the pattern.

the boom and parallelism of the elements to each other reduced the rear lobe of the antenna. That means you should do the best job you can in these areas. For long-lasting protection of your connections, wrap each with electrical tape or, better yet, use a commercial silicone sealant to cover them.

Polarization

What would you like? Since I was interested in FM, I wanted a vertically-polarized antenna. I rotated the boom so that the feedpoint was on the side, 3 o'clock or 9 o'clock looking down the boom. This gave me vertical polarization. For horizontal polarization, place the feedpoint at the top or bottom of the loop, 6 o'clock or 12 o'clock. With vertical polarization, N6FFA did notice a reversal of the deep rear side notch in the pattern, depending upon which side the feedpoint was on.

Testing

Initial tests were made with the mast held by rubber bands to the desk drawers in my shack and the boom 6 feet off the floor. Readings were taken on a Swan VHF reflected-power meter. Also checked was the performance in vertical and horizontal polarization, and rough checks of directionality were made. The antenna was then clamped above my tribander at 40 feet. Swr tests were then repeated using a Bird model 43. Both sets of test results are shown in the tables.

With the help of Judi WB6SKE, I made the first pattern check. It indicated a front-to-back ratio of 20 dB. The data is also shown in the table. The distance between our QTHs is about 4 miles. N6FFA and Greg KD6EH made the radiation pattern graph shown from the millivolts of signal measured at Greg's location about 12 miles away from N6FFA.

Performance

Yes! I was able to work WA6FIO simplex at nearly full-quieting across the Los Angeles QRM with 1.5 Watts. This same power level has easily provided reliable nearly full-quieting communications via repeaters located in other cities nearly 200 miles away. My QTH is situated on flat land at about 50 feet above sea level so our own elevation is not a factor. Several other local hams have built and used the antenna on both FM and SSB with excellent results. I constantly receive the comment on the air, "You're that far away and just using 1.5 Watts; that's some antenna!" Try one for yourself and see what I mean.

Conclusion

The LC4ELQ is hard to beat for return on your dollar investment for each Watt of effective radiated power. The ease of assembly beats anything with spreaders. One fellow says he has built several and it now takes him much less time than the 45 minutes that he spent on the first.

If you're interested in minimizing your time in construction, drop me an SASE asking for information on a pre-cut and -drilled kit version. ■

Tuned Feeders for Oddballs

To get that good DX you've been missing, add some versatility and multi-band capability to your wire antennas.

The use of tuned feeders makes possible the construction of a single antenna that will work well on two or more bands and which will load up equally well on any frequency in each band, whether the frequency is phone or CW.[1] Tuned feeders will feed "oddball" antenna-wire lengths that would be impossible to feed with coaxial cable.[2] Tuned feeders also have other advantages that have been described in previous *73* articles.[1,2,3] Because of these things, radio amateurs who like to experiment can use tuned feeders to try out many different antenna ideas. The one disadvantage of tuned feeders (resonant lines) is the extra work of adjusting the antenna tuner. However, people who like to experiment usually do not mind this extra work.

Vertical polarization is not commonly used with beam antennas even though it has worthwhile advantages for DX communication. The purpose of this article is to present some experiences and ideas which will encourage its readers to experiment with vertically-polarized beam antenna systems fed with tuned feeders.

It is axiomatic that at easily attained heights, vertical antennas radiate rf at lower angles to the horizon than do horizontal antennas.[1] This accounts for those cases in which vertical antennas have made DX contacts that horizontal beams have been unable to make.

For many years I worked DX using vertical antennas, but was unable to work DX using horizontal antennas. It was only natural for me to think in terms of vertical polarization when I decided to build a beam antenna. The first result of this thinking was what was called the "Chinese Inverted Ice Tongs Antenna," so named because it was made of two long bamboo fishpoles and had such a shape. See Fig. 1. This was a two-element vertical beam for 20 meters using an antenna wire and a reflector wire supported by a frame made of the bamboo fishpoles and some 1-by-2-inch lumber. The antenna was fed as a vertical J. This antenna worked DX quite well. (The bottom of the antenna was 40 feet up from

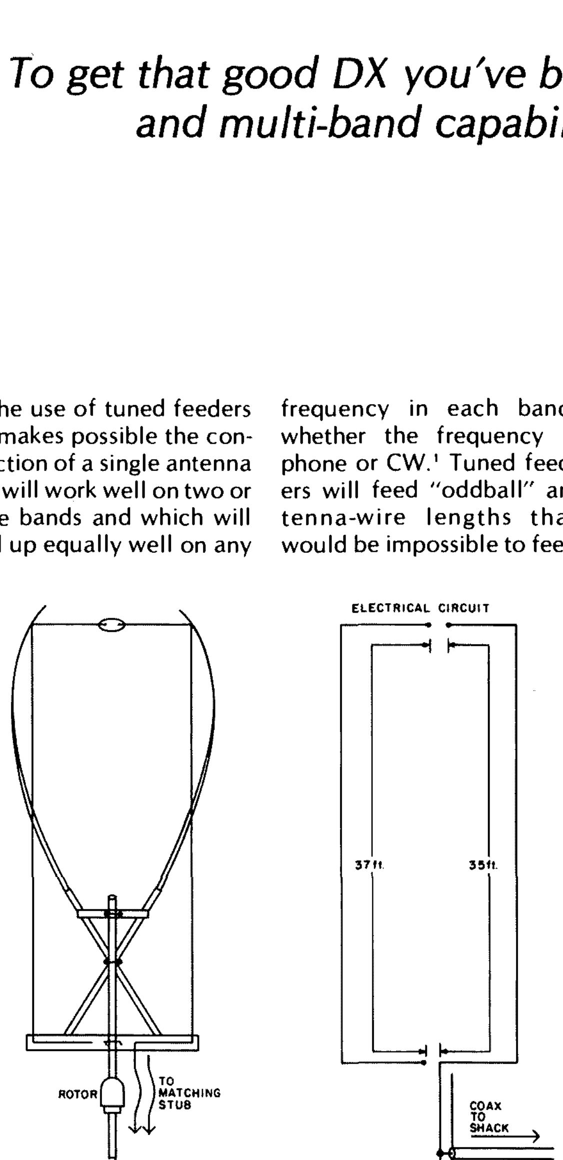

Fig. 1. "Chinese Inverted Ice Tongs" vertical beam antenna. Tuned feeders could have been used.

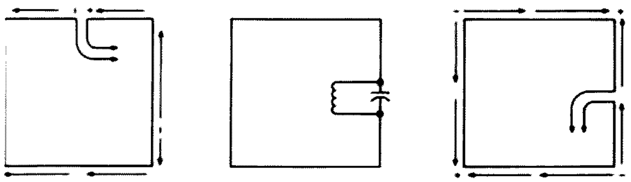

ig. 2. 20-meter quad tuned to resonance on 15 meters (left) ind 10 meters (right). Reflector with 15-meter trap in vertical vire behind the feedpoint is shown in center.

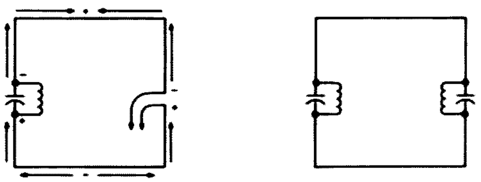

Fig. 3. Use of 10-meter traps to make a 20-meter quad fed with tuned feeders function as an "expanded quad" on 10 meters. (Reflector traps are tuned to a frequency just outside the low-frequency end of the band.) On the left is a 20-meter quad antenna tuned to 10 meters with a 10-meter trap opposite the feedpoint. On the right is a 20-meter quad reflector with 10-meter traps in the vertical wires.

he ground. "There is no substitute for height," as Harry, ıy best radio amateur friend nd "consulting engineer," ften remarked. When I told larry about the DX QSOs, e laughed and replied, Well, the laws of physics ave not been repealed.")

The next vertically-polar-ːed beam was a 2-element 0-meter quad fed in the enter of one of its vertical /ires. This antenna also /orked very well. When I ıoved to another state, I ut up the quad and fed it in ıe center of one of its verti-al wires using tuned feed-rs for vertical polarization. he antenna worked even etter than it did before, ven though it was about 6 eet lower than it was in its ormer location.

One of the characteristics ıf a vertically-polarized ıeam is that the rf is radi-ted in a wide-angle beam. his has been very helpful in arrying on three-way sched-ıles from St. Louis with tations as far apart as cottsdale, Arizona, and ake Stevens, Washington. I ıoint the quad at whichever tation is weaker and both tations can copy my sig-ıals. The great width of the ıeam is especially helpful vhen I do not know the ex-ıct direction in which the ıeam should be pointed. Some people might consid-ːr this wide beam to be a lisadvantage, but I have not ound it to be so.)

The 20-meter vertically-ıolarized quad is excel-ent for working DX. When he band is usable, the DX tations that are called ısually answer. The tuned feeders put the rf into the antenna with great effectiveness. If there had been any doubts about this, they would have disappeared when I worked YU5FAM with less than 1.25 Watts rf output from a Heathkit HW-8 QRP transceiver.

As an experiment, the 20-meter quad was tuned up on 15 meters. It worked very well on this band and many DX stations were worked. A mental analysis of the standing waves on the antenna shows that the two vertical wires of the antenna are excited in phase (broadside radiation). The rf standing waves on the horizontal wires cancel each other. It is hard to know what is happening in the reflector. It may be acting only as a shield to make the beam unidirectional. A 15-meter trap in the reflector on the same side as the feedline would probably make the reflector into a real reflector on 15 meters.

A mental analysis of the standing waves on the 20-meter quad loop, if tuned to 10 meters, showed that the vertical wires would be 180 degrees out of phase and would provide endfire gain and directivity in the plane of the two wires. See Fig. 2. This would be at right angles to the way the quad was pointed as shown on the rotor control box. The vertical endfire beam would be bidirectional. (The horizontal wires would be 180 degrees out of phase also, but the up and down endfire effect would not be useful for terrestrial communication.) The quad was tuned up on 10 meters and the plane of

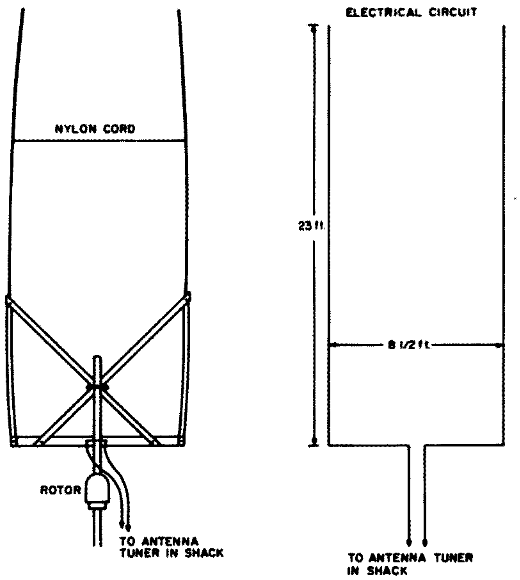

Fig. 4. The "XU" bidirectional beam antenna.

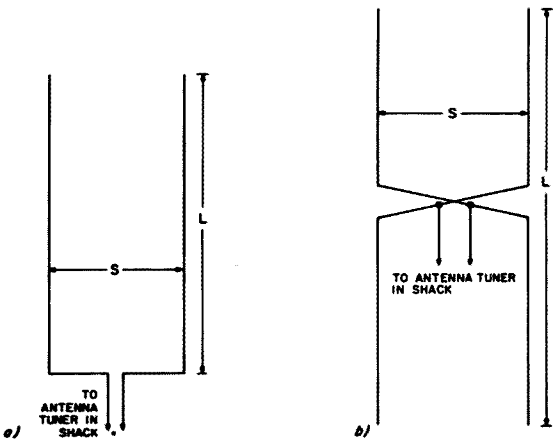

Fig. 5. Electrical circuits of fixed vertical endfire beam antennas. (a) Bottom endfed W8JK endfire vertical beam antenna. (b) Centerfed W8JK endfire vertical beam antenna.

the wires was aimed towards Europe (45 degrees plus 90 degrees, or 135 degrees clockwise from north on the rotor box dial). The first European CQ answered did not result in a QSO, so I called "CQ DX." G3ZRH replied,

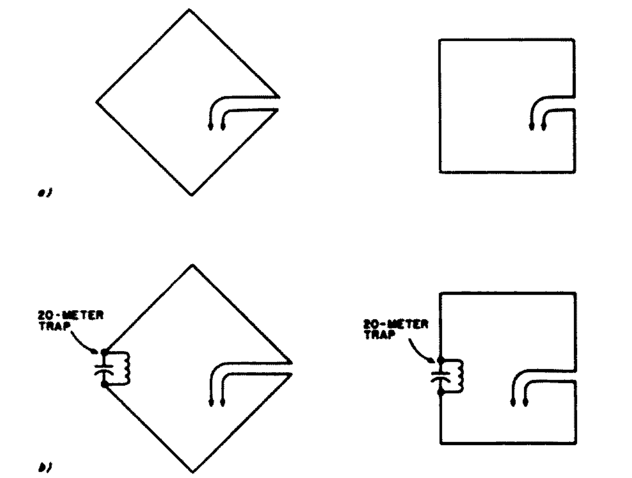

Fig. 6. (a) Vertically-polarized 40-meter quad loops (34 feet each side with tuned feeders going into shack). (b) Vertically-polarized 40-meter quad loops with 20-meter traps for "bisquare" functioning on 20 meters.

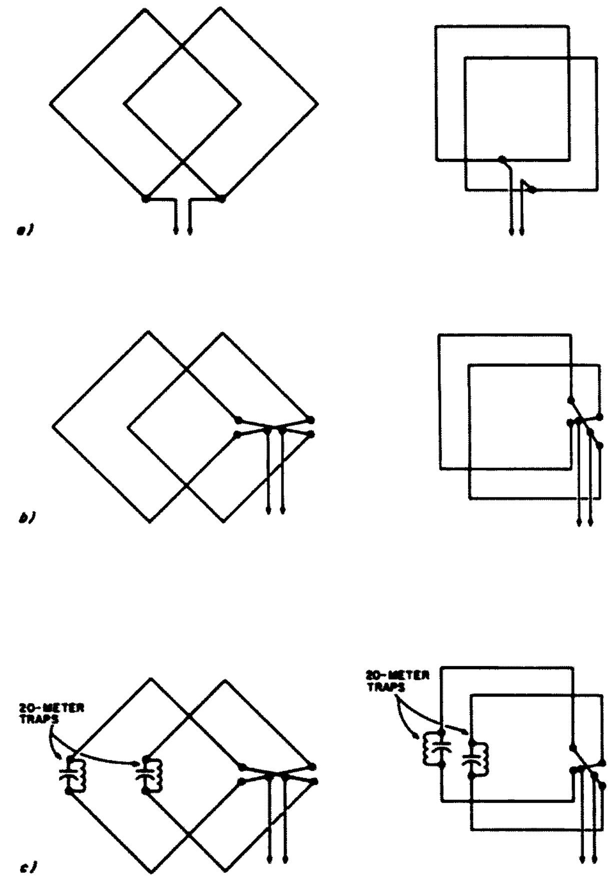

Fig. 7. Two-element vertically-polarized bidirectiona 40-meter quads—bottomfed (a) and sidefed (b). (c) Sidefe vertically-polarized two-element bidirectional 40-mete quads with 20-meter traps for "bisquare" functioning on 2(meters. (Each side of these antennas is 34 feet long. Dis tance between loops is 17 feet.)

giving a 549 report. DJ4DA, DJ4IR, and OK1KPA were worked by calling "QRZ?" at the end of contacts. Another contact was made by answering the CQ of EA4VQ. "QRZ?" after that QSO brought back SM7DWY. The worst signal report from these six consecutive QSOs was the first 549. At least the 20-meter quad could be used on 10 meters.

According to the graph of Fig. 4-20 on page 140 of the ARRL *Antenna Book* (13th Ed.), the gain of half-wave elements fed 180 degrees out of phase and spaced ½ wavelength is slightly more than 2 decibels. The vertical polarization and the one-wavelength height above ground probably account for the good results on ten meters described above. However, a gain in the normal direction of 7 or 8 dB could be obtained on ten meters with a 20-meter tuned-feeder-fed quad by using ten-meter traps as "insulators" in both the antenna and reflector. See Fig. 3. This would make the antenna an "expanded quad" on ten meters.[3]

Endfire beam antennas can be used on two or more bands when they are fed with tuned feeders. The endfed W8JK antenna can be mounted vertically and fed on the bottom with tuned feeders. The spacing between the elements should be ⅛ wavelength for the lowest frequency to be used. The length of the vertical elements should be no longer than ¾ wavelength for the highest frequency to be used. Twenty-three-foot vertical elements spaced 8½ feet apart make a good setup for an endfire bidirectional beam for 20, 15, and 10 meters. Vertical elements 26 feet long would be better electrically, but would be more difficult to build. Twenty-three feet can be obtained by telescoping two 12-foot lengths of aluminum alloy tubing with an overlap of one foot. (This tubing is sold in 12-foot lengths; outside-diameter sizes differ by ⅛ inch and .035-inch-thick walls permit the tubes to telescope into each other.) Twenty-three-foot bamboo fishing poles make very good vertical antenna supports. My endfire beam used two 23-foot bamboo poles, each with 23 feet of number 12 insulated house-wiring wire taped to it with electrician's tape. The bamboo poles were held in place by an X-shaped frame constructed with 1" × 2" lumber. Because of its appearance and the bamboo poles, it was named the "Chinese XU Antenna." See Fig. 4.

In constructing the XU, the bamboo poles were pointed a bit outward. About six feet down from the tops of the poles, a nylon cord was fastened to pull the poles together. This tension preserved the 8½-foot spacing between the wires.

Since 23 feet is only ⅓ wavelength on 20 meters, the beam was somewhat less effective on that band than it was on 15 and 10 meters. However, it did work fairly well on 20 meters. In a 20-meter QSO with a station in Leningrad (USSR), the signal report given was 579. When the transmitter was switched to the 20-meter quad, the signal report wa: changed to 599. That th center of the quad wa: somewhat higher than tha of the XU may have been factor in the better report Until a heavy storm took i down, the XU performe very well on 10 and 15 meters. The rotor used was ar old CD-AR-22. If one canno afford a quad or yag (mounted up 70 feet), an X bidirectional beam woul be well worth considerin Besides being less expensiv than a quad, an XU is easie to put up.

Two fixed vertical anten nas can be fed 180 degree out of phase to form a bidi rectional beam. For a bid rectional beam to be use on 80, 40, and 20 meters, th spacing (S) between the ve

tical elements should be 35 feet (1/8 wavelength for 80 meters). For a bottom end-fed antenna, the height of each element (L) should be no more than 50 feet (3/4 wavelength for 20 meters). See Fig. 5(a). For a centerfed vertical W8JK beam, the total height of each element could be as long as 100 feet if one could find mechanical means of supporting such heights. See Fig. 5(b).

Although the beamwidth of such a beam would be very broad, the tuning of the antenna tuner would be sharp (especially on 80 meters) and the tuner would have to be carefully touched up when changing frequencies within a frequency band (because of the relatively high Q of the antenna system).

A full-wavelength vertically-polarized quad loop would be good for working 40-meter DX. For vertical polarization, the quad loop should be fed on one end for the diamond-shaped loop, or on one of the vertical sides of a square loop. See Fig. 6(a). This loop would have a gain of 1.4 dB as compared with a dipole and would have low angle radiation.

By putting a 20-meter trap in the loop opposite the tuned feedline, the antenna would become a "bisquare array" on 20 meters with a gain of at least 4 dB as compared with a dipole.[3] See Fig. 6(b).

Using tuned feeders, a fixed quad with two loops can be made bidirectional. See Fig. 7. Two 40-meter loops 34 feet on a side with 34-foot spacing between the loops, as shown in Fig. 7(a), would provide a gain of 3.7 dB on 40 meters as compared with a dipole. This antenna system would also work on 80 meters and would be vertically polarized on both 40 and 80 meters. If 80-meter operation were not desired, the spacing between loops could be reduced to 17 feet and provide a gain of 4.3 dB as compared with a dipole.

Feeding the loops on the side with the conventional W8JK center-feed method would also provide vertical polarization. See Fig. 7(b). A 40-meter bidirectional quad could be made to function as a bidirectional expanded quad on 20 meters by adding a 20-meter trap in the center of each side, opposite where the feedline is connected. On 20 meters, the gain would be at least 7 dB as compared with a dipole. See Fig. 7(c).

If you have never tried a vertically-polarized beam or if you cannot afford a commercially-made quad or yagi "way up in the air," try one of the vertically-polarized beam antenna systems described in this article. With a good, carefully adjusted antenna tuner, each of these antenna systems will load up equally well on both phone and CW frequencies in each band, with a very low swr on the coax between the transmitter and the antenna tuner (usually 1 to 1). This will make the transmitter happy, and the resulting DX QSOs will make you happy. For good DXing, try a vertically-polarized beam antenna. ■

SATELLITE TELEVISION RECEIVER KITS

Rainbow makes a top-of-the-line

The Electronic Rainbow Receiver consists of a receiver with an external down-converter that mounts at the antenna, feeds the voltage to the LNA through the coax cable. The 4GHz signal is down converted to 70 MHz and is fed through the RG59/U coax to the receiver.

Rainbow Kits are supplied with simple step by step instructions. All the circuits that you need expensive test equipment to do are pre wired and tested. All printed circuit boards have the outline of each part printed on them.

RECEIVER FEATURES
Built in RF modulator • Detent Tuning-3.7 to 4.2 GHz • Variable Audio-5.5 to 7.5 MHz • Invert Video • Channel Scan • Voltage monitoring • Meter output • Remote Tuning
SPECIFICATIONS:
Single Conversion Image Rejection Downconverter • Threshold 8 db CNR • IF Bandwidth 24MHz • Output IV Audio and Video • IF Frequency 70MHz • Video Bandwidth 4.5MHz • Size 3½"Hx8½"Dx11¼"W

Complete Satellite TV Receiver
KIT #1 — Contains:
• Mainboard • Tuning Board • Downconverter Board • Modulator Board
• All parts needed to complete receiver
• Down Converter built in case.
• Cabinet, attractive black brushed anodized metal with silk screened front and back for a professional look
• 70 MH2 Filter is pre-wired and tested.
• Complete instruction Manual. **$395.00**

KIT #2 — **Board Kit** Contains:
• Main Board • Tuning Board • Downconverter board • Modulator Board
• Parts List, assembly and alignment manual
• 4GHz local oscillator and 70MHz filter is pre-wired and tested. **$129.00**

Instruction manual. Contains printed circuit board layouts, parts placement, and alignment instructions. **$25.00**

Condo Secret Agent

The word at many condominiums is "no antennas allowed." Here's how one ham survived.

Have you ever seen a notice like this: "... *no exterior antennas and aerials shall be erected except as provided under uniform regulations promulgated by the [condominium] Association*"?

This standard phrase or similar wording used by most Florida condominiums dismays amateur operators contemplating purchase of a condominium housing unit. When one buys into the condo, one agrees to abide by the Declaration and the Association bylaws. There is a considerable body of law under Chapter 718 in the Florida Statutes called "The Condominium Act." The law specifies a Declaration of Condominium as a kind of Magna Carta designed to protect both the developers and owners in organizing and operating a condominium community. The Declaration is a legal instrument recorded in the public records of the county where the condo is situated.

The Association is a nonprofit corporation made up of the unit owners of the condo. Members elect a Board of Administration which runs the affairs of the condominium. It has legal recourse in the event of Declaration or Association bylaw violations. Most condominiums (particularly those with lawyers on the board) are hard-nosed about sticking to the letter of the Declaration. So, how does the ham cope with these restrictions?

The condo purchaser can treat as his own private home the space contained *within the interior walls of his unit*. He can install an inside antenna, if he wishes, subject to other restrictions prohibiting nuisances (TVI, RFI, etc.). The exterior walls, roof, parking lots, trees, lawns, recreational areas, etc., are considered Common Elements to be used and enjoyed by all owners collectively.

Then there are Limited Common Elements *outside the exterior walls*, such as patios, balconies, and garage stalls which may be used exclusively by the owner whose unit adjoins or is attached or assigned to such Elements. This *might* be an out for hams who mount mobile antennas on balcony railings—maybe.

Many condo hams surreptitiously use the "invisible" antenna, an end-fed random length of fine wire strung across a lawn or roof. Some load up down-spouts or metal gravel-stops around the roof—TVI generators if the joints are not welded or effectively bonded. I have heard of ingenious hams who magnanimously donate flagpoles to their condominiums which actually are PVC masts concealing trap verticals inside, with Old Glory proudly waving in the rf field. Other amateurs temporarily run coax out windows and feed mobile antennas on their nearby autos—apparently legal, but creating safety hazards if the cables can be tripped over.

And some hams brazenly install antennas on their condo buildings without permission, hoping they can get away with it. Perhaps some do. Others, such as the writer, attempt to get permission from the Association.

Shortly after moving into my condo, I asked the board president for permission to mount a couple of simple antennas. (Forget about beams and phased arrays—don't press your luck!) I told him I wanted an inconspicuous dipole raised within a line of palm trees along the beach dune, about 100 feet from the building, and a small vertical rod for two meters on the roof. The president cited the Declaration restriction, but said he would allow me to bring up my request at the next annual membership meeting. So, my plea was included under New Business on the agenda.

At the meeting, my

resentation emphasized 1e public service aspects f amateur radio, such as roviding emergency com- ıunications during power r telephone outages fol- ɔwing storms or hur- canes. That perks up in- ɜrest among Florida East oast residents. I also ssured the membership ıere would be no towering tructures or rotatable lements (unsightly in the yes of non-hams). There 'ould be no loose cables or ɜngles of wires, I promised. .nd I also could promise no VI since our building was ɜrved by cable TV. (So far, o problems have been ɜported.)

After a few questions, all f them friendly, the mem- ership voted to grant my ɜquest, and the action was ɔ recorded in the official ıinutes of the meeting. A ɜgal-eagle type might uestion whether the As- ɔciation could waive a rovision in the Declaration 'ithout properly amending . Whatever, I at least ob- ɜined from the Association n agreement not to en- ɔrce the pertinent provi- ion. And I was in business.

It seemed prudent, even 'ith permission, to ıinimize use of the Com- ıon Elements, using imited Common Elements designated for my personal se) and my own private roperty where possible. he exception was the ipole which had to be ıounted among Common lement trees and the eedline under the Com- ıon Element lawn. RG-8/U 'as buried in a lawn slit 'hich quickly grew over nd is undetectable. The oax emerges beneath a ıalm tree and is neatly lressed up the trunk where he antenna center feed- ɔint is secured. The dipole ; a 75-40 meter trap affair 'hich also loads up fairly 'ell on 20 meters. The two- neter Ringo Ranger was nounted on the roof air-conditioning unit which is my private property. Its maintenance and ultimate replacement are at my expense, not the Association's.

Then came the sticky part—how to get the feedlines out of the apartment without drilling holes through the exterior Common Element walls. Access to the dipole resolved itself. I discovered a one-inch plastic pipe had been installed under the apartment floor to drain the air-conditioner condenser in the utility room. The pipe terminated at ground level outside. Obviously, this was a Limited Common Element for my use, so it became a conduit for a length of RG-58/U, connecting outside to the heavier coax to the dipole.

Next, how to get the coax to the Ringo on the roof? Certainly, cable snaked up the exterior wall and across the roof would be a no-no. What about the space between the interior walls, as in concrete block? This seems to be a gray area, although it probably is a Common Element. No matter. Through that space runs thin-wall metal conduit from the utility room to the roof. It contains the ac wiring for my roof air-conditioning unit. Again, this seems to be a Limited Common Element for my use, so with an electrician's fish-tape, I pulled up another length of RG-58/U to the roof circuit-breaker box (my private property) adjacent to the air-conditioner where the vertical was installed. (Eventually, I replaced the RG-58/U with Radio Shack's new small-diameter RG-8/M.)

Later, I replaced the Ringo with a Cushcraft ATV-3 20-15-10-meter trap vertical. (Well, 14 feet is still a "small vertical rod," isn't it?) I could work the local two-meter repeaters with an inside antenna. Radials for the new vertical were out, of course, since this would require a multiwire radial system extending over and secured to the Common Element roof. Ground-strapping the antenna base with heavy braid to the metal mass of the air-conditioner housing seems to work about as well as radials, with only small excursions from the manufacturer's impedance and element-length specs.

Incidentally, an unexpected bonus came with the three-band vertical: It turned out to be four-band! It seemed to load up, get out, and receive as well on two meters as the Ringo. A check with the swr meter at the transmitter indicated almost 1:1 in the 146-147 MHz range. I can't explain it!

The apartment dweller often has problems running coax from one room to another. My cables enter the apartment in the utility room which is separated from the ham shack by a bathroom. At first, I could find no easy and inconspicuous way to route the cables across the Porcelain Palace. Then I noted the one obvious fixture which spanned the walls—the shower curtain rod! A little masonry drill work on *my* walls, and the shower rod became a conduit for the coax.

I have been operating from my condo for three years, and so far there has been no complaint from any of the owners. Although I have a 1-kW linear, I use it sparingly. The exciter output level is adequate in most situations. But even with the linear, I have had no indications of interference.

Maintaining a low profile is one way to retain the operating privilege after obtaining it. Hence, the semiconcealment of my QTH. ■

Make the Icom 720A Work for You

This rig knows when you change bands, so why not let it switch your antennas? Build this simple add-on and let your voltage do the work.

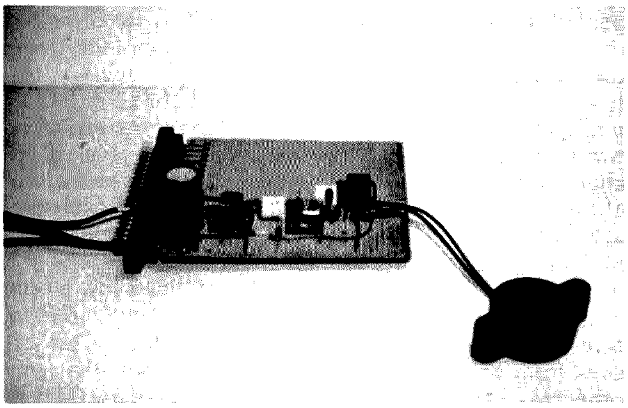
Having recently acquired an Icom 720A and played with it for several weeks, I decided to investigate some interface controls utilizing the information interface provided on the back panel (24-pin molex® plug). According to the operator's manual, pin 13 provides an output voltage which varies with respect to the band selected. The voltage, as indicated by the manual and my test, changes approximately 1 volt per band—following this pattern: 1.8 MHz ≈7.0 V, 3.5 MHz ≈ 6.0 V, 7.0 MHz ≈ 5 V, 14.0 MHz ≈ 4.0 V, 18-21 MHz ≈ 3.0 V, 24-28 MHz ≈ 2.0 V, 10 MHz ≈ 1.0 V.

Now, being basically lazy (and forgetting to change the antenna from the beam to the inverted vee), I decided to design an interface which would do it for me. I needed a circuit which would define and capture a voltage threshold and switch my antenna (via a coaxial relay) when my rig makes the transition from a low band to a high band.

Since 4.5 volts and lower represents the high bands and 5.0 volts and higher represents the low bands, what I needed was a switch that was off (0 V) for an input voltage greater than 4.8 volts and on (Vcc) when the input voltage was less than 4.8 volts. The 4.8 volts is the threshold voltage I selected. My source voltage (Vcc) is 13.8 volts. (By the way, the 720A provides 13.8 volts out on pin 2 with pin 8 being ground.)

I needed an op amp which was easy to use with a single-ended power supply and had a fairly decent slew rate. It was a job for an LM3900, set up as an inverting comparator. Next I needed an NPN transistor capable of switching relay-coil current; I chose the good ol' 2N2222. Since my relay has a coil-voltage rating of 5 volts and my source voltage is 13.8 V, I needed to drop about 8 volts. The transistor will drop about 1 to 1½ volts when saturated (on). Use an LED to drop another volt or so. The LED also lets you know when the comparator has switched states and that the transistor is on. A 100-Ohm resistor completes this series circuit.

The schematic in Fig. 2 shows a few things I haven't talked about, such as a diode across the relay coil, a couple of capacitors, and a spe-



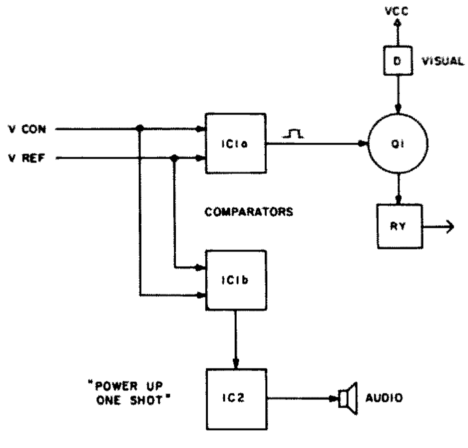


Fig. 1.

cial audio circuit (more on this later). Let's get to the heavy stuff—making the comparator switch states. The output of the comparator will be in one of two states: 0 volts and Vcc (approximately). If you prefer to think in logic, 0=0 volts and 1=Vcc. The output of my Icom 720A (pin 8) was 5 volts on 7.0 MHz and 4 volts on 14.0 MHz. A note here—If you refer to the pattern of changes given in the first paragraph of this article, you will see that it is arranged in order of the output voltage, not the amateur bands. Therefore, when you change from 14 to 7.0 MHz, you go through 10 MHz. In terms of voltage you will go from 4.0 volts (14 MHz) through 0 volts (10 MHz) back to 5.0 volts (7.0 MHz) and the relay will drop in and out. This is the reason I have a 470-uF capacitor (C1) on the input of V control to help hold this voltage up.

I selected 4.8 volts as my threshold voltage (Vref). When the input goes above 4.8 volts, the output goes low (0 volts), and when the input goes below 4.8 volts, the output goes to Vcc. The output I'm referring to is that of the comparator—pin 4, with pin 2 being Vref and pin 3 being Vin. To get Vref, a simple voltage divider will do. Referring to Fig. 2, we see that R2 is 10k Ohms. What we need to do now is to determine the value of R4. Using the voltage-divider rule:

$$\mathrm{Vref} = \frac{\mathrm{R4\,(Vcc)}}{\mathrm{R2} + \mathrm{R4}}$$

$$4.8\ \mathrm{V} = \frac{\mathrm{R4\,(13.8\ V)}}{10\mathrm{k} + \mathrm{R4}}$$

$$48\mathrm{k} + 4.8(\mathrm{R4}) = 13.8(\mathrm{R4})$$

$$48\mathrm{k} = 9(\mathrm{R4})$$

$$\mathrm{R4} = \frac{48\mathrm{k}}{9}$$

$$\mathrm{R4} = 5.33\mathrm{k\ Ohms}$$

If someone uses other than 13.8 V as Vcc, then Vref will change. To eliminate this problem, use a 25k-Ohm trimpot.

Special Audio Circuit

The 720A is a very good rig for the sightless amateur by virtue of the fact that it establishes certain operating parameters and conditions when powered up. With this being the case, why not make the modifications useful for the sightless amateur? Since the LM3900 is a quad-op-amp package and I'm only using one of the four op amps, it would be a simple task to generate another control line whose output voltage would follow that of the first op amp. I call this op amp 1B. When I say simple, I mean it—just parallel the inputs—pin 12 to pin 2 and pin 11 to pin 3. By doing this, both op amps have the same input resistors (R1 and R2) and both use the same Vcon and Vref voltages. The output voltages—pins 4 and 10—are identical, yet independent of each other.

Op amp 1B is used to turn on a 555 which is wired as as "power up one-shot." When this circuit is activated, a high (Vcc) appears on pin 10 and a short beep will be heard from the solid-state piezoelectric speaker. The time duration of the beep is set by R8 and C2. This beep will occur at the same time the LED comes on, indicating that the antennas have been switched.

The project can be built in one evening with Radio Shack supplying all the parts except the coaxial relay for approximately $20.00. Layout is not critical and point-to-point wiring can be used. (I used a prototyping board to test the circuit and then transferred to an edge-connector board.)■

The New Communications: VHF Mailboxes

Join the growing wave of hams using digital techniques to get their message across. AF2M describes the (log) ins and outs of mailbox systems.

Robert Swirsky AF2M
412 Arbuckle Avenue
Cedarhurst NY 11516

Radioteletype is a mode that is getting much attention these days. With so many hams using microcomputers and the large number of people with Teletype™ model 15s, 19s, and 28s, the popular RTTY frequencies are crowded.

One of the reasons RTTY is so popular is that the mode is especially suited to automated and computerized embellishments. It is possible to leave the TTY machine set up, leave the shack, and return to see whatever activity was on frequency. To facilitate this, the autostart system was developed. Autostart senses a mark signal on frequency and readies the Teletype machine for copy. This way, the TTY is not on all the time and doesn't print out garbage in the absence of a signal.

While autostart is all well and fine, it does have some serious limitations. One of them is that you receive a copy of everything sent on frequency. If you are just looking for one specific message, you might have to do some digging in order to find it. Also, there is no way of knowing if a message that was sent was ever received. After all, the other station could shut his receiver off before you came on frequency to send him a message.

Because of these limitations, hams started using WRU and Selcal. WRU is a special non-printing control character that causes a properly equipped RTTY machine to send out an identifying message every time the character is received. In order to use WRU legally, there has to be a licensed control operator at the station; this limits its usefulness a great deal. Selcal is a selective calling system. It activates the TTY machine when a specific sequence of letters, usually the last three letters of the station's callsign, is sent. The TTY will remain active until another series of characters, usually NNNN, is received. Selcal is a very useful item, but it is prone to false start-ups and not too many hams have the proper equipment to use it.

A few years ago, when microcomputers were first getting very popular, RTTY mailboxes started popping up across the country. These systems enable a ham on RTTY to leave a message in a computer's memory. The message is then received when the station to whom the message was directed checks into the system. In order to use a mailbox, no special equipment is necessary. Anyone who can get on 60 wpm Baudot (45.45 baud) can use most of the systems that are around.

The procedures for using the various RTTY mailboxes vary from system to system; the one I will describe is that of the Uncle Floyd Radio Club, WA2DCS, which is based in Queens, New York. The operation of this system is roughly the same as the other ones I have tried.

NO MORE MESSAGES.
```

Fig. 2. An illustration of how messages may be inspected and, if garbage, deleted to conserve disk space. This feature is available only on the local terminal, not over the air.

The following is an example of how a message is left:

WA2PAK.
THE HW-30 SOUNDS FB ON THE AIR. I WAS ABLE TO GET AHOLD OF A SIXER. WANNA BORROW THAT TOO??

After the last message is sent, the station types:

LOGOFF

The system responds with a:

GOODBYE, KB2UF.
(CW ID)

This system is rather typical of most of the 2-meter mailbox systems that I have seen. There are some on the low bands; operation on them differs slightly. The 2-meter band is an ideal one for this type of operation because one does not have to worry about QRM, QRN, drifting, selective fading, and other things that plague the lower frequencies.

In order to set up a mailbox system, all that is needed is a computer with a fair amount of disk space, a medium-power 2-meter rig, a stable TU that produces a nice clean AFSK tone, and a good omnidirectional antenna at a decent height. Since every setup will differ, the software would have to be custom-written for the specific equipment involved and the needs of the club.

When writing software for such a project, it is often a good idea to start with a commercially-available program and modify it to suit your needs. This way, much time will be saved. The mailbox system described in this article uses an Apple II Plus computer. The Baudot, ASCII, and CW routines were taken from a program that had assembly language subroutines written for the various codes and an Applesoft BASIC program controlling the display, flow of control, and other such things.

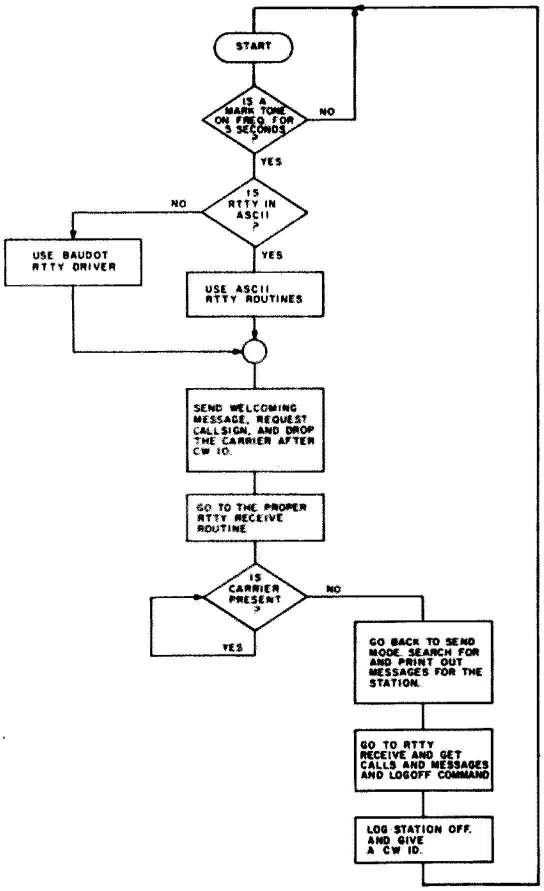

Fig. 3. Flowchart for a basic mailbox system. The RTTY send routine takes care of the CW ID. Random-access disk files are used. This limits length but greatly speeds research time.

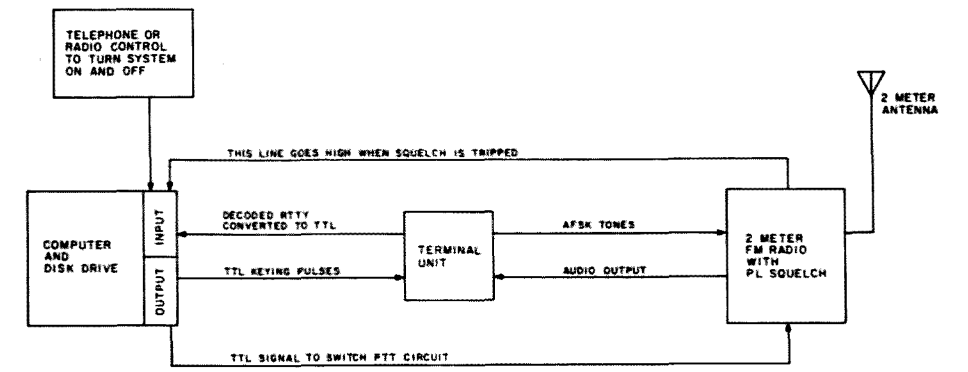

Fig. 4. The various components in the system and their interconnections. The 2-meter rig was modified to provide an external audio output, external PTT input, and a TTL-level output line to tell the computer when the squelch is tripped.

The Applesoft executive program was modified in such a way as to enable the program to function as a mailbox. The task was not as difficult as it sounds; it took one person less than a week to perfect the program. As portions of the program are from a copyrighted program, I obviously am not able to supply a listing of the modified software. If you feel that you are not capable of writing the software, companies such as Macrotronics advertise mailbox software for the TRS-80 and other popular computers. Also, Hal makes a complete stand-alone system, with a dedicated microprocessor terminal for ASCII and Baudot.

If you decide to write your own software, it is wise to plan carefully ahead of time. Get together with other RTTY operators and decide what features you want to include and how to go about implementing them. Draw one flowchart picturing flow of control throughout the entire system and one showing which subroutines the computer should use to accomplish the task. Test your algorithm carefully to be sure it is working the way you want it to. When it comes time to actually code the program, you will find it very easy to do with the detailed planning ahead of time.

After the program is coded, test it off the air. Make sure all the functions are working as they should. You are bound to uncover many bugs during this initial testing period. When you are satisfied that the system is operating smoothly, put it on the air but be prepared to uncover many more bugs. No matter how carefully the program is written, there is always someone who will come along and enter a command that will cause the program to bomb. Hams are very talented in their ability to discover oversights in programs of this nature by entering stuff the programmer never anticipated!

Make sure that there is a way to shut the system down at a moment's notice. You are required to have a control operator monitoring the system at all times. Some means of shutting off the system on another frequency or over the phone line must be provided for. In a busy area, it is wise to use PL or Touchtone™ control so that signals on frequency will not turn on the mailbox when it is not wanted. This is also necessary when you want to limit access to the system.

On UFRC's mailbox system, there are two modes of operation: the normal mode and the privileged mode. In the privileged mode, the user can store longer messages and can use certain commands that are not available to everyone. In addition to saving on disk space by limiting the number of people who can store lengthy messages, it also provides incentive for non-members to join the club and get the priviliged-user status. The privileged mode is accessed with a PL tone and the sending of some non-printing characters during the LOGON process.

The UFRC mailbox is composed of the following hardware: an Apple II Plus computer, the Disk II disk drive, a Flesher TU-170, a Heathkit™ HW-2036A, and a 2-meter ground-plane antenna. Future plans consist of using a local repeater, WB2VTN/RPT (.64/.24), to extend the range of the system. As of now the system is closed, but it will become an open system as soon as we get enough extra disk storage to handle more users. Presently, there are about 20 active users. The system can hold about 150 average messages. You can hear the UFRC mailbox on 145.71 or the alternate frequency, 144.19. The callsign used is WA2DCS, the UFRC club call.

Please note that the mailbox design presented here is not the only possible design. There are many different ways of designing a RTTY mailbox system. Since there aren't a great many of them around, there is still much to be done in the area of hardware and software design.

More advanced systems often have additional features. For example, it is possible to include a library of RTTY art, club announcements, and ham-related news items. As quick and reliable mass-storage devices decrease in price, the capabilities of such systems will most likely increase dramatically. The ideal system would have full duplex capabilities so that the user can interact with the computer more easily. In order to do this, each user would have to use a separate antenna or a duplexer, and separate rigs for transmitting and receiving. If various regional systems link together, a large "ham database" could result. The packet communications systems are especially suited for this purpose.

The UFRC system includes such special features as a log of all activity that is on the system during the day. Also, it is possible to inspect messages left by anybody and edit or delete them. This is necessary to eliminate garbage messages and to free up disk space when it becomes necessary to do so. Examples of this are shown in Figs. 1 and 2. These functions are available only through a local terminal on the mailbox and cannot be used on the air.

Figs. 3 and 4 show a sample flowchart and a diagram of the system hardware, respectively.

If you have any specific questions concerning mailbox systems or how to set one up, please feel free to write. Also, I would appreciate hearing from other owners and users of mailbox systems. ■

William Tucker W4FXE
1965 South Ocean Drive
Apartment 15-G
Hallandale FL 33009

The Morning Beverage Antenna

If you are a coffee drinker and you work 2 meters, you'll love this antenna. W4FXE shows you how to get wide bandwidths and small size at low cost.

Recently, I needed an indoor antenna for two-meter FM operation to place on the windowsill of my high-rise apartment. The $\lambda/4$ ground-plane antenna immediately came to mind but was quickly rejected because of the inconvenience of using the required ground-plane radials. Unfortunately, the $5/8\lambda$ mobile whip antenna could not be used for the same reason.

The Half-Wave Vertical Antenna

Because the $\lambda/2$ vertical antenna does not require ground-plane radials, it appeared to be the proper choice. An endfed $\lambda/2$ vertical antenna exhibits a high impedance at its feedpoint and therefore requires a transformer device to match the impedance of a 50-Ohm coaxial-cable feedline. A parallel resonant circuit will provide a fairly good match to this antenna and the 50-Ohm coaxial cable can be fed directly to a matching position on the inductance (see Fig. 1).

There are several other methods of obtaining an impedance match for a $\lambda/2$ vertical, including the familiar J antenna which has been with us for a good many years (see Fig. 2). I remember using the J antenna during the early 30s with a "rush box" superregenerative one-tube transceiver on the old five-meter band. Another method of matching the $\lambda/2$ vertical is by the use of the gamma loop (Fig. 3), which has been successfully marketed for many years under the name of Ringo.

I first tried the parallel resonant circuit built into a small metal project box, 4" × 2" × 1½". It worked well with a 38" vertical antenna section, but was unstable mechanically and would topple over too easily. I then built a J antenna which also worked quite well, but it was clumsy and the length (57") was too long. I tried shortening the J section to 8" and used a capacitor to bring it to resonance (see Fig. 4). This also worked well but was still too clumsy and inconvenient for a windowsill. I did not try the gamma-loop type, for I knew it would not go well with the awkward mounting.

The Coffee Can

A solution appeared: Why not use a coffee can as the base of the antenna? It would fit nicely on the windowsill and, with a little weighting, would be quite stable. However, instead of using a coil and capacitor

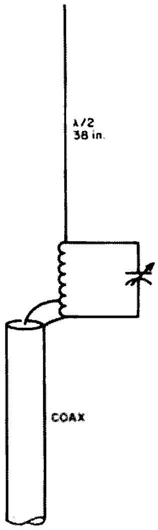

Fig. 1. $\lambda/2$ vertical antenna matched to coaxial cable, using parallel resonant circuit.

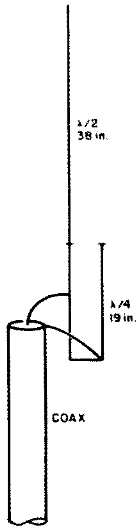

Fig. 2. $\lambda/2$ vertical matched to coax with open stub—known as a J antenna.

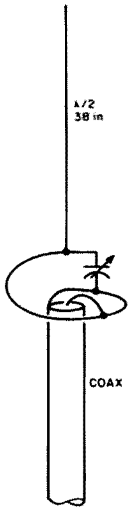

Fig. 3. Gamma-loop matching for $\lambda/2$ vertical antenna.

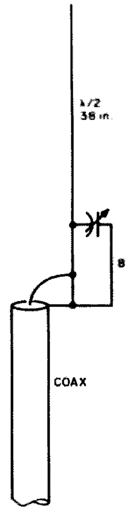

Fig. 4. Shortened J antenna.

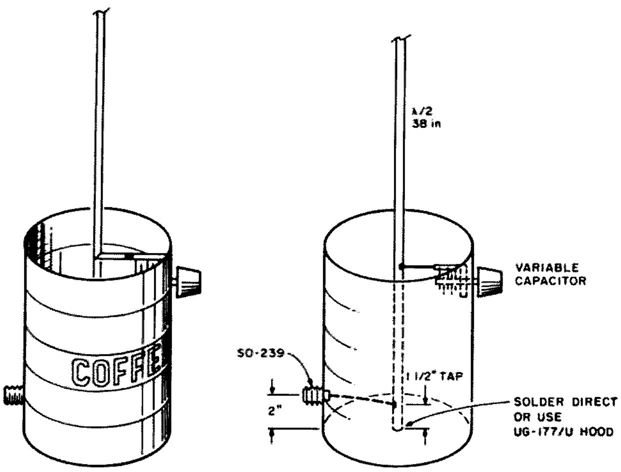

Fig. 5. The $\lambda/2$ coffee-can antenna.

as the parallel resonant circuit as shown in Fig. 1, I decided to use the *can* itself as part of the resonant circuit in a *coaxial* configuration. Being less than a $\lambda/4$ in length, I could tune it to resonance with a small variable capacitor (see Fig. 5).

The top end of the inner conductor, where it is tuned to resonance with a small variable capacitor, is a high impedance point and provides a good match to the bottom end of the $\lambda/2$ vertical antenna section. The bottom end of the can, where the inner conductor is attached, is a very low impedance point . . . comparable to the bottom shorted end of the J antenna. A good impedance match to the 50-Ohm coaxial cable can be obtained at about 1½" from the bottom end.

Usually, a coaxial resonant circuit of this type exhibits a very high Q. However, by feeding the $\lambda/2$ vertical section directly at the high impedance point and by attaching the 50-Ohm feedpoint directly to the inner conductor, the circuit is loaded down, reducing the Q considerably.

Construction

The drawing is self-explanatory. A 50-pF variable capacitor of the APC type (or equivalent) with either a screwdriver adjustment stub or a knob shaft may be used. Make certain that the rotor wiper contact is clean and makes good contact and connect it directly to the inside surface of the coffee can. Run a short, rigid copper wire from the stator plates to the inner conductor as shown. If a screwdriver adjustment shaft is used, solder a jumper wire from the non-rotating portion of the tuning shaft to both mounting studs as shown in Fig. 6. If a knob shaft is used, make the opening in the can smaller so as to make a tight fit around the shaft. This is done in either case to avoid annoying hand capacity.

The inner conductor can be made in one 43½" length so that 38" of vertical antenna ($\lambda/2$) will be exposed above the top of the can level. Copper or brass tubing, ¼-inch o.d., will result in increased bandwidth, although ⅛-inch tubing or solid hard-drawn copper, no. 8 or even no. 10, may be used.

If desired, with a little ingenuity, the antenna section can be made telescopic for convenience. An easy way to attach the inner conductor to the bottom of the can is by soldering it to a socket hood (UG-177/U) as shown in Fig. 7. You can

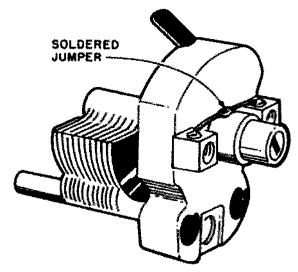

Fig. 6. APC type variable capacitor showing shaft housing jumper soldered to mounting studs.

also make an opening in the bottom of the can for a tight fit with the inner conductor and solder it there securely. With the attachment to the stator plates of the variable capacitor, the inner conductor is quite rigid.

The SO-239 socket is mounted as shown about two inches from the bottom of the can and fed with no. 16 copper wire to a position on the inner conductor about 1½" from the bottom.

Operation

The operation is quite simple. Simply place an swr meter at the antenna base and feed with any convenient length of 50-Ohm coaxial cable directly from the two-meter transceiver (see Fig. 8). Adjust the variable capacitor for the lowest swr at the most used frequency. If the swr does not dip down to a very low reading, move the coaxial-cable tap on the inner conductor up or down a little until the swr is practically at unity. You can leave the

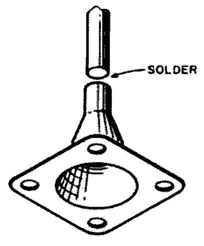

Fig. 7. UG-177/U hood.

swr meter in the line for subsequent adjustments if needed. If not, you can remove it and retune when necessary for maximum received signal strength or with maximum response on a small field-strength meter.

The bandwidth of the antenna is about 2 MHz. You should tune the antenna for a most used center frequency and when shifting frequency about 1 MHz either side, the swr should remain under 1.5:1.

Because of its size, the coffee can provides a nice, stable base. However, it should be weighted down for additional mechanical stability. I live near the beach, so I filled the can with assorted shells that were cleaned thoroughly. You can also use colored glass marbles such as those used decoratively in fish tanks. When the coffee can is filled with the above, slight retuning may be necessary.

A final note: It is good practice from a health viewpoint not to stay too close to the strong rf field of any VHF antenna . . . especially if you are using more than 10 or 15 Watts. ■

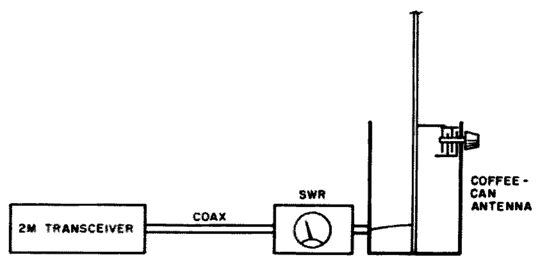

Fig. 8. Test setup for tuning the coffee-can antenna.

Try Out a Low-Level Lazy Loop

It may be only 10 feet up, but this aerial is no worm-burner. Better still, it will fit almost anywhere.

Jim Gray W1XU
73 Staff

The loop antenna is well known, with many variations including the quad loop, the delta loop, and the twin loop. Loops have a reputation of being easily tuned, forgiving of slight mismatch, broadbanded, balanced, and immune to QRN. Many antennas are really loops in disguise; if you don't believe it, consider such diverse examples as the folded dipole and the rhombic.

The "lazy loop" is basically a standard loop antenna arranged horizontally above ground, but at an unusually low height—less than one-tenth of a wavelength, for example. Before you protest that such antennas are earthworm warmers, let me recount some of my experiences.

About two sunspot cycles ago, give or take several years, I was blessed with a typical suburban lot measuring about 75 feet by 200 feet, ideal for a longwire or a collinear, antennas that need little "width" to perform their function. However, I was unsatisfied because I couldn't have that antenna farm we all dream about. You know the one: rotatable rhombics on 160 meters and that kind of thing.

Financial limitations, physical restrictions, and neighborhood censure all discouraged tall towers, large supporting structures, and *wires* (*visible* wires, at least). A lot of digging and poking in the literature kept bouncing me back to the original concept of a horizontal loop, but I could find very little information available on full-wave horizontal loops. Rhombics, yes; full-wave loops, no.

I reasoned that a full-wave loop, horizontally arranged, would use the earth as a reflector of rf energy, and the better the ground, the better the reflection. After all, vertically-mounted loops use other loops, screens, and even linear elements as reflectors, so why not the ground itself? The only drawback I could see was that my soil conductivity (which determines the quality of the "image" antenna or the reflective quality of the earth) was very, very poor. Dry, sandy soil is a poor conductor but a good absorber of rf energy. The only hope I had was that the water table was close to the surface and might provide the needed reflection before too much energy could be absorbed by the earth.

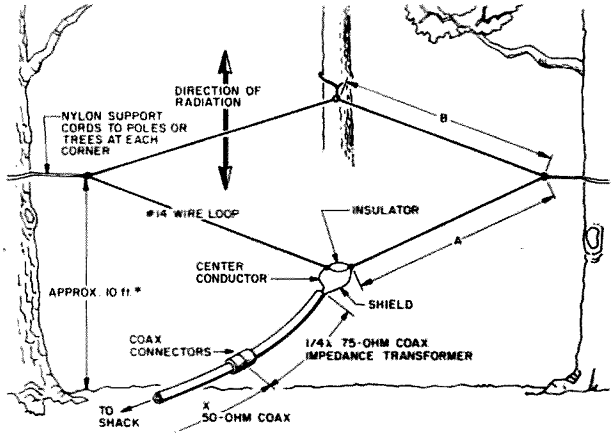

Fig. 1. "Lazy loop" 40-meter loop antenna. A = B if loop is square; 2A + 2B must equal a full wavelength (see text for formula). X = any convenient length of 50-Ohm coax to the shack. The proper 50-Ohm, non-reactive load appears at the end of the quarter-wave section of the 75-Ohm coax. Note: If nylon cord is used to support the loop at the corners, an insulator is needed only at the feedpoint.

It seemed to me that by squirting the signal skyward I could maximize the amount of rf reaching the ionosphere directly overhead and increase the amount re-reflected earthward to enhance my signal at my friends' receivers. Thus the 80-meter horizontal loop was born, with 70-foot sides, supported by TV-mast tubing at about 30 feet above the ground.

Various antenna books quoted the feedpoint impedance of a full-wave loop as being close to 110 Ohms. A quarter-wave transformer of 75-Ohm coaxial cable would change that value to about 50 Ohms, or close enough for my transmitter output impedance. So, a quarter-wave piece of 75-Ohm coax (okay, maybe it was 72-Ohm) of the RG-59/U persuasion was cut to the desired operating frequency.

The reflected power turned out to be very slight and the finals (a tube-type rig) were well-pleased. What about the forward (upward) power? Well, it seemed to come back enhanced as expected because I received lots of reports that my signal was the best ever put out by my Viking Ranger on AM phone; many reports later, I was forced to conclude that the antenna was a huge success. Stations from about 300 miles around all told me that I had greatly improved my signal and that they had noticed much less fading. I, too, noticed a big difference: The band was much more quite. On 75 and 80 meters in the summertime, you know what that means.

Everything seemed to work better than I had hoped, so I tried loading the antenna on other frequencies and bands . . . but without much success. Then I exchanged the coaxial feedline for open-wire feedline and through a tuner loaded on other bands without much difficulty. The antenna proved to have bidirectional properties and even some gain on fifteen and twenty meters. I tried changing the loop configuration (but not perimeter length) from a square to a triangle and even to a rough circle, all without any noticeable difference in performance or loading on the fundamental frequency.

I decided to bring some of the ideas along to a new homestead with a larger lot, but a set of new limitations: It is covered with trees! Not wishing to destroy the natural beauty of the place, I decided to put up the loop and use the trees themselves for support. This time, a loop for forty meters was indicated. The trees made nice, conveniently-located supports, and I was able to achieve a reasonable facsimile of a quad loop, horizontally arranged about ten feet above the ground. A possible advantage of this location was better soil conductivity, and while the trees represented a possible source of signal absorption, I hoped that the advantages and disadvantages would balance each other out, yielding a net positive result.

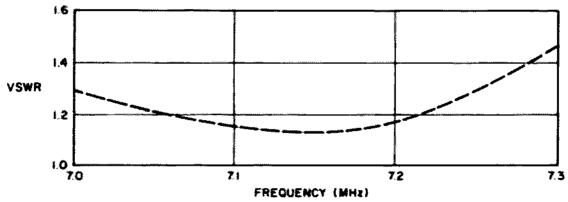

Fig. 2. Vswr at the transmitter end of quarter-wavelength, 75-Ohm matching section. (Measurement made with "MARS" bridge.)

And so it turned out. The quarter-wave matching section was cut, trimmed, and installed, and the first calls made. Results are uniformly good out to a distance of about 600–700 miles. (I have a 40-meter roof-mounted groundplane antenna for direct, switchable comparison.)

Why, then, use a loop? Well, to me, the reasons are manifold. It is easy to put up—takes maybe an hour, if you're slow. It is unobtrusive—invisible to neighbors. It gives great local performance, with reduced noise pickup. It has balanced feed and a balun is not necessary. It has simple impedance matching, and the low height means a minimum of support structure is required. Finally, it has a low cost.

Building Your Own Loop

You will need some wire, some coax, and enough room to put up the loop of your choice. Here's how you calculate the loop size (remember that you can make a square, triangle, or other polygon, regular or irregular). Use the formula $1005/f_{(MHz)}$ = total wire length in feet.

Example: You wish to put up a loop for 7.1 MHz. The formula gives a length of 141.54 feet. If you cut it to 141 feet 6 inches, you will be close enough.

The coax length is calculated by the formula: $246vf/f_{(MHz)}$ = length in feet. The vf is the coax velocity factor, which simply means that radio frequency energy travels at a different velocity in coax than it does in free space. The effect of this is that the electrical length of a quarter-wavelength of coax is different than the physical length. A common value for coax is vf = .66, and this is the value I used to cut mine. (It would be better to use a grid-dip meter to "prune" yours to the exact length needed.)

The formula for a 40-meter antenna, then, is $(246 \times .66)/7.1 = 22.87$ feet. If you cut it to 22 feet 11 inches, you'll be close enough. If that length is not enough to reach from the antenna to your transmitter, you can add any needed amount of 50-Ohm coax in series.

The coax you have cut is known as a quarter-wave matching section; it matches the impedance of the loop (110 Ohms) to the impedance of the source (50 Ohms). The quarter-wave matching-section technique requires that the matching impedance be the "mean" value between the "extreme" values. It is calculated as: $M = \sqrt{S \times L}$, where M is the impedance value of the matching section, S is the source impedance, and L is the load impedance. Thus, $M = \sqrt{50 \times 110}$, or 74.16 Ohms. As you can see, either 75-Ohm or 72-Ohm coax (or other) line would provide a good match.

Performance of the Loop

In my own loop for forty meters, I find that the swr is less than about 1.4:1 over the entire band! I know this sounds phenomenal, but I cannot measure *any* reflected power at the design operating frequency! For stations within about 500 miles or so from my QTH, reports are always in favor of the loop over my comparison vertical (Hy-Gain 14AVQ, roof-mounted with two radials per band—except 40 meters, where I use 4 radials). The signal strength difference has been from nothing to as much as 2 or 3 S-units.

For close-in stations, the loop is clearly superior; for medium-distance stations, it is sometimes better and sometimes worse than the vertical. For long-distance stations, the vertical is always better by an S-unit or two. However, there is a very interesting phenomenon, even at night or at long distances: Selective fading often drops the received signal strength, and it is nice to be able to switch antennas and bring the signal up again in strength to its former level. In fact, diversity reception is a big advantage of using a loop with another type of antenna.

As far as DX is concerned, another antenna would probably be better, although I have worked European DX with the loop and have received good reports.

All in all, the antenna is advantageous for its low cost, simple construction, and excellent performance. This weekend I plan to put up an 80-meter version. Why not try one yourself? I know you'll like it. ■

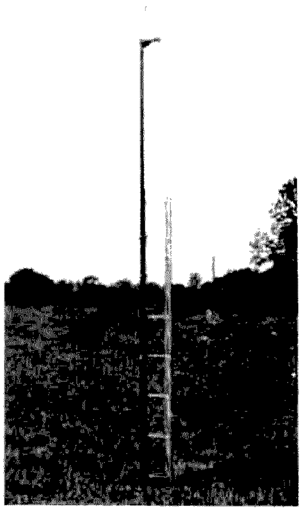
Gin Pole for Peanuts

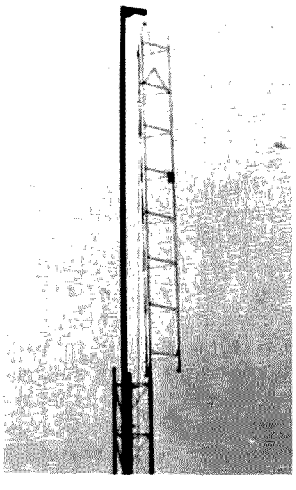
Ever pull yourself up by the bootstraps?
Build this gin pole and let it do the same for your tower.

Have you ever wanted to put up a tower that uses 10-foot sections that bolt together from the ground up, like those in the Rohn 25G tower? Well, I did. Could you have borrowed somebody's gin pole to accomplish the task? I couldn't. Did you want to pay about $150 to buy one? I didn't. So what *did* I do? I built my own for $19.15 plus a little welding of scrap iron done for me by my friend, John Boger. (The welding isn't necessary if you prefer to do some drilling and bolting.)

But I'm ahead of my story. Not wanting to re-invent the wheel, as they say, I reviewed all the back issues of *73, CQ, HR,* and *QST* magazines on hand and found only one reference to making a gin pole—in which the method of attaching it to the tower was too complicated for me. However, in my reference search I came across articles on gin poles used to erect towers by means of leverage principles, which leads me to believe that they are the real gin poles.



Initial position of gin pole with U-clamps loosely connecting it to a tower leg.



Here is a section hoisted up and the rope secured, prior to climbing and bolting to lower section.

Item	Cost
25' thin-wall black pipe, 1⅞" O.D.	$14.50
4 U-clamps, 2⅜" × 4½"	2.76
1 pulley about 3" diameter	1.89
Scrap metal	0.00
	$19.15

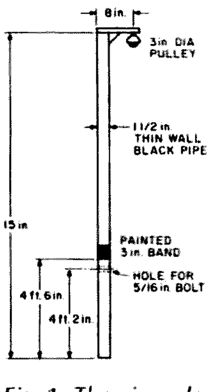


Fig. 1. The gin pole.

Gin-Pole Fabrication

The materials I purchased are shown in Fig. 1. Fifteen feet of pipe is all that is really needed, and Fig. 1 shows how I fabricated the pole.

John took a piece of 1" × 1" × 9" angle iron and welded it to the top of the pipe. He then made a metal triangle with the 90° sides 2" × 3" and welded it to the pipe and angle iron for strength. My task was to drill a hole in the angle iron for the pulley, drill a hole in the pipe for a bolt (use to be explained later), and paint a band around the pipe for an alignment mark. The gin pole

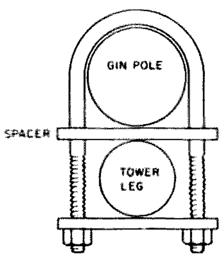

Fig. 2. Upper clamp.

weighed 25 pounds, which was light enough for one man to handle while erecting a tower.

Using the Gin Pole

Let's see how we use it, starting with the first ten-foot section of the tower secured to its concrete footing, and the rope, quarter- or half-inch nylon or manila, already threaded through the pulley on the gin pole.

Step One. With the gin pole on the ground but vertically against the tower, two U-clamps are loosely connected around the tower leg and gin pole. The upper clamp should be positioned between the first and second top tower rungs. The lower clamp should be positioned between the third and fourth rungs.

Climb to the top of the 10-foot section, safety-belt yourself in place, and lift the gin pole so that the painted band is at the level of the tower top. You will see that the hole drilled through it is at a level so that you can stick a 5" bolt through it and rest it and the pole on the top rung of the tower. The two clamps can now be tightened.

At this point it is appropriate to indicate that the two clamps are slightly different. The upper part of the gin pole cannot be snug against the tower or it will be difficult to insert the next section. A slight displacement of the gin pole from the vertical is required to prevent interference between the gin pole and the new section to be inserted. Fig. 2 shows how a spacer is inserted in the upper clamp between the pole and tower to provide the necessary vertical displacement. The spacer can be a duplicate of the outer locking bar.

Step Two. Return to the ground and tie one end of a rope to the top of the next (the second) section. From the ground, pull the second section up until it is slightly lower than its final resting place and tie the rope—see the photo.

Climb to the top of the first section again and safety-belt yourself in. You can now pull on the rope to raise the second section high enough to clear the first section, and then lower onto the first section. The second section can now be bolted to the first section.

Step Three. Climb the second section, loosely connect two more clamps (spaced on the second section as the first two were on the first section). The top clamp again has a spacer in it.

The bottom clamp on the first section can now be removed; loosen the second clamp up and let the gin pole slide down a few inches until the pulley bracket rests on the top of the second section. The other first-section clamp can now be removed.

Climb to the top of the tower, safety-belt yourself in, and raise the gin pole again so that the painted band is aligned with the top of the tower. Slip in the 5" bolt to prevent the gin pole from slipping down, and tighten the two new clamps.

You are now ready to follow step two again, and by an iteration of steps two and three and putting in the guy wires at the appropriate levels, you can go as high as the recommendations for the tower permit.

It would be very nice to say you put the tower up all by yourself, and you can. However, practical considerations, especially safety, say, "Have a ground helper as a minimum requirement!"

Some Suggestions

- All tower sections should be assembled on the ground to make sure the sections go together.
- Top and bottom of each section should be numbered or given a distinctive mark identical to the number or mark on the end of the next section to make certain they are properly assembled.
- Put a little vaseline inside the bottom of each tower leg to facilitate its sliding over the section below it.
- To permit each section to hang vertically when being mated, tie the rope under the second rung down, on each side, with the rope coming up the middle. *Align the numbered tower leg with the matching erected numbered leg before starting to raise the new section.*
- When mating sections, be sure the rope remains outside the tower sections; the rope can inadvertently be caught inside the tower leg, and it's a nuisance to have to pull the free end through the whole tower to clear it.

At completion of the work and when ready to remove the gin pole, loosen the two clamps and (as done before) let the gin pole slide down until it is resting on the top section. Then remove the rope from the pulley, tie it to the top of the gin pole, and, for safety, tie the gin pole to the tower while you climb down for a moment to remove the clamps. Be sure to wear gloves as you lower the gin pole down with the rope. Otherwise you may burn your hands from rope friction.

Temporary guying will give you a better sense of security after passing one permanent-guyed level before reaching the next permanent-guyed level. A good rope is sufficient for that purpose. It will require over 500 feet of rope to erect the 10th section of a 100-foot tower (when three-point guying at the 85-foot level), considering that you need a minimum of 200 feet of rope to get that last section up there. Have enough available for your tower height.

After putting up 370' of tower by this method, I found that it's easier than I had thought. You will, too! ■

Coax Connector Workshop

Tracking down feedline-related problems can make strong men cry. By starting out right, you can avoid hassles.

Picture this setting: You're sitting in the shack one evening having a good rag-chew with some friends when suddenly your whole station goes bonkers. You wonder what happened.

You check around the shack. Your rig seems to be putting a good signal into the dummy load and all the other connections look good. Yet, somehow, the signal has just gone away.

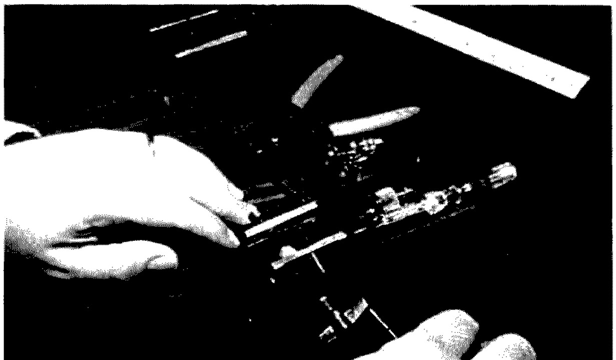
Sitting there, pondering the problem, you think: "It must be in the antenna—it can't be anywhere else. After all, the coax is new, I installed it only last week, and all the fittings and connections are okay!"

So, you're off the air, with no signal, and the next weekend comes. You check out the antenna, but everything seems okay there, too. What's the problem? "It has to be in my rig because everything else is okay. My meter is just probably giving me a false reading into the dummy load!"

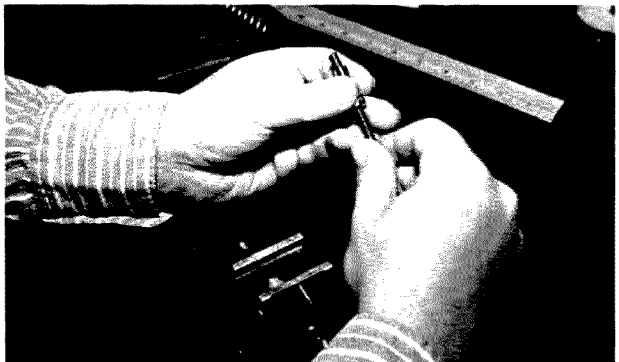
But, wait a minute! Before you haul out the rig's shipping carton and send it off to the manufacturer, there may be one area that you've missed.

Remember that new coax you just installed? Have you checked it out, too? The answer to this one is probably no, because you know how to cut coax, right? Well, just to be sure, check out the coax, too!

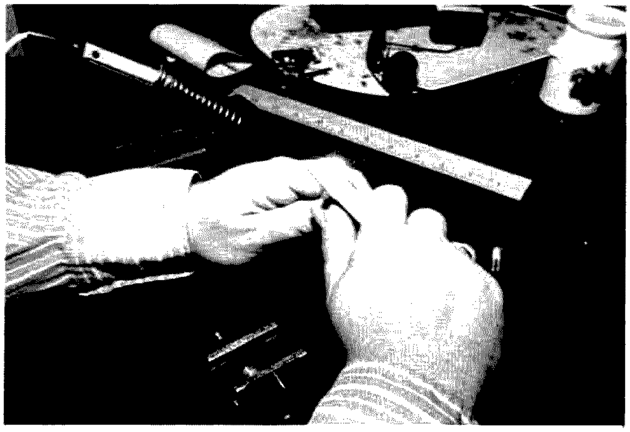
"Okay," you might think, "I might as well check out the coax, too, although it can't be bad. I know what I'm doing with coax!" So, you take the coax down and check it with your VTVM or DMM and you see that there's no continuity. "Something's fishy here!" you



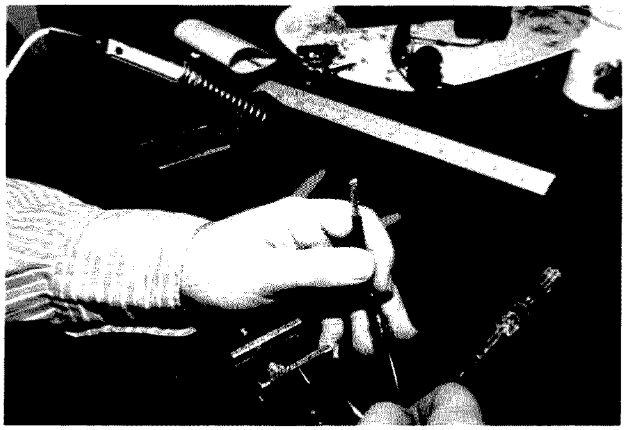
It's always a good idea to lay out the tools and parts you will need to cut coaxial cable before beginning the operation.



The first step in preparing this RG-58 cable for cutting is sliding the UG-175 adapter over the cable. This allows the use of a PL-259, which is actually sized for RG-8/U coax.



Cutting the outer covering of a piece of coax requires a sharp knife and a firm but gentle score around the plastic covering. If you cut too deeply, you risk cutting the outer braid of the coax.



Once the layer of covering material is removed, you will find the tightly twisted shield braid exposed. Here you can see the exposed braid and the UG-175 adapter.

think. You then check it out for shorts, and instead of reading infinity, your meter gives strange readings.

Voilà! You've just solved your problem. The coax was improperly cut.

Improper coaxial cable preparation is probably responsible for more problems in amateur radio than any other single cause. Unless you buy your coax precut with the fittings installed, then chances are one time or another you're going to run into problems with poor cable connections.

This need not be the case if you take some time and work slowly and thoroughly. Proper preparation of coaxial cable and the fitting of the connectors is a relatively easy, straightforward job.

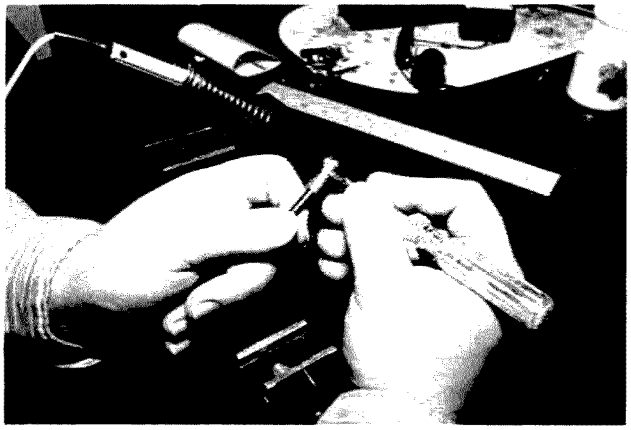
The tools needed for this job include: a sharp knife, hobby knife, or razor blade; an awl, sharp scribe, or ice pick; the cable; the fittings (PL-259 or BNC) and adapters (if needed); about a 60-Watt soldering iron (it can be less, though); and solder.

Once you have the tools laid out, it's time to begin the actual process. The first step involves slicing through the outer jacket of the coaxial cable. Whatever you do, don't carve the cable like it was a turkey because you're going to score or nick the outer shield braid of the cable; if you do this, then you're on your way to a short. So, be gentle when you first slice into the outer jacket of the cable. Just slice it far enough to expose the inner braid. Once you have done this, the jacket should slip right off and expose the braid itself. Remove about 3/4" of the outer jacket.

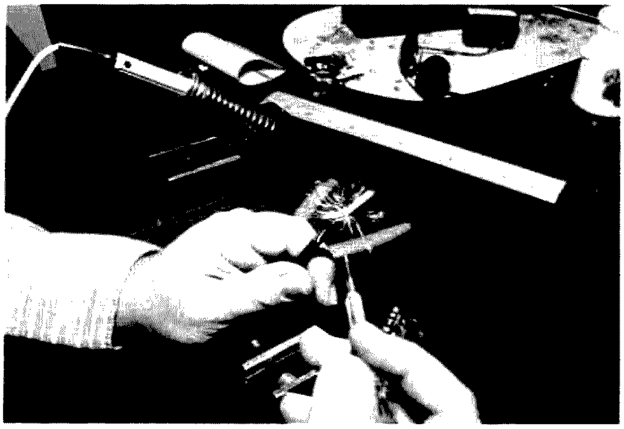
The braid is another area where many amateurs make mistakes. Too often the braid is merely pushed back down over the cable to expose the inner dielectric. Or, worse, a hole is made in the braid and the inner conductor is merely pulled through. In some cases, this is fine, but in most cases, it isn't. What is needed is patient debraiding of the shield braid.

But, before you get to this point, it is wise to install the various fittings which belong on the cable. This includes the barrel of the PL-259 and the adapter (UG-175 or 176) if you are using cable that's smaller than RG-8/U. I like the Radio Shack mini-foam RG-8 myself. The beauty of it is that it is nearly as small as RG-59/U, but is much less lossy.

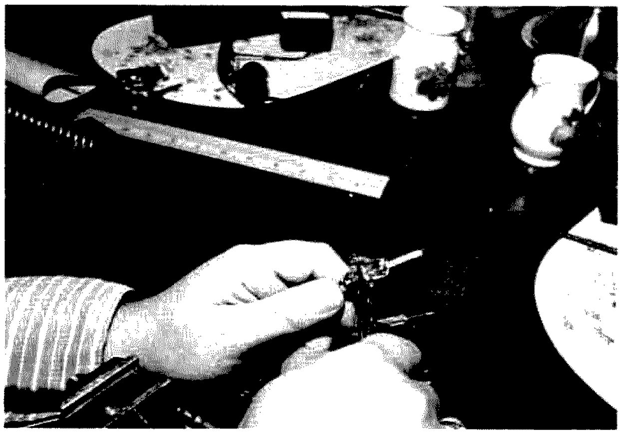
Once the fittings are installed, wiggle the braid a bit to loosen it from the in-



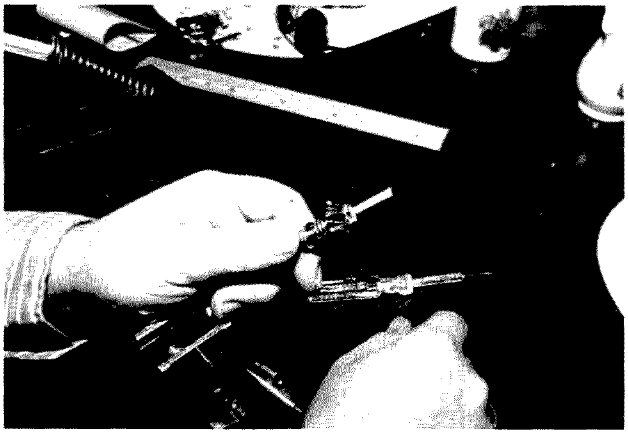
The next step in preparing coax is carefully debraiding the outer shield. For this you will need a sharply pointed scribe, ice pick, or other pointed tool.



When you have finished debraiding the outer coaxial shield, it should look like this. Notice it is fanned at roughly a 90° angle. This fanned braid is then smoothed over the adapter and trimmed.



After the coaxial cable's outer braid is smoothed over the adapter, it is then trimmed. It should be trimmed so the cable covers about 50 percent of the adapter's barrel. A pair of mini-snips makes short work of this.



With the shield braid trimmed, the soon-to-be-completed coaxial cable fitting should look like this. The trimmed braid is smoothed over the adapter and the center conductor's insulation is exposed. The installation should look like this. One note here, even though it is not shown: The screw-on PL-259 barrel is installed before the UG-175 is installed on the cable. This barrel allows the unit to be mated to a female SO-239 connector on the back of a rig. A spare is on the table.

ner dielectric. Then gently insert the awl (scribe or pick) and start to unravel the 3/4" of exposed braid.

To debraid the cable, follow the winds of the strand bundles. Take your time and don't nick or break them because you run the risk of a short if you do. The whole job, by the way, should only take 10 to 15 minutes once you're skilled at it. Yet, however long it takes, this is one of the most crucial parts, so take your time doing it.

After the cable is debraided, spread the braid strands out at a 90° angle from the cable itself. Then take a pair of scissors and trim the braid to about 3/8". (If you're using smaller cable and need the UG-175 or 176 adapter, move it up flush with the end of the outer covering.)

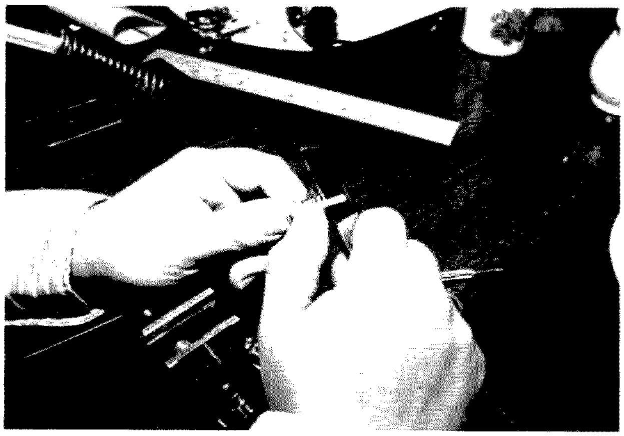
Next, take your knife and gently slice into the dielectric. All you have to do is score the dielectric and pull on it. The piece of dielectric should just slide right off the center conductor. You have to score it roughly 1/8" above the point where you've debraided the outer shield.

Once you've got the center conductor exposed, if it is stranded, twist it into a tight bundle and tin it with a little solder.

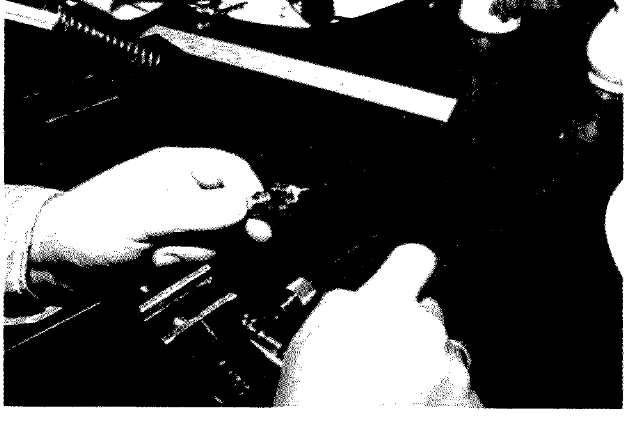
At this point, you're just about ready to slide the body of the fitting over the prepared end of the cable. Carefully take the plug body and insert the tinned center conductor into the shaft of the plug body.

With the center conductor inserted, the next step is to twist the fitting over the end of the RG-8/U. While doing this, you also have to turn the fitting to make sure that it seats properly. You have to exert a fair amount of pressure to do this, but it should be done easily without the aid of tools. Remember, those strands of copper in the outer shield are gentle beasts, so don't use brute force.

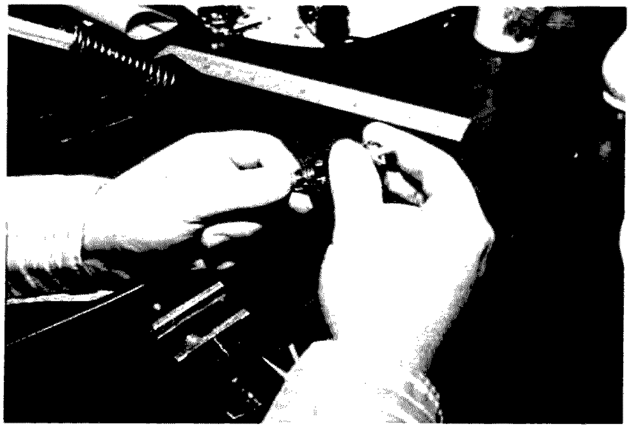
At this point, you're nearly ready to go. It's here that the soldering iron comes into play. In the PL-259 connector, you'll notice four holes in the shaft body. These are soldering holes. It is through these that you connect the outer shield to



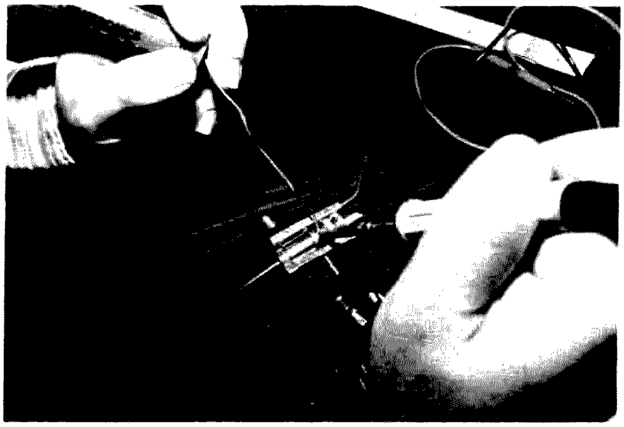
Trimming the center insulation requires careful cutting with a sharp blade. You must cut deeply enough to slice through the plastic insulation material, but not so deeply as to cut the center conductor itself. This takes practice.



With the center insulation removed, the prepared end of the coaxial cable should look like this. Notice that the center insulation is not trimmed to the same point as the shield braid. This is important because it maintains an insulated area between the braid and shield and prevents shorting.



With the cable end prepared, the next step is to install the PL-259's center fitting. This should easily slide over the UG-175 and it will then be screwed snug.



The most crucial part of the PL-259 installation is soldering the plug and coaxial shield. If you have done the installation properly, the coaxial braid should appear through the four solder holes in the body of the PL-259. Don't hold the iron here for a long time because you chance melting the little insulation left between the braid and center conductor inside the plug body itself. This means not using a low-wattage iron. A good 30-60-Watt iron should be able to cope with this task easily. This soldering also provides a good ground, which is necessary for coaxial cable.

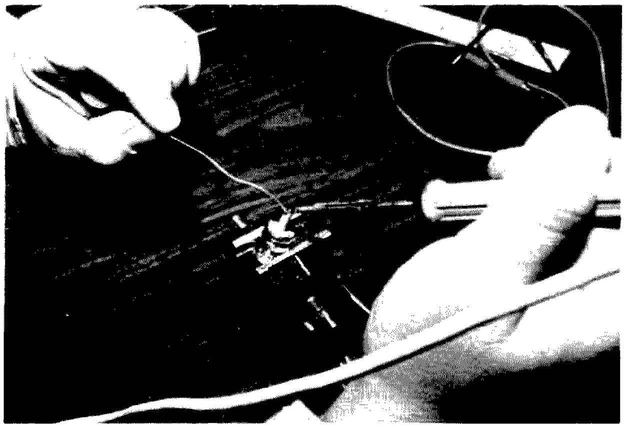
the fitting. These provide the ground for the outer shield.

Making sure that the soldering iron is hot enough and using a pointed soldering tip, apply the iron to both the hole and the shaft of the plug body. You do this by angling the iron slightly. After a couple of seconds, the braid and body should be hot enough to take the solder for a good joint. Don't overheat the braid (though it's a wonderful conductor of heat *away* from the area where you're working), because you can damage the nearby outer jacket easily, and *most importantly*, you can heat the braid to the point of melting the inner dielectric, producing an instant short! Continue the soldering process until all the plug holes are filled with solder and the connections are good. And, once you have completed this step, it's time to move on to the tip of the fitting itself.

What you'll find here is the tinned center connector inside the tip of the plug. Merely apply your iron to the tip and the center conductor and then run in enough solder to fill the shaft. Wipe it quickly with a damp sponge to remove the excess rosin.

The next step is screwing the barrel of the fitting over the body of the body itself—and you've completed the job.

If you're using smaller coax and need the UG-175 or 176 adapter, there's an extra step. You trim the braid as in using the larger-sized cable, but then you screw the fitting body over the adapter. The braid of the outer conductor will be visible through the solder holes. Once this is secure, then you solder through the plug holes just as with normal RG-8. The rest of the procedure is the same.



The last step, after the plug has cooled from the first round of soldering, is running solder into the center conductor pin. This is a hollow opening in the tip of the plug through which the center conductor should appear if it has been installed correctly. It is necessary to fill this totally with solder.

The final step in the installation of coaxial fittings is checking them for both continuity and shorts. Once you have fitted plugs to both ends of your cable and finished the work (yes, it can be tedious), take your VTVM or DMM and run these checks. To check for continuity, first set the meter to read resistance and connect the probe leads to the outer barrels of the plugs on either end of the coax. If there is continuity, you should have a zero reading on your meter. Repeat this process with the center connectors.

To check for shorts, attach one of the probe leads to the outer barrel of one plug and the other probe to the center connector of the same plug. The reading you should obtain is infinity. If you don't get the proper meter readings, then you've got a short somewhere (probably in one of the fittings) and you're going to have to remove the fitting and start all over again.

However, if you've taken your time, you should find that the readings are okay and you're ready to install the coax. That's all there is to it.

Making proper coaxial fittings may not be the most glamorous part of amateur radio, but it is one of the most important. The coax, after all, is what carries your signal to and from your antenna, and without a signal, even the best station and equipment is pretty much useless. ■

Make Your Noise Bridge Even Better

Use these shortcuts for easy calibration and give your transmitter 1:1 vision.

Cocoa Beach FL 32931

While reading the excellent article entitled "QRM-Free Antenna Tuning" in the August, 1981, issue of *73 Magazine*, I was particularly struck with the ingenious associated circuitry of Fig. 3 that allowed the noise bridge to be used also as a QRM-free tune-up device. The authors recognized a problem and offered a solution to it that will be of great benefit to all amateurs. Even more important, the technique described will prevent serious damage to your transmitter by ensuring that it goes directly into a matched load. You will keep your finals cool!

However, I did notice an error in the schematic. Also, I was able to calculate an alternative method of calibration that eliminates the need for standard inductances yet allows for a theoretically exact calibration of the entire reactance scale. My equation allows the bridge to be directly calibrated for the reference frequency of 1 MHz, thus eliminating the need to refer to either graphs or cumbersome equations. However, the graphs and equations have been shown here for information purposes.

A Correction

First the error should be corrected. In Fig. 2 of the referenced article, the 68-pF capacitor should be in series with the antenna jack as shown in Fig. 1 of this article, and *not* connected to ground as originally shown. The sectional schematic shows this correction and also has the parts labeled for identification purposes.

In order to obtain an exact calibration, rather than using the mirror-image method previously described, it will be necessary to use some small fixed capacitors for standards. Ordinary 5% silver micas or their equivalent will work just fine. The values of 10, 20, 30, 40, 50, 60, and 70 pF are used to obtain the basic calibration points. Small values of capacitance can be paralleled to obtain larger values; for example, a 20 pF in parallel with 30 pF will give a 50-pF value.

When using these standard calibrating capacitors,

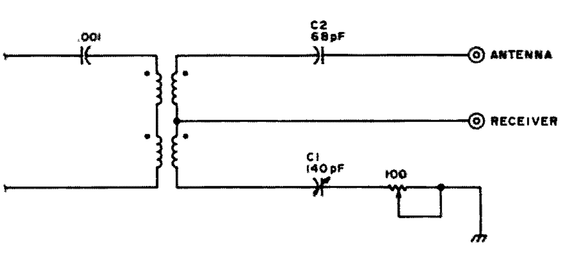

Fig. 1.

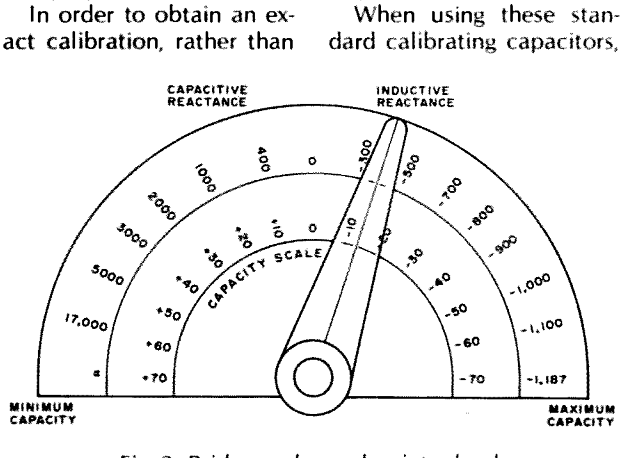

Fig. 2. Bridge scales and pointer knob.

the leads should be kept as short as possible to avoid undesirable lead inductance. As a further method of diminishing the lead-inductance effects during calibration, I prefer to do my own calibration at a low rather than a high frequency. In my own experimentation, I have used a calibration frequency of 3.75 MHz and found it to be very satisfactory. If a bridge is carefully built, the calibration should be satisfactory for the range of 160 to 6 meters.

Fig. 2 shows an outer scale in reactance and an inner scale of the standard capacitances used. (The inner scale is shown to help understand the technique used and is not needed when you actually use the bridge to measure reactance.)

Calibration

The first step is to calibrate the resistance dial of the bridge. The method previously described is correct, and no further comments are needed. When doing the reactance calibration, a 50-Ohm resistance should be connected to the antenna jack of the bridge. For my own purpose I just soldered a 50-Ohm, ¼-Watt resistor inside of a matching plug, keeping the leads as short as possible inside of the jack.

The knob on the variable capacitor should be so positioned that the capacitor is fully meshed when the knob is pointing to the right or the maximum capacitance marking on the scale. Then when the knob is pointing up to the zero point on the scale, the capacitor will be at half capacitance. With the 50-Ohm resistor connected, null the bridge. The reactance dial should be quite close to the mechanical half-point of the variable capacitor. This is called the original null point, and here C1 will have a capacitance value of 68 pF to match that of the 68 pF of C2.

Nulling is obtained when the total impedance of one side of the bridge is exactly equal to the impedance of the other side of the bridge. If the null point is quite close to the mechanical center point of the capacitor, the values can be brought to coincidence by slipping the knob shaft a few degrees one way or the other so that the knob reads zero at the electrical null. This technique will not affect the basic accuracy of the bridge when it is finally calibrated.

It could happen that if the maximum value of C1 were higher or lower than the specified value of 140 pF, the electrical null and the mechanical half-mesh point would be off more than a few degrees. In this case, the value of C2 would have to be changed to bring these two points more closely in line. If this is done, then the actual value of C2 should be recorded since its value is used in the reactance equation shown later on. If, by chance, there is a large, unexplainable difference between the electrical null and the mechanical half-mesh point, the circuit should be checked for wiring errors.

Now that the original null has been accomplished, the bridge can be calibrated. Start with a 10-pF capacitor and connect it across C2. The total capacitance of this circuit will now be 68 + 10 = 78 pF. This means that to null the bridge, the capacitance of C1 will have to be increased to 78 pF. At this null point, mark the capacitance scale as −10 pF. Now remove the 10-pF capacitor from across C2, replace it with 20 pF, and obtain and mark this new null point on the capacitance scale. Repeat this procedure until the right half of the scale is calibrated in capacitance values.

The left-hand side of the scale is calibrated in a somewhat similar manner. Place the 10-pF capacitor across C1. This means that for the bridge to be in balance, the capacitance of C1 will have to be reduced 10 pF. The null point on the scale is marked +10 pF. The 10-pF capacitor is removed and the procedure repeated for the larger sizes of calibrating capacitors until the scale is calibrated.

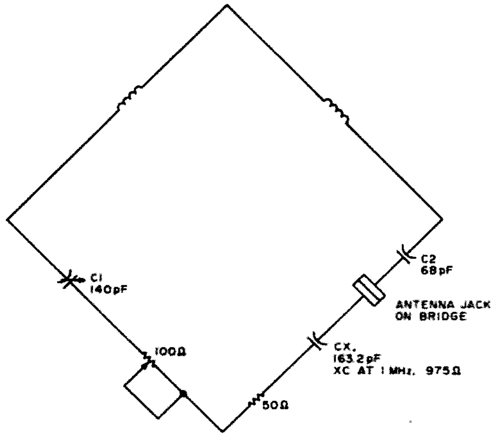

Fig. 3.

The bridge is now calibrated in terms of +C and −C, and all that is needed now is to relate these values to values of X_l and X_c so that the bridge scale can be calibrated directly in terms of reactance. And even though the bridge was calibrated at a frequency of 3.75 MHz, a bit of calculation will enable us to calculate the scale reactance values at our originally stipulated frequency of 1 MHz.

For illustrative purposes, let us pick a series load of 50 Ohms and a capacitance reactance of 975 Ohms at 1 MHz and connect them across the antenna jack of our bridge. The schematic of Fig. 3 will make it easy to follow the mathematics involved. The actual value of the capacitor at 1 MHz is calculated and found to be 163.2 pF. The equation used is C = 1/2πFX, and because F is in MHz and C is in pF, 1,000,000 is needed in the numerator. C = 1,000,000/(2)(π)(1)(975) = 163.2 pF.

From the circuit of Fig. 3, it can be seen that the 68 pF of C2 is in series with the 163.2 pF of the load, and the resultant capacitance of the two is from our series capacity equation, C = (68)(163.2)/(68 + 163.2) = 48 pF. To obtain a null at this point, our variable capacitor would have to be set at a capacitance of 48 pF, which is actually its original null value of 68 pF minus the 20 pF calibration point for the left-hand side of the dial. (I hang my head and confess that the original value of 975 Ohms of reactance was chosen to keep the math easy and make the result come out exactly at the 20-pF point on the scale. This is what is called a planned coincidence!)

By now some of you will be saying, "Hey, if I have to go through all of that stuff every time I want to make a reactance measurement, forget it!" I couldn't blame you. But by sitting down and combining all of the foregoing calculations in a single equation, it is easily possible to just use the scale calibration values and obtain reactance values. And the basic equation is this: X = (−j) [(1,000,000)(dial setting)/(2)(π)(C2)(C2 − dial setting)(frequency in MHz)].

(The term (−j) was added so that all values calculated will come out in the conventional engineering notation, so that capacitance reactance is −j and inductive reactance is +j.)

And now we are better

Dial	Capacitive Reactance	Dial	Inductive Reactance
0	0	0	0
+10	403	−10	300
+20	975	−20	532
+30	1848	−30	716
+40	3344	−40	867
+50	6501	−50	992
+60	17,550	−60	1097
+68	∞	−70	1187

Fig. 4.

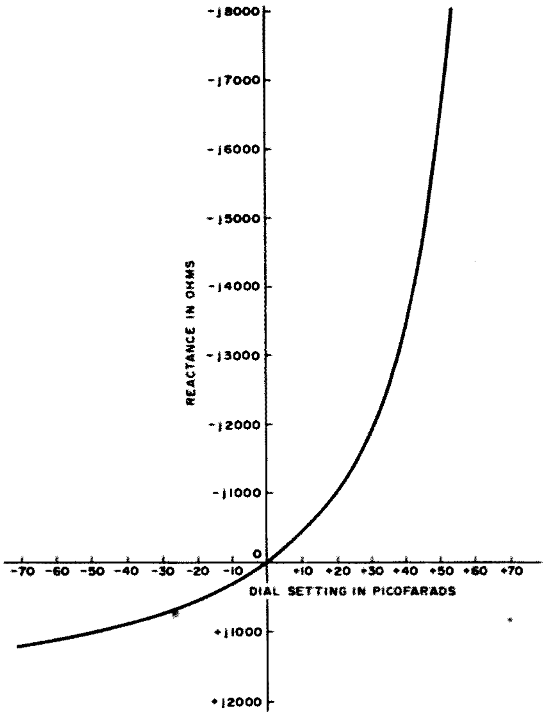

Fig. 5.

able to see that because inductance reactance is opposite to capacitance reactance, the right-hand or inductive reactance side of the scale was marked in *minus* (−C) values.

The equation is easily checked numerically by just putting in the previous values and we shall see that we will wind up back with our value of 975 Ohms: X=(−j)(1,000,000)(+20)/(2)(π)(68)(68−20)(1)= −j975 Ohms.

It will be evident that the sign values for the capacitive scale should be observed in the equation when it is used. This can be illustrated by assuming a null reading of the C scale of −30 pF. This indicates the reactance will be inductive. The calculation is as follows: X=(−j)(1,000,000)(−30)/(2)(π)(68)[68−(−30)](1)= +j716 Ohms. And if we were calibrating our scale, the −30 value of capacitance could be marked as 716 Ohms.

And now to save everybody a lot of time calculating values either for the scale or the construction of a graph, I've included a table of values (Fig. 4) and the graph (Fig. 5) showing values of reactance vs. dial settings of plus and minus C.

The bridge is very easy to use when measuring impedance. Just connect your unknown value of impedance to the antenna jack of the bridge, make your null, and read your resistance and reactance scales. Take your reactance value and divide it by the frequency in MHz at which you are making your measurement, and you have your reactance value in Ohms. The resistance dial does not have to be divided by frequency as it reads correctly independent of frequency.

There is one easy check that you can make to show if your bridge is frequency-sensitive. It theoretically should not be, but naturally all pieces of equipment have distributed capacitance and lead inductances which make theoretical values deviate from the ones measured. The best test is by using a simulated load of a capacitance and resistance in series, and make a null measurement at some low frequency (say, 3.75) as we had originally done. Now, without touching the bridge, increase the measuring frequency to some high value (say, one of 10 or 15 meters).

You may not believe this at first, but the bridge will stay at a null position without having to move either the reactance or resistance dials. This indicates that you have a very good bridge. Practically, you might find some slight deviation in the dial settings, but they should not be excessive. This rather interesting and very useful test result is because the dial was calibrated with standard capacitances and, after all, a capacitance at 3.75 MHz has the same capacitance at 10 or 15 meters. Try it, and you will see how useful this test is in evaluating a bridge unit. It will uncover stray, unwanted capacitances and inductances and will also quickly tell you if you have some basic problem when you first build your bridge.

Easy Tune-Up

As I mentioned earlier, the auxiliary circuit of Fig. 3 of the original article is extremely useful as it allows you to adjust your matching network to exactly 50 Ohms, so that after you have tuned up your transmitter into your dummy load and switched over to your antenna circuit, your transmitter will have an swr of 1:1 and you are ready to go on the air. Tuning up using a matching network directly may result in a period of high swr. This can damage your equipment or, in the case of the newer transistorized rigs, cause you to lose power. So, just tune up your rig into the dummy load at fifty Ohms, then use the auxiliary circuit, tune up your matching network with the bridge, and switch over; you are ready to go on the air.

There is one final note of caution: *Never turn on your transmitter if your auxiliary switch is in position 2 or 3.* If you do, you may see some smoke! In fact, to stress this point, the instructions that accompany Palomar Engineers' noise bridge combine the warning with a picture of a noise bridge buried in a graveyard with a gravestone marked "R.I.P., R-X Noise Bridge."

Using a four-layer rotary switch, a transmitter defeat circuit could be added. Every transmitter's turn-on capability varies with the design circuit, so this protection will have to be left to the ingenuity of the individual amateur. The circuit would have to be so designed that the transmitter would operate only when the switch is in the number one position.

If you decide to buy a commercial bridge, it can be used with the auxiliary circuit. Thus, you will reap all of the advantages of having a means of measuring impedance and a means of tuning up without putting any QRM on the air, and you can tune up your rig without any chance of damage. The original article is well worth every serious amateur's thought and consideration. ■

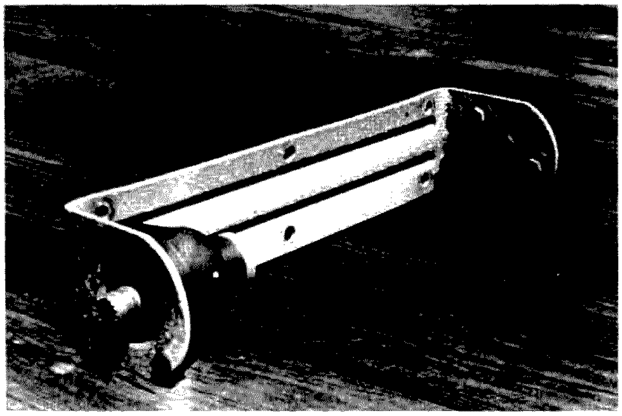
Antenna Refinishing the Easy Way

When a good vertical begins looking like a rusty downspout, it's time for some maintenance. Here's how K6EW saved a hamfest special.

Sam Creason K6EW
2940 Arlington Avenue
Fullerton CA 92635

At a recent ham swapmeet, I was able to buy a used 18AVT/WB trap vertical antenna for about half the cost of a new one. However, it had been exposed to Los Angeles air for several years, and therein lay a problem. The 18AVT/WB consists of several traps, pieces of aluminum tubing, top-hat radials, and a short metal whip. These parts are assembled telescope-fashion and held in place by compression clamps, nuts, and bolts. Over the years, the smog-ridden air had attacked the metal, making for poor contact between adjoining surfaces. Furthermore, the spacing between traps depends upon whether the antenna is to have minimum swr for phone or CW subbands, and whether it's to be mounted on a rooftop or on the ground. Without an instruction sheet, I had no way to determine the spacings. Finally, like any ¼-wave vertical, the 18AVT/WB requires some sort of ground plane or system of radials. Again, I was at a loss without an instruction sheet.

A letter to Hy-Gain, the manufacturer, brought a brochure on the antenna but no instruction sheet. A letter to *73*'s "Ham Help" column did the trick (thanks to WB4TCP, WB6JOP, N8ECR, WD8JFF, KØYEH, and WAØITU). For someone who is in the same position as I was, the dimensions for the 18AVT/WB and radials are given in Figs. 1 and 2, respectively. Two radials per band are required, and they must be insulated in a rooftop installation. "Egg" insulators are handy for this. Extensions to the radials for attaching to guy points must



Base of antenna. Bottom piece of aluminum tubing passes through the insulated opening (right) and rests on the insulated support (left).

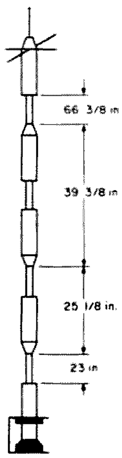


Fig. 1. Dimensions of the 18AVT/WB for CW, roofmount. (Not to scale.)

Band	**Length**
40	37′ 0″
20	18′ 7½″
15	11′ 10½″
10	9′ 10″

Fig. 2. Dimensions for radials for the 18AVT/WB.

be insulated from the radials and should be broken into shorter segments than the radials.

Once the antenna is disassembled, cleaning the various joints requires a few sheets of medium-grit sandpaper, two or three dowels ranging from ⅜" to ¼" in diameter to support the sandpaper against inner surfaces, and some elbow grease. Each mating surface should be sanded until it has a smooth satin surface. Areas where the radials make contact should also be sanded.

Having cleaned, reassembled, and installed my refurbished antenna, I tried making a contact, but to no avail. The photograph shows what I'd forgotten to clean! The lowest piece of aluminum tubing slips over an insulating block which provides vertical support. On top of the block is a disk of aluminum which is a snug fit inside the tubing and provides electrical contact with the radiating portion of the antenna. A setscrew through the tubing forces the disk against the opposite side of the tubing.

Cleaning the joint was no problem, but because the wall of the tubing is rather thin, there are only a few threads to engage the setscrew. Unfortunately, I stripped these threads while reassembling the antenna. However, a 10-32 screw saved the day. It's a little larger in diameter than the original setscrew and the threads are not as coarse. It served nicely as a self-tapping screw in the softer aluminum.

Results with the refurbished vertical have been encouraging. Although I use an HW-8 (about 3 Watts out), I've had no problem at all making stateside contacts. Finland and Japan were the best DX in the first three weeks of operation. I suspect that my vertical will get a yearly cleaning. ■

NEW
FOR THE TRS-80*
COLOR COMPUTER
MORSE CODE

Here's a way to turn your Color Computer into a complete CW Morse Code terminal.

—KA9FSQ CW MODEM Interfaces the computer to your transceiver via the ROM-PAC slot.
Cartridge: $50.00

—Three CW programs to choose from.

—KA9FSQ TRANSLATOR (Machine language)
TX programmable from 5-60 WPM, RX to 60 WPM. Features split screen operation, a 255 character keyboard buffer, and automatic CQ using your own call letters.
Cassette: $24.95

—W9AV TRANSLATOR (Extended Color Basic)
TX programmable 5-50 WPM, RX to 30 WPM. Includes 9 message memories, and a CW practice mode which sounds over your TV.
Cassette: $14.95

—W9AV QSO ROBOT (Extended Color Basic)
TX programmable 5-50 WPM, RX to 30 WPM. Use the keyboard or Auto Mode. Makes complete CW QSO's without human intervention including exchange of calls, RST, QTH, and names. Also keeps a log.
Cassette: $19.95

PAPUA NEW GUINEA

Siegi Freymadl P29NSF
PO Box 165
Rabaul
Papua New Guinea

During January, band conditions were very poor; the 10m band appeared dead most of the time or was open only for a short while. I have been having biweekly schedules with my friend Doris N5CFP, in Garland, Texas, for more than two years, but during January we missed out on a number of occasions due to bad conditions. At times we were pleasantly surprised when she called at 2230 GMT and signals were good, but by 2300 the band closed again. We have now arranged for split frequency operation as 15m seems to be more reliable. But on that band, too, the noise level is very high.

Eighty-meter nets are still being run within Papua New Guinea. The Highlands net meets every Monday night on 3560 MHz at 0930 GMT, and another net runs from the national capital, Port Moresby, on Thursdays at 0930 GMT, also on 3560 MHz. The nets are badly attended at present, with only three or four stations checking in. According to Peter P29NUK, 80m in Port Moresby is impossible at the moment—the noise level being unbelievably high—and therefore none of the amateurs from the national capital are able to participate.

One event that the Papua New Guinea Amateur Radio Society is involved in is the Papuan Safari Road Rally, which is held annually over a long weekend marking the September 16 anniversary of independence. The rally has been going since 1979. It is organized by the South Pacific Motor Sports Club, and members of the PNGARS provide communications between checkpoints for scoring and safety. For the occasion, they are granted third-party privileges, to enable them to pass on third-party traffic on behalf of the Sports Club. Normally, third-party traffic is not permitted in PNG. The independence rally runs over three days and nights and attracts international drivers and cars.

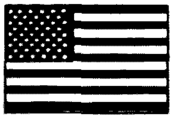
AOCP (full call) examinations were held in PNG on Tuesday, 15 February, at the same time as in centers in Australia. It is once again possible to sit for CW exams in the center nearest to one's QTH, without having to go all the way to Port Moresby. Apparently, a radio inspector to give the examinations is now available to do the rounds again, and he flies to the towns where candidates have applied to sit for exams. It was the lack of a radio inspector that made it necessary for candidates to fly to Port Moresby and not a lack of funds! Now I no longer have an excuse for not attempting the exam.

Margaret P29NUN, "the nun on a broomstick" from Kefama Catholic Mission near Goroka in the Eastern Highlands, will be attempting the full call theory exam this time. I wonder what will happen to that very appropriate callsign when she upgrades? Sister Margaret is an Australian Sister of Mercy and has become a very well-known ham since gaining her license in February, 1981. Her QSL card depicts a caricature of a nun riding a broomstick. Her black habit is billowing out behind her, displaying spotted bloomers. The rig is strapped to her back, earphones are clapped over her ears, and a microphone is clutched tightly in one hand while she holds on to the broom with the other. The card was designed by Bob P29NBF, another ham from Goroka. Needless to say, that card is a prized possession of amateurs all around the world!

Bob P29NBF and his XYL bought a yacht in Cairns (Australia) towards the end of last year and sailed her up to PNG in November. During the trip, Bob maintained daily radio contact with Sister Margaret. Unfortunately, Bob is off the air at the moment, as his radio equipment was damaged in the boat.

The hottest news on the amateur bands at present is, of course, VK0HI—the Heard Island DXpedition. In spite of checking the bands every day, I have not yet managed to work Heard Island. I have heard them on 20m on a number of occasions, but of course that is out of bounds for Novices. My hopes are centered on Jim VK0JS and his XYL, Kirsti VK0YL, who finally arrived on Heard Island around February 9th after having been delayed by various problems. Jim was P29JS, and he really put P29 on the map with his activity. Several years ago, he "went finish" from PNG and took up residence on Norfolk Island, where he married Kirsti, formerly a radio officer on a Swedish ship. Jim is VK9NS and Kirsti VK9NL, but they frequently go on DXpeditions. I should be able to get a contact with Heard Island with Kirsti and Jim there.

I have had a letter from Ron ZL1AMO asking whether a CW operation in P29 would be sought after. I told him that such an operation would certainly be very much in demand and to come on over. I have been asked many times for a CW contact but always had to decline, as I don't even have a key. A real pro like Ron would therefore be a godsend!



GUAM

James T. Pogue KH2AR
68 Banyan Circle
FPO San Francisco 96630

On May 20th, 1976, super-typhoon Pamela screamed across the island of Guam with 170-mph winds. Eighteen hours later, Pamela had left in her wake one islander dead, many injured, and over 30,000 people stranded by floods from 33 inches of torrential rainfall. Over 80% of the island's buildings were destroyed and property damage exceeded $400 million.

A *New York Times* story a few days later stated that the island's communications had been "virtually destroyed." Fortunately, Guam's hams responded to the challenge and helped provide vitally-needed emergency communications. Stationed at key villages throughout the island, they assisted public officials and augmented existing public emergency services. Although the local repeater was knocked off the air due to a massive power loss, 2 meters was still the most active band during the emergency. Messages were also relayed off-island by several HF ham stations with emergency power generators.

Today, the emergency communications system on Guam is constantly striving to be ready to serve the island population. Emergency coordinator Carl Wegner KG6JKV is responsible for organizing and keeping the emergency plan current and operational. The only repeater on the island, a 25-Watt, .34/.94 machine, is located at Carl's home in Barrigada Heights, approximately 750 feet above sea level. Covering roughly 75% of the island, backup battery power can provide over 24 hours of service in the event of a power outage. Dick Takahashi AH2A has also donated a 5-kW butane generator that should soon be installed, giving virtually unlimited service life to the repeater in an emergency.

The Marianas Amateur Radio Club (MARC) has recently received permission to install equipment at the Government of Guam-maintained Emergency Operations Center (EOC). Built almost entirely underground, the EOC is virtually impervious to most natural disasters. Although some antenna problems remain to be resolved, MARC members hope to have a recently-purchased Kenwood HF rig and 2-meter gear installed before the next typhoon season.

When a typhoon is determined to be within 48 hours of possibly passing over Guam, the emergency coordinator calls the "Typhoon Net" on 2 meters. At that time, a survey of available personnel, equipment, and anticipated needs is made. With constant 6-hour updates from the Naval Oceanographic Command Center on Nimitz Hill, Guam, a constant watch is kept on the approaching storm. The hams on Saipan, approximately 100 miles north of Guam, are advised of the storm's location and forecast track via the 2-meter repeater, and hams on other more distant islands are kept posted by the Inter-Island Net that meets on 14,315 kHz.

Here on Guam, a detailed communications plan assigns a ham to the commissioner of each village—or to a group of several nearby villages—to assist him. Two meters, of course, is the standard band for operations, utilizing the .34/.94 repeater as well as .52 simplex.

For communications off-island, the normal terminus is with Hawaii. Frequencies for CW and SSB as well as RTTY have been assigned to handle health and welfare traffic, as well as government messages if asked to do so.

In order to stay proficient at emergency procedures, MARC members regularly volunteer to assist local civic groups by providing communications services for a wide variety of events. These include bike rides, walkathons, marathons, and several offshore marine events between the southern island village of Merizo and nearby Cocos Island.

In spite of all these preparations, though, the emergency communications system on Guam is not without its problems. With a large percentage of the ham population in the military, it is difficult for the Emergency Coordinator to build a steady and dependable core of operators to activate during an emergency. In the event of a typhoon, most military people are called in to their work posts for duty until the storm passes. Frequent transfers of personnel make for a constantly-fluctuating population of operators.

As has so often been the case with hams and emergency communications, the key to successful response and operations must continue to be flexibility and creativity mixed with plenty of hard work.

CANADA

Some time ago it was suggested to the Department of Communications (DOC) that there could be a number of advantages to an arrangement whereby amateurs assisted in the conduct of examinations. CARF (Canadian Amateur Radio Federation) raised the matter again with the DOC last summer. Since then, the Department has been considering the possibility of such an arrangement and the result has been a letter addressed to CARF president Don Slater VE3ID. The letter requested "detailed input" from CARF on areas pertaining to amateur participation, including minimum criteria for amateur examiners, the selection process, the maintenance of examination integrity, exam distribution, and coordination between the DOC and amateur examiners.

Some ideas for amateur participation have been discussed in recent issues of *TCA* and comment was sought from readers, but to date the response has not been exactly overwhelming. Now, however, the DOC has asked specific questions and is seeking answers from CARF and other organizations. In order to ensure that varying ideas and views are incorporated in the recommendations in the CARF brief to the DOC, comments from clubs and individuals are now urgently sought.

In other action, the DOC approved a request for commemorative prefixes for World Communications Year. Starting on World Communications Day, May 17, through July 17 (inclusive), CY may be used for VE, CI for VO, and CK for VY.

The department has also proposed new regulations covering the radio noise generated by power lines and sub-stations. The first-ever regulations are designed primarily to protect AM sound broadcasting, but obviously they would benefit amateurs as well. The proposed rules are complicated and require special measuring equipment. Amateurs who are interested in this very technical proposal may get a copy from a DOC office. Ask for Notice Delta Golf Tango Roger—021-82.

However, not all of the amendments to the Canadian amateur regulations proposed a year ago have been processed. They would permit repeater operation in the 29-MHz band, SSTV in the HF bands, 6-MHz bandwidth for ATV, and more power on 160 meters. The amendments also would allow foriegn amateurs from countries with reciprocal agreements to operate in the full two-meter band. Currently in the legal mill of the department are the 160-meter power change, deletion of mobile logging, and a provision for amateur-class operators in

remote districts to operate with Advanced privileges on a conditional basis.

Brazil

PROCEDURES TO GET A BRAZILIAN LICENSE

If your country has a reciprocity agreement with Brazil, you have to present your original amateur license and your passport to DENTEL (Department of Communications), which has offices in all capital cities, and fill out form DNT-143. The license will be issued with a special callsign which has the letter Z after the number; for example: PY1ZXY. The license will be valid for the period of time which you will stay in Brazil or until the date your original license expires, whichever comes first.

During the valid term of the license, you do have to be a member of the Brazilian Amateur Radio League—LABRE. You may contact the League first, and they will be very kind in helping you to get your Brazilian license. Write to the League office in the state to which you are going (see box).

AWARDS

Sponsored by the Rio de Janeiro CW Group, the CWRJ Award is available to all licensed amateurs for confirmed contacts with 20 (twenty) different PY1 stations, including at least 5 (five) CWRJ members. Contacts must have been made after December 16, 1980, on any amateur band. Only two-way CW mode. No QSLs. Send GCR log of stations worked (call, date, time, band, mode, and report) and 10 IRCs for mailing expenses to CWRJ, PO Box 621, 24000 Niterio, RJ, Brazil.

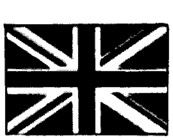
Endorsements are given for each 20 new PY1 confirmed contacts which include one new CWRJ member. CWRJ members: PY1ÁFA, PY1AFG, PY1AJK, PY1ASI, PY1BFZ, PY1BGI, PY1BMF, PY1BOA, PY1BOQ, PY1BUG, PY1BUL, PY1BVY, PY1CBW, PY1CC, PY1CCX, PY1CCY, PY1DCG, PY1DEA, PY1DFF, PY1DGB, PY1DN, PY1DIN, PY1DJY, PY1DPG, PY1DUH, PY1EBK, PY1EWN, PY1FB, PY1HO, PY1LG, PY1MHO, PY1MKA, PY1RJ, PY1UET, PY1VB, PY1VLR, PY1VOY, PY1WDS, PY1WO.

The CWRJ sponsors seven more awards: the Brazilian Stations Award (BSAW), Rio de Janeiro State Cities Award (RJCAW), Geographic Brazil Award (BGAW), Worked CWRJ Associate Members Award (WAMAW), Brazil's Frontiers Award (BFAW), CWRJ YL Flowers Award (YLAW), and the Worked CWRJ Award (WRJA).

Please note that my PO Box number was printed incorrectly last month and that the correct one (12178) appears above.

LEAGUE ADDRESSES

LABRE/CENTRAL—SCS-SUL-Trecho 04-Lote 1-A-Brasilia, DF.
LABRE/ACRE—Rua Benjamin Constant s/nº-Ed. Abrahim Sala 308, 3º andar-Rio Branco, AC.
LABRE/ALAGOAS—Ladeira da Catedral, nº 150-Maceió, AL.
LABRE/AMAZONAS—Rua Franco de Sá, 118-Adrianópolis-Manaus-AM.
LABRE/BAHIA—Rua Santa Rita Durão, s/nº-Forte do Monte Serrat-Salvador, BA.
LABRE/CEARÁ—Travessa Pará, 12, Ed. Sul América, sls. 703/704-Fortaleza, CE.
LABRE/ESPÍRITO SANYO—Rua Alberto Oliveira Santos, 59-s/711-Vitória, ES.
LABRE/GOIÁS—Rua do Radioamador, 247-Setor Coimbra-Goiânia, GO.
LABRE/MATO GROSSO—Rua Gen. Valle, 32-Cuiabá, MT.
LABRE/MATO GROSSO DO SUL—Rua Sargento Yulle, 50-Campo Grande, MS.
LABRE/MARANHÃO—Rua Osvaldo Cruz, 340, Ed. Duas Nações, s/112-São Luiz, MA.
LABRE/MINAS GERAIS—Rua N. S. do Carmo, 221, salas 307 a 309-Belo Horizonte, MG.
LABRE/PARÁ—Trav. padre Eutiquio, 719-Belém, PA.
LABRE/PARAIBA—Av. Eng. Leonardo Arcoverde, s/nº-João Pessoa, PB.
LABRE/PARANÁ—Rua Voluntários da Pátria, 475, 9º andar-s/909-Curitiba, PR.
LABRE/PERNAMBUCO—Av. Agamenon Magalhães, 2945-Recife, PE.
LABRE/PIAUÍ—Rua Álvaro Mendes, 1450-Teresina, PI.
LABRE/RIO GRANDE DO NORTE—Av. Rodriques Alves, 1004-Tirol-Natal, RN.
LABRE/RIO GRANDE DO SUL—Rua Dr. Floras, 62, 13º andar-Porto Alegre, RS.
LABRE/RIO DE JANEIRO—Av. Treze de Maio, 13, 20º andar, sala 2018-Rio de Janeiro, RJ.
LABRE/RONDÔNIA—Av. Falqhuar, 2230-Porto Velho, RO.
LABRE/RORAIMA—Av. Getulio Vargas, 25 W, sala 2, Altos-Boa Vista, RR.
LABRE/SANTA CATARINA—Rua Jerônimo Coelho, 325, Conj. 110, Ed. Julieta-Florianópolis, SC.
LABRE/SÃO PAULO—Largo de S. Francisco, 34, 11º andar-São Paulo, SP.
LABRE/SERGIPE—Largo dos Radioamadores, s/nº-Aracaju, SE.



GREAT BRITAIN

Amateurs in Great Britain are enjoying the recently-released *G-QRP Club Circuit Handbook*, edited by G-QRP club president, Rev. George Dobbs G3RJV. The *Handbook* has over 100 pages of QRP circuits compiled from *Sprat*, the club's newsletter. Eight years of circuits and ideas, from 1974-1982, have been included in the book. Newcomers and old-timers alike have been finding useful new circuits, as more British hams are discovering QRP. Amateurs interested in finding out more about this collection of QRP know-how should write to Alan Lake G4DVW, Middleton Cl., Nuthall, Nottingham NG16 1BX, Great Britain.

DX CONTESTING—BAHRAIN STYLE!

Casting around for something useful to do one Friday (a Bahrain Friday equates to an American Sunday) not too long ago, a group of our erstwhile DX chasers gravitated to bandying words over 2-meter repeater A92RP. Replete no doubt with a good curry lunch, someone (he wishes to remain anonymous) voiced the thought that it would be "a very good idea" if the Association were to participate in the upcoming CQ WW Phone DX Contest—due to commence in a few hours time, on that Saturday morning! It was claimed that no prior contest experience was called for, but merely the ability, dedication, stamina, and willingness necessary to carry the enterprise forward to a successful conclusion. In the ensuing discussion, a consensus emerged in favor of the idea.

Suitably fired with enthusiasm and lulled no doubt by honeyed words into a false sense of security, our band of contest warriors repaired to the clubhouse; most were armed with those extra pieces of equipment individually deemed essential to the success of our communal endeavor. The capability of the already-installed club FT-101B transceiver and triband beam was to be enhanced by the addition of a KW-1000 linear amplifier—which promply resulted in cooking the coil in the 200-Watt-rated Daiwa antenna coupler! An 830S was produced with the comment that "perhaps we can manage simultaneous operation on two bands," but this of course would require a second antenna.

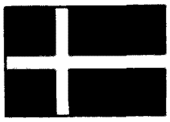
It was by this time becoming dark, so the stringing up of a trap dipole for the LF bands between our own mast and that of our landlord took place after dark. Not surprisingly, the end result when viewed in the light of the following day caused some small degree of concern—our mast had acquired a most definite southbound lean due, no doubt, to the combination of dipole and feeder weight plus over-enthusiastic late-night rigging efforts!

Whilst much of the preceding action was in progress, when the equipment was not under repair or the mast folded over for antenna work, those not otherwise gainfully occupied were conducting a radio advertising campaign, advising all interested contacts of our contest entry. Starting on 21 MHz, they moved successively to 28, 14, and 3.8, and then back to 14 in time to warm up with a few pre-contest QSOs.

Operations continued as dictated by operator availability—always a problem with our different weekend arrangements and, on this occasion, compounded by the fact that not everyone realized that it was a 48-hour contest.

How did we do? Results were reasonable: over 1050 QSOs with 60 countries spread over 5 bands, thanks to the efforts of Sheridan (A92BE), Dhiya (A92DQ), Jon (A92F), Keith (A92P), and John (A92Z).

What did we learn? Other than the obvious and fortunately minor equipment problems, we were not terribly good logkeepers with respect to frequently entering QSO times and the bands on which they were made. Poor Keith had a terrible time attempting to transcribe the log onto the summary sheets and finally had to admit defeat. We won't appear in any listing, but did most definitely have a barrel of fun. Now with all those in-house experts, perhaps the 1983 event ought to be a lot less traumatic!



DENMARK

Denmark

There are about 10,000 licensed radio amateurs in Denmark, but I think that only half are active on the bands. There are four license categories and most amateurs here hold a D license which allows them to work on the VHF and UHF bands with 100 Watts. The D license requires only a simple technical test and most students pass the test.

Then we have the C license, for which the technical test is the same as for the D license, but there is also a CW test. The radio amateur with a C license can work on the HF bands, but only CW with 10 W of power. However, C-class amateurs retain D-class privileges on VHF and UHF.

The next category is the B license, which requires possession of a C license for one year or an extended technical test. In both cases, it is necessary to pass a CW test. The B license allows you to work on all the amateur bands with 100 W in all modes.

And last, we have the A license, which requires a B license for one year and allows working with 500 W (0.5 kW!) on all amateur bands and with all modes.

The CW test is given at 12 wpm.

The amateur bands in Denmark are the following:

- 3.500-3.800 MHz (3.5-3.6 MHz CW only).
- 7.000-7.100 MHz (7.0-7.01 MHz CW only).
- 14.000-14.350 MHz (14.0-14.1 MHz CW only).
- 21.000-21.450 MHz (21.0-21.15 MHz CW only).
- 28.000-29.700 MHz (28.0-28.1 MHz CW only).
- 144.000-146.000 MHz (All modes—Reg. 1 band-table).
- 432.000-438.000 MHz (All modes—Reg. 1 band-table).

Danish amateurs can also use the "new" bands (CW only): 1.830-1.850 MHz, 10.100-10.150 MHz, 18.068-18.168 MHz, and 24.890-24.990 MHz.

After receiving a special permit, we may also use the following UHF and SHF bands (all modes): 1215-1300 MHz, 2300-2450 MHz, 5650-5850 MHz, 10.0-10.5 GHz, and 24.0-24.25 GHz.

All radio amateurs can work with homemade stations or with factory toys on all amateur bands, but if one wants to work on the citizens band (27 MHz), one must buy a factory-made station (maximum, 500 mW) and the station must be approved by the Post- and Teleadministration.

Denmark is a little country with about 5 million citizens, but we have a very developed electronics industry and everywhere we look, we see radio amateurs in leading positions.

Radio amateurs are mostly popular in Danish society, but we naturally have problems with hi-fis and video recorders, but our good contacts in the electronics industry can in many cases solve our problems.

This was a little about Denmark and its radio amateurs—in my next column, I will write a little about the Danish radio amateur society, the EDR.

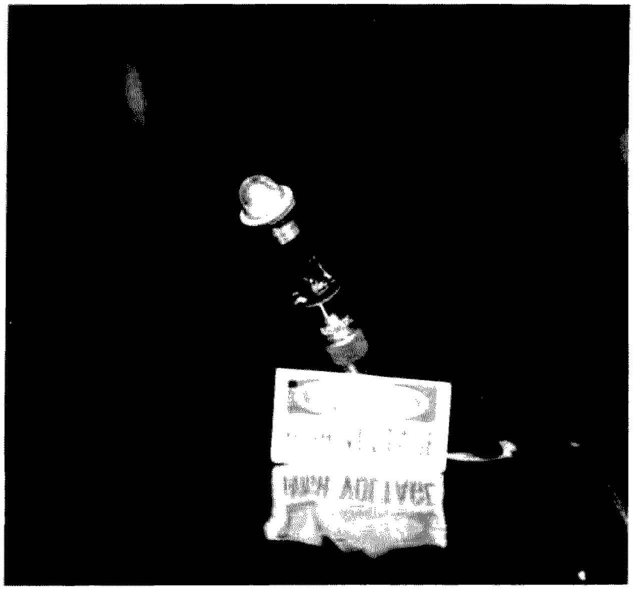
73¢ for a Voltage-Transient Detector

Forget those expensive and complex insurance policies. Here's the best protection you can get—and the cheapest.

Being a doubting Thomas by nature, I have often wondered about the necessity of those antenna surge protectors as advertised in the amateur press. As you know, those surge shunts as advertised are to proect solid-state communications equipment from damage caused by voltage transients entering the antenna system. Those usually are caused by atmospheric static discharges or nearby lightning strikes—according to the ads. The purpose of this article is to show you how these gremlins can be readily detected.

I am not doubting the claims of the advertisers. As any old reader of this magazine can attest, *NO* advertiser would dare to sell anything not up to its claims in this magazine. The shyster would become the object of Mr. Green's unmentionable and merciless wrath. Period. Even in light of these facts, I continued my search for proof.

The first objective was to prove visually the existence of voltage transients. Recalling from my Novice days the fact that neon bulbs glow in the presence of high voltage, I decided to utilize this method of approach. Thus, I reasoned that a neon bulb across the coax plug—disconnected, of course—would reveal the nasty little gremlins.



Neon pilot-lamp assembly.

As you can clearly see, simplicity is the nucleus of the circuit shown in Fig. 1. The parts required are readily available at any nearby hamfest flea market. After comparing many entrepreneurs' offerings of neon pilot-lamp assemblies, I found the one in the photo for a mere twenty-five cents—used, of course (both the quarter and the pilot-lamp assembly). Needless to say, all it lacked was an NE-51 bulb. The latter was obtained for an additional quarter.

Now for connecting my coax to the assembly. A clean RCA phono jack was found at another entrepreneur's stand of irresistible bargains for another quarter. Reaching into my pocket, I came up with two dimes and only three pennies. "It's a deal!" cried the businessman. Total investment? You guessed it . . . 73¢!

After what seemed a long ride home, I headed straight for the workbench (the scene of many electronic tribulations and tests). With the smell of hot solder filling the air and a period of five quick minutes, the tester became reality.

Next, I disconnected the coax connector (via a PL-259 to an RCA-type adapter) from the rig and terminated the coax into the antenna-voltage-transients detector. Did the neon glow? No. As a matter of fact, nothing happened.

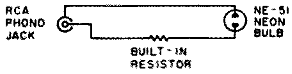


Fig. 1. One scientific circuit for detection of antenna voltage transients.

However, a few nights later while chasing some rare DX on 15 CW, a usually unwelcomed sound of key-rashing ! + #%!!! noise filled the headphones! Ah, an approaching thunderstorm! Quickly! Disconnect the coax from the rig! Terminate into the 73¢ wonder! Eureka! There it was, flashing away before my very eyes! Success. The neon bulb was flashing its heart out as the thunderstorm approached. Success.

In the interest of a longer life here on Earth, I disconnected the coax and grounded everything. Be very careful when doing this . . . it is not my intention to send any readers to Silent Key land after building and using one of these 73¢ detectors. There is a high-voltage hazard present, so use your common sense and disconnect as the neon gets brighter. Also, keep the bulb cover on the assembly in case the neon bulb should break. And be sure to check for a built-in resistor in your neon pilot-lamp assembly—otherwise your NE-51 will fire its last and first time forever. Good luck and good viewing—but be careful. And yes, the ads are correct; those gremlins do indeed exist. ■

Build the Armchair Satellite Tracker

Simple and cheap, this setup will follow OSCAR around like a dog. Put it together, lean back, and let this control system do the work for you.

Editor's Note: This ingenious tracking system can be used for satellites like UoSAT and Russian "RS" amateur birds as well as the ever popular OSCAR 8.

This article describes a fully-automatic system for tracking satellites in low, near-circular orbits such as that of OSCAR 8. The system requires as little as one rotator and a very simple rotator-control unit. Normally, two rotators will be desired, but they are not necessary to achieve fully-automatic tracking with fairly good accuracy. This system eliminates problems associated with conventional antenna-pointing systems such as high cost, complexity, and large tracking errors.

Photo A. The completed system. The tilt axis is positioned for a near-horizon satellite pass. This position may also be used for terrestrial operations using the elevation rotator as a conventional azimuth rotator.

Conventional systems are based on a system of azimuth and elevation settings. Some are computer-controlled and some use a computer-generated chart with manual adjustment of the controls of the two rotators. One system uses a single azimuth rotator with the antenna pointed about 30 degrees above the horizon. Pointing errors reach as much as 60 degrees with this system.

There is one reason common to all of these systems that makes for complexity, high cost, or marginal results: They all are based on a reference system which is parallel and perpendicular to the surface of the Earth while the satellite's orbital plane is normal to some other reference system. Conventional antenna-

pointing systems are always bucking this natural motion of the satellite. My system attempts to align the reference plane of the antenna rotator with the reference plane of the satellite. It is not perfect; it is not designed for the purist who has access to megabyte computers and megabuck wallets. It is designed for the amateur who is a casual operator but desires some sophistication and moderately good accuracy.

To obtain some idea of how my system works, let us discuss the special case of the direct overhead pass and the conventional azimuth/elevation system. Let's say the satellite is ascending, has a polar orbit, and will be above the horizon for 16 minutes. The satellite will rise in the south (bearing 180 degrees), pass directly overhead 8 minutes later, and set to the north (bearing 360 degrees) sixteen minutes after acquisition.

If we had set our elevation rotator to point at the horizon and the azimuth rotator to a bearing of 180 degrees, we could have tracked the satellite just by operating the elevation rotator only. We would start with the antenna pointing at the southern horizon, slowly rising through the vertical as the satellite passed overhead, and on to the northern horizon. In this special case, the plane of the orbit coincides with the plane described by the movement of the elevation rotator.

Next, let's examine a more common case of an other than direct overhead orbit. Imagine an orbit where the satellite reaches a maximum elevation of 60 degrees to the east of your QTH. We will start off with the conventional azimuth/elevation system by setting the azimuth rotator to a bearing of 180 degrees and the elevation rotator to point at the southern horizon. Again, the antenna will be pointing at the satellite when it rises, but if we tried to track it as in the last example, we would soon have a large tracking error. By the time the antenna reached the vertical position, the satellite would be 30 degrees away toward the east. Continuing on to the northern horizon, the pointing error would gradually decrease with the antenna again pointing at the satellite as it set to the north.

Now let's go through the last example again, only we will make an adjustment to the antenna-mounting system which will alter the results considerably. With the antenna pointing at the southern horizon, remove the azimuth rotator and mount the elevation rotator on an axle which is parallel to the surface of the Earth and aligned north-south. The elevation rotator is now free to tilt to the east or west. If we tilt the elevation rotator so that what used to be the azimuth mast is now aimed at a point 60 degrees above the eastern horizon, we will change the entire geometry of the tracking system. We lock the new axle in the 60-degree position and begin the satellite

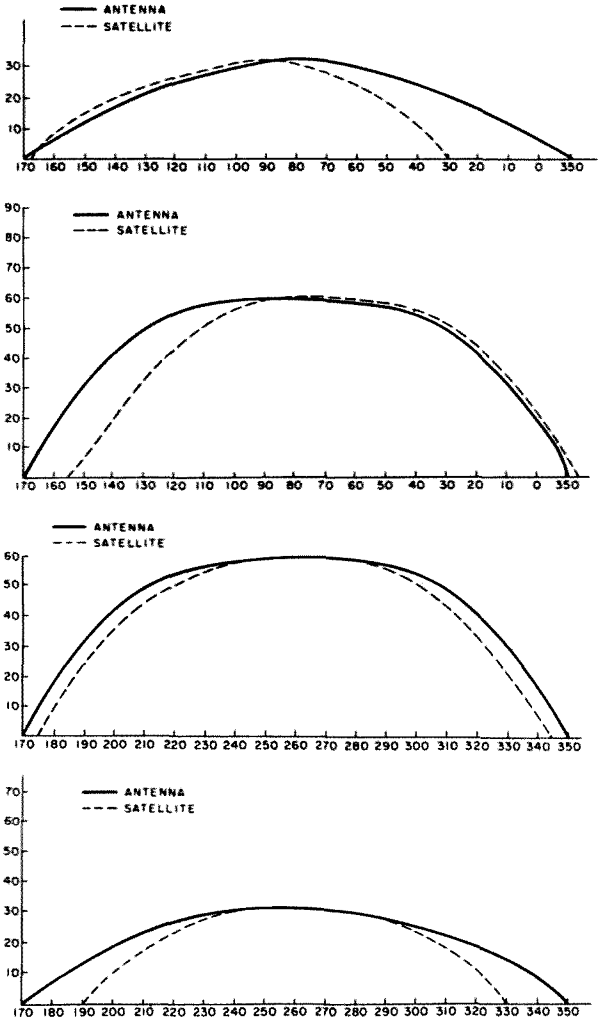

Fig. 1. Charts of relative bearings and elevations of OSCAR 8 compared to the antenna-pointing position. All satellite coordinates are for ascending orbits and a QTH latitude of 42 degrees north. Antenna-pointing positions, above, top to bottom: 30° East, 60° East, 60° West, and 30° West.

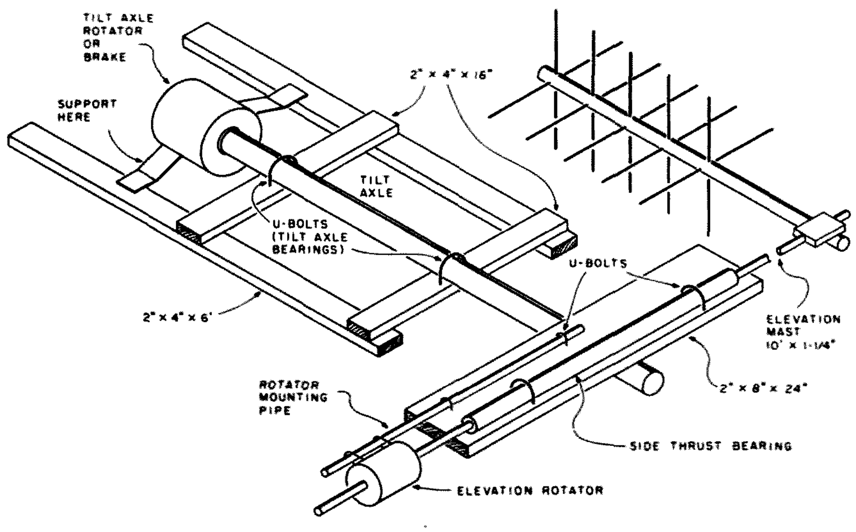

Fig. 2. Antenna/rotator assembly with antenna oriented to begin an overhead pass.

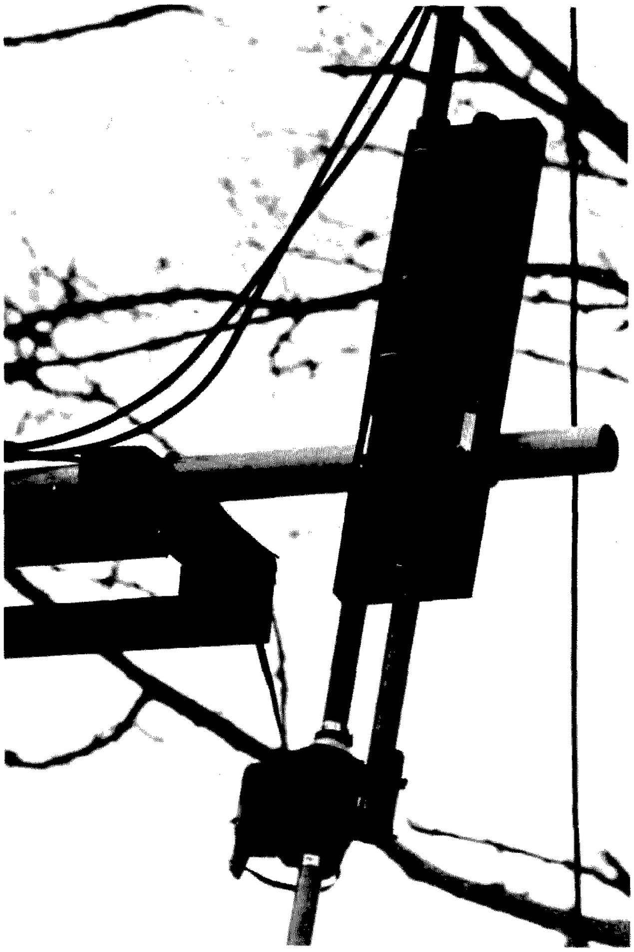

Photo B. Close-up view of the elevation rotator mounting board. Note the method of mounting. A small tab must be removed from this type of rotator in order to mount it right-side up.

pass. As the satellite rises and travels toward the midpoint of its arc, the elevation rotator is activated. Instead of moving to the vertical position, the antenna will closely follow the satellite. We have tilted the plane described by the elevation rotator so that it nearly coincides with the plane of the orbit. To the elevation rotator, the satellite appears to be making an overhead pass.
